

Solutions of the problem of Erdős-Sierpiński: $\sigma(n) = \sigma(n + 1)$

Lourdes Benito

lourdes.benito@estudiante.uam.es

Abstract

For $n \leq 1.5 \cdot 10^{10}$, we have found a total number of 1268 solutions to the Erdős-Sierpiński problem finding positive integer solutions of $\sigma(n) = \sigma(n + 1)$, where $\sigma(n)$ is the sum of the positive divisors of n . On the basis of that set of solutions the following empirical properties are enunciated: first, all the $\sigma(n)$, n being a solution, are divisible by 6; second, the repetition of solutions leads to the formulation of a new problem: *Find the natural numbers n such that $\sigma(n) = \sigma(n + 1) = \sigma(n + k) = \sigma(n + k + 1)$ for some positive integer k .* A third empirical property concerns the asymptotic behavior of the function of n that gives the number of solutions for m less or equal to n , which we find to be as $n^{1/3}$. Finally some theorems related to the Erdős-Sierpiński problem are enunciated and proved.

1 Introduction

The problem of determining the natural numbers n that verify

$$\sigma(n) = \sigma(n + 1) \tag{1}$$

Where $\sigma(n)$ is the sum of the positive divisors of n , is known as the Erdős-Sierpiński problem.

Erdős [Erdős 1945] had conjectured that there are infinitely many solutions to the (1) but he offered no proof. Some time later, Sierpiński [Sierpiński 1964] posited the same question.

The first natural numbers that satisfy (1) are:

$$n = 14, 206, 957, 1334, 1364, 1634, 2685 \dots$$

This sequence is identified as the A002961 sequence by the Sloane's On-Line Encyclopedia of Integer Sequences.

Guy [Guy 2004] , B13, communicates that Jud McCranie calculated solutions for the problem of Erdős-Sierpiński up to $n = 4.25 \cdot 10^9$. A total of 832 solutions were found. We have investigated the solutions up to $n = 1.5 \cdot 10^{10}$ (see D), and found a total of 1268 solutions.

Guy and Shanks [Guy & Shanks 1974] observe that the solutions for $n = 14$, $n = 206$ and $n = 19358$ are given by:

$$n = 2p, \quad n + 1 = 3^m q, \tag{2}$$

where

$$q = 3^{m+1} - 4, \quad p = (3^m q - 1)/2$$

are both prime, and m equals 1, 2 or 4.

They also indicate that the solutions for $n = 18873$, $n = 174717$ and $n = 5559060136088313$ are given by

$$n = 3^m q, \quad n + 1 = 2p, \tag{3}$$

with the primes

$$q = 3^{m+1} - 10, \quad p = (3^m q + 1)/2$$

for $m = 4, 5$ and 16.

With the help of the two functions `guyshanks1(1,1000)` and `guyshanks2(1,1000)`, written in Pari-GP language [Cohen et al. 2003] (see A), it is verified that no other solutions of the forms (2) and (3) exist for $m \leq 1000$.

2 Some Empirical Results

On the basis of the set of solutions of the Erdős-Sierpiński problem for $n \leq 1.5 \cdot 10^{10}$, the following empirical results can be enunciated:

For n a solution to the Erdős-Sierpiński problem

- i) $\sigma(n)$ is divisible by 6.

ii) $\sigma(n)$ is divisible by 4 with the exception of:

$$\sigma(18873) = 28314 = 2 \cdot 3^2 \cdot 11^2 \cdot 13$$

iii) $\sigma(n)$ is divisible by 8 except the mentioned case ii) at the following ones:

$$\sigma(4364) = 7644 = 2^2 \cdot 3 \cdot 7^2 \cdot 13$$

$$\sigma(14841) = 22932 = 2^2 \cdot 3^2 \cdot 7^2 \cdot 13$$

$$\sigma(3582224) = 6976860 = 2^2 \cdot 3 \cdot 5 \cdot 11^2 \cdot 31^2$$

$$\sigma(195694137) = 293616180 = 2^2 \cdot 3^2 \cdot 5 \cdot 11^2 \cdot 13 \cdot 17 \cdot 61$$

$$\sigma(597311577) = 896138100 = 2^2 \cdot 3^3 \cdot 5^2 \cdot 11^2 \cdot 13 \cdot 211$$

iv) The only $\sigma(n)$ of the form $2^a \cdot 3^b$ with a and b natural numbers are:

$$\sigma(14) = 24 = 2^3 \cdot 3$$

$$\sigma(147454) = 221184 = 2^{13} \cdot 3^2$$

2.1 A new problem

If the solutions to the Erdős-Sierpiński problem are carefully examined, it will be observed that certain values are repeated. Therefore, a related problem can be enunciated:

