Convex geometries representable by at most 5 circles on the plane

PolyMath REU-2020, Convex Geometries Team*

July-August 2020

Abstract

A convex geometry is a closure system satisfying the anti-exchange property. In this work we document all convex geometries on 4- and 5-element base sets with respect to their representation by circles on the plane. All 34 non-isomorphic geometries on a 4-element set can be represented by circles, and of the 672 geometries on a 5-element set, we made representations of 621. Of the 51 remaining geometries on a 5-element set, one was already shown not to be representable due to the Weak Carousel property, as articulated by Adaricheva and Bolat (Discrete Mathematics, 2019). In this paper we show that 7 more of these convex geometries cannot be represented by circles on the plane, due to what we term the Triangle Property.

1 Introduction

This project was done during two summer months of 2020 within the framework
of the Polymath REU project, which brought together undergraduate students
from around the world who worked together online to make progress on 12
different mathematical problems.

In this project we address the problem raised in Adaricheva and Bolat [1]:
whether all geometries with convex dimension at most 5 are representable by
circles on the plane using the closure operator of convex hull for circles.

The early survey on the topic of convex geometries is given by Edelman
and Jamison [7], and the theory of infinite convex geometries was developed
in Adaricheva, Gorbunov, Tumanov [2]. A recent survey on the topic, which
includes both finite and infinite convex geometries, is in a chapter of *Lattice
Theory: Special Topics and Applications* (2016), by Adaricheva and Nation [3].

The representation of finite convex geometries by circles was introduced by
G. Czédli in [6], where the usual closure operator of convex hull acting on
sets of points was generalized to the convex hull operator acting on circles.

Moreover, he proved that every finite convex geometry of convex dimension 2 can be represented by circles on the plane.

The natural question of whether a finite convex geometry of any convex dimension can be represented by circles on the plane was answered in [1] *in the negative*: it turns out that the convex hull operator acting on circles in the plane satisfies a condition called the 2×3-*Weak carousel property* - and not all finite convex geometries satisfy it. An example of a geometry with a convex dimension of 6 that does not satisfy this condition was found on a 5-element set.

This left the question of whether any convex geometry on an at most 5-element set, with convex dimension at most 5, could be represented by circles on the plane.

The goal of the project was to document all convex geometries on 4- and 5-element sets, to show their representations by circles (when possible), and to describe the features of "impossible" geometries.

After generating the list of all geometries on 4- and 5-element sets, we found representations of all 34 non-isomorphic geometries on 4-element sets and of 621 geometries on 5-element sets. 51 geometries on a 5-element set resisted representation by circles.

Geometry G4 from the list of 672 non-isomorphic geometries on a 5-element set is the "impossible" geometry shown not to be representable in [1]. In this paper we prove that 7 more geometries from the list of 672 are not representable. The proof is based on the Triangle Property (Lemma 5 in section 9).

Three geometries from this new set of "impossible" geometries have a convex dimension of 4, and one has a convex dimension of 5. **This provides a solution to Problem 1 in [1] in that geometries not representable by circles exist with those convex dimensions.**

On the other hand, all geometries on 4- and 5-element sets with convex dimension 3 are represented by circles. Thus, the following question remains:

Question 1. *Does there exist a convex geometry of convex dimension 3 not representable by circles on the plane?*

The paper is organized as follows. We provide all necessary definitions related to convex geometries in section 2. In particular the parameter of *convex dimension* is explained in detail. Section 3 provides the background for the algorithm generating all non-isomorphic geometries (anti-matroids) on n-element set, for values of n up to 7. The algorithm was developed around 2013, in the framework of enumerating anti-matroids in the On-line Encyclopedia of Integer Sequences (OEIS). The existing code was enhanced for computing the *implicational basis* of each geometry and its convex dimension. Sections 4 and 5 are devoted to methods for representing geometries by circles. Some basic principles of verifying representations are discussed in section 6. Sections 7 and 8 provide an overview of different software available for enhancing this area of mathematical work, in our case GeoGebra and Google Colab toolkit. Finally, section 9 gives the proof of the Triangle Property, and its consequences for a subset of "impossible" geometries not being representable by circles.

3

We provide two sets of appendices: in Appendix A there is a list of 34 geometries on 4-element set, and a list of 672 geometries on 5-element set, given by their alignments (convex sets), as well as sets of implications representing the associated closure operator. The meet-irreducible elements of alignments are provided, together with their maximal anti-chains, which allows the computation of each geometry's convex dimension.

Appendix B has representations by circles for all 34 geometries on a 4-element set, as well as 621 geometries on a 5-element set. The numbering corresponds to the order of geometries in the lists featured in Appendix A.

The last part of Appendix B lists 51 geometries which are not yet represented, giving their implicational bases, also featured in Appendix A. The list of geometries which we were not able to represent is as follows:

$G4, G7, G11, G12, G14, G15, G18, G21, G23, G26, G27, G33, G34, G35, G39, G43,$

$G45, G46, G47, G49, G54, G56, G57, G60, G62, G69, G70, G74, G84, G87, G88,$

$G89, G94, G95, G96, G105, G114, G115, G122, G129, G132, G134, G143, G147,$

$G153, G161, G175, G206, G211, G35, G351.$

Among these 51 geometries, we showed in this paper that the following are not representable by circles:

$$G7, G11, G12, G18, G21, G23, G34.$$

Excluding these 7 geometries, as well as earlier example G4 which cannot be represented, we ask:

Question 2. *Are 43 remaining geometries on the list above representable by circles on the plane?*

2 Preliminaries

2.1 Basic Definitions

A convex geometry is a special case of a closure system.

Definition 2.1. *Let X be a set and $\varphi \colon 2^X \to 2^X$ be a function. Then (X, φ) is a* closure system *if and only if for all $Y, Z \in 2^X$:*

1. *$Y \subseteq \varphi(Y)$*
2. *if $Y \subseteq Z$ then $\varphi(Y) \subseteq \varphi(Z)$*
3. *$\varphi(\varphi(Y)) = \varphi(Y)$*

Given a closure system (X, φ), refer to φ as its closure operator. *A subset $Y \subseteq X$ is* closed *if $\varphi(Y) = Y$.*

Definition 2.2. *A closure system $(X, \mathcal{F})$ is called a* convex geometry *if*

4

1. $\varphi(\emptyset) = \emptyset$
2. *For any closed set $Y \subseteq X$ and any distinct points $x, y \in X \setminus Y$, if $x \in \varphi(Y \cup \{y\})$ then $y \notin \varphi(Y \cup \{x\})$.*

The second property in this definition is called the *Anti-Exchange Property*.

Definition 2.3. *Given any (finite) set X, an alignment on X is a family $\mathcal{F}$ of subsets of X which satisfies two properties:*

1. $X \in \mathcal{F}$
2. *If $Y, Z \in \mathcal{F}$ then $Y \cap Z \in \mathcal{F}$.*

Closure systems are dual to alignments in the following sense:

If (X, φ) is a closure system, then let $\mathcal{F} := \{Y \subseteq X : \varphi(Y) = Y\}$. Then $\mathcal{F}$ is an alignment.

If $\mathcal{F}$ is an alignment, then define $\varphi : 2^X \to 2^X$ in the following manner:
For all $Y \subseteq X$, let $\mathcal{C}_Y := \{Z \in \mathcal{F} : Y \subseteq Z\}$ and $\varphi(Y) := \bigcap_{Z \in \mathcal{C}_Y} Z$. Then (X, φ) is a closure system.

We can use this duality to provide another definition of a convex geometry.

Definition 2.4. *A closure system is a convex geometry if the corresponding alignment $\mathcal{F}$ satisfies the following two properties:*

1. $\emptyset \in \mathcal{F}$
2. *If $Y \in \mathcal{F}$ and $Y \neq X$ then $\exists a \in X \setminus Y$ s.t. $Y \cup \{a\} \in \mathcal{F}$.*

2.2 Convex Dimension

This section follows the survey on convex geometries [7].

Definition 2.5. *An alignment $\mathcal{F}$ is called a monotone alignment if the sets of $\mathcal{F}$ form a chain under the inclusion order.*

Definition 2.6. *Given two alignments $\mathcal{F}, \mathcal{K}$, their join $\mathcal{F} \vee \mathcal{K}$ is defined to be the smallest alignment that contains both $\mathcal{F}$ and $\mathcal{K}$. Explicitly, for alignments on finite set X, this is the collection of all intersections of sets taken from $\mathcal{F}, \mathcal{K}$: $\mathcal{F} \vee \mathcal{K} = \{F \cap K : F \in \mathcal{F} \text{ and } K \in \mathcal{K}\}$.*

A known result in Edelman and Jamison [7] about joins follows.

Theorem 2.1. *Every alignment can be expressed as the join of some collection of monotone alignments on the same base set.*

This motivates the following definition.