Problem 1. Find the natural numbers n that verify

$$\sigma(n) = \sigma(n + 1) = \sigma(n + k) = \sigma(n + k + 1)$$

for some positive integer k .

For $n \leq 1.5 \cdot 10^{10}$, 22 solutions to this problem have been found (see C). The smallest solutions is: $\sigma(79826) = \sigma(79827) = \sigma(79833) = \sigma(79834) = 120960$.

$\sigma(n) = 4049740800$ has three different solutions. In this case, the problem can be enunciated in a different way:

Problem 2. Find the natural numbers n that verify

$$\sigma(n) = \sigma(n + 1) = \sigma(n + k) = \sigma(n + k + 1) = \sigma(n + k') = \sigma(n + k' + 1)$$

for some pair of positive integer numbers k and k' .

2.2 Estimation of the number of solutions to the Erdős-Sierpiński problem

Figure 1: Number of solutions for (1) less or equal to n versus n . Dashed lines correspond to $y_1 = 0.5 \cdot n^{\frac{1}{3}}$ and $y_2 = 0.55 \cdot n^{\frac{1}{3}}$. The maximum value of n for which the number of solutions is over y_1 is $n = 258083942$, and the maximum value of n for which the number of solutions is below y_2 is $n = 2305557$.

In order to give an estimation of the number of solutions, different fit functions were tried, and the best fit obtained was in the form $\sim n^{\frac{1}{3}}$.

Then, it is found that, for $258083942 < n < 1.5 \cdot 10^{10}$ the number of solutions lies between y_1 and y_2

$$\begin{cases} y_1 &= 0.50 \cdot n^{\frac{1}{3}} \\ y_2 &= 0.55 \cdot n^{\frac{1}{3}} \end{cases}$$

If a linear adjustment based in $n^{\frac{1}{3}}$ is made, we get:

$$y_{adj} = 0.5088 \cdot n^{\frac{1}{3}} + 6.9183$$

where y_{adj} is the number of solutions less or equal to n that predicts the adjustment (see figure 2).

For example, an estimation of the number of solutions up to $n = 10^{15}$ to the Erdős-Sierpiński problem is: $0.5088 \cdot 10^{15 \cdot \frac{1}{3}} + 6.9183 \approx 5 \cdot 10^4$ solutions.

Figure 2: On the left, both the number of solutions less or equal to n (continuous line) and the linear adjustment (dashed line) are plotted versus $n^{1/3}$. On the right, it is represented the relative error (ϵ) corresponding to the adjustment. $\epsilon = \frac{y - y_{adj}}{y}$, where y is the number of solutions less or equal to n and y_{adj} is the number of solutions that predicts the adjustment. From $n = 792855$ ($n^{1/3} = 92.5546$) the relative error is smaller than 10% ($|\epsilon| < 0.1$).

3 Some theorems

Theorem 1. $\sigma(n)$ is odd if and only if n is a square, or n is the double of a square.

Proof.

- If p is prime and $p \neq 2 \Rightarrow \sigma(p^\alpha) = 1 + p + p^2 + \dots + p^\alpha \equiv \alpha + 1 \pmod{2}$, then for $\sigma(p^\alpha)$ to be odd, α must be even.
- If $p = 2 \Rightarrow \sigma(2^\alpha) = 1 + 2 + \dots + 2^\alpha$ is always odd.

Then for $\sigma(n)$ to be odd, in the decomposition in prime factors of n , the power of the primes $p > 2$ must be even. Therefore, n is a square number or a 2-square number. \square

Theorem 2. For every natural number n that verifies $\sigma(n) = \sigma(n+1)$, $\sigma(n)$ is multiple of 2 or 3.

Proof. If $\sigma(n)$ is odd, from theorem 1 and, since two consecutive positive integer numbers cannot be both square, either n must be square and $n+1$ is the double of a square or n is the double of a square and $n+1$ is a square.

Then if $\gcd(x, 2) = 1$, $\sigma(2^{2\alpha+1} \cdot x^2) = \sigma(2^{2\alpha+1}) \cdot \sigma(x^2) = (1 + 2 + 2^2 + \dots + 2^{2\alpha+1}) \cdot \sigma(x^2) = (1 + 2 + 2^2(1 + 2) + \dots + 2^{2\alpha}(1 + 2)) \cdot \sigma(x^2) = 3 \cdot (1 + 2^2 + 2^4 + \dots + 2^{2\alpha}) \cdot \sigma(x^2)$. \square

Theorem 3. *If n is a positive integer such that $\sigma(n) = \sigma(n+1)$ is odd, then:*

$$n = 2y^2, \quad n + 1 = x^2 \quad \text{with } x^2 - 2y^2 = 1$$

or

$$n = x^2, \quad n + 1 = 2y^2 \quad \text{with } x^2 - 2y^2 = -1,$$

where x and y are integer numbers.

Proof. From to theorem 1 if $\sigma(n)$ is odd, then n must be square or 2-square. If n is odd, then $n = x^2$, and $n + 1 = 2y^2$ because two consecutive positive integers cannot be both square numbers. Therefore $x^2 - 2y^2 = -1$.

If n is even then $n = 2y^2$, and $n + 1 = x^2$. Therefore $x^2 - 2y^2 = 1$. \square

Using a Pari-Gp [Cohen et al. 2003] function (see B) based on the ideas of [Benito & Escribano 1998] we have verified that there is not any solution to the problem of Erdős-Sierpiński in which $\sigma(n)$ is odd for $n < 10^{50}$.

4 Open questions

1. The numerical evidences described in section 2.2, agree with the conjecture of Erdős about the existence of infinite n that satisfy $\sigma(n) = \sigma(n + 1)$. These evidences allow us to conjecture that the number of solutions less or equal than n is of the order of $n^{\frac{1}{3}}$.
2. Apart from those mentioned, do any other solutions to the Erdős-Sierpiński problem of forms (2) and (3) exist?
3. Does any n for which $\sigma(n) = \sigma(n + 1) \neq \dot{2}$ exist?
4. Does any n for which $\sigma(n) = \sigma(n + 1) \neq \dot{3}$ exist?
5. Apart from those mentioned, do any other solutions to the Erdős-Sierpiński problem in the form $\sigma(n) = \sigma(n + 1) = 2^a \cdot 3^b$ exist?
6. Do infinite solutions to problem 1 exist?
7. Apart from those mentioned, do any other solutions to the problem 2 exist?

A Numerical code used in section 2

Below the reader will find the code of the Pari-Gp function that verifies that there are not more solutions of form (2) for values of m less than 1000.

```
q(m)=3^(m+1)-4
```

```
p(m)=(3^(2*m+1)-4*3^m-1)/2
```

```
guysshanks1(k1,k,i)=  
  {  
    for(i=k1,k,  
      if(isprime(q(i)),  
        if(isprime(p(i)), print(i," ",2*p(i))," ",3^i*q(i))  
      ,)  
    )  
  }
```

And the code for the Pari-Gp function that verifies that there are not more solutions of form(3) for values of m less than 1000.

```
q(m)=3^(m+1)-10
```

```
p(m)=(3^(2*m+1)-10*3^m+1)/2
```

```
guyshanks2(k1,k,i)=  
{  
  for(i=k1,k,  
    if(isprime(q(i)),  
      if(isprime(p(i)),print(i," ",3^i*q(i)," ",2*p(i)),)  
    ,)  
  )  
}
```

B Numerical code for theorem 3

```
noteven(k,z,t,a)=  
{ z=1;  
  while(denominator(z)<k,z=2+1/z;t=1+1/z;  
    a=sigma(denominator(t)^2);  
    if(a==sigma(numerator(t)^2\2),  
      print(denominator(t)^2," ",numerator(t)^2\2," ",a),)  
    )  
}
```