Definition 2.7. *The* convex dimension *of a convex geometry G is the least number k such that the alignment $\mathcal{F}$ corresponding to G can be expressed as the join of k monotone alignments.*

To compute the convex dimension of a convex geometry, we can examine antichains of meet-irreducibles.

Definition 2.8. *A* meet-irreducible *in an alignment $\mathcal{F}$ is a closed set $Y \in \mathcal{F}$ for which there exists $Z \in \mathcal{F}$ such that*

    1. $Y \subset Z$
    2. If $Y \subset W$, for some closed set W, then $Z \subseteq W$.

This is equivalent to saying that if $Y = \bigcap_{i \in I} Y_i$ where $Y_i \in \mathcal{F}$ for all i, then $Y = Y_i$ for some $i \in I$.

Note that by definition 2.4 of a convex geometry, we can additionally claim that $|Z \setminus Y| = 1$.

Definition 2.9. *In a partially ordered set, an* antichain *is a collection of pairwise non-comparable elements.*

Set inclusion forms a partial order on the elements of an alignment, and this partial order allows us to talk about antichains of elements of an alignment. The following result is due to Edelman and Saks [8].

Theorem 2.2. *Let G be a convex geometry and $\mathcal{F}$ be the corresponding alignment. The convex dimension of G is equal to the largest size antichain of meet-irreducibles.*

2.3 Convex hull operator

A particular example of a closure operator on a set is the convex hull operator, where the base set X is a set of points in Euclidean space $\mathbb{R}^n$. For the goals of this paper we use only the plane, i.e. space $\mathbb{R}^2$.

Definition 2.10. *A set S in $\mathbb{R}^2$ is called a* convex set *if for any two points $p, q \in S$, the line segment connecting p and q is also contained in S.*

See Figure 1 for illustration.
Figure 1: Example of a set which is convex and a set which is not convex.

Definition 2.11. *Given a set S of points in $\mathbb{R}^2$, the convex hull of S, in notation* CH(S)*, is the intersection of all convex sets in $\mathbb{R}^2$ which contain S.*

From the illustration, if $S = \{A, B, C, D, E, F, G\}$, a set of of 7 points on the plane, CH(S) is a convex shape with vertices A, C, D, F, G on Figure 2.
Figure 2: The convex hull CH$(ABCDEFG)$

The following definition allows us to introduce a closure operator induced by the convex hull, on any set of points X on the plane.

Definition 2.12. *Let X be a finite set of points in $\mathbb{R}^2$. Define operator* ch : $2^X \to 2^X$ *as follows:*

$$\mathrm{ch}(Y) = \mathrm{CH}(Y) \cap X,$$

for any $Y \in 2^X$.

It is straightforward to check that ch is a closure operator. For example, ch$(ACDFG) = S$ from Example on Figure 2. Moreover, ch satisfies the Anti-Exchange Property. Therefore, (X, ch) is a convex geometry.

Finally, for the purposes of the current paper we want to recall the definition of the convex hull operator for circles introduced in Cédli [6].

If x is a circle on the plane, then by $\tilde{x}$ we denote a set of points belonging to x. We allow a circle to have a radius 0, thus, a point is a circle that includes a single point.

Definition 2.13. *Let X be a finite set of circles in $\mathbb{R}^2$. Define operator* ch$_c$: $2^X \to 2^X$*, a convex hull operator for circles, as follows:*

$$\mathrm{ch}_c(Y) = \{x \in X : \tilde{x} \subseteq \mathrm{CH}(\bigcup_{y \in Y} \tilde{y})\},$$

for any $Y \in 2^X$.

For example, $a, e \in \mathrm{ch}_c(b, c, d)$ on Figure 3a, while $a \notin \mathrm{ch}_c(b, c, d)$, $e \in \mathrm{ch}_c(b, c, d)$ in Figure 3b.
(a) Circle a is in the convex hull of b, c, d

(b) Circle a is not in the convex hull of b, c, d

3   Creating the list of geometries on 4- and 5-element sets

An OEIS (On-line Encyclopedia of Integer Sequences) submission on the number of non-isomorphic antimatroids by Przemysław Uznański [10] served as the starting point for our project. From a combinatorial point of view, a family $\mathcal{F}$ of subsets of (finite) X is called an *antimatroid* if and only if:

1. $\mathcal{F}$ is closed under unions, i.e. $\forall Z, Y \in \mathcal{F}, Z \cup Y \in \mathcal{F}$

2. $\mathcal{F}$ is non-empty accessible, i.e $\forall Y \in \mathcal{F}$ either $Y = \emptyset$ or $\exists\, x \in Y$ such that $Y \setminus x \in \mathcal{F}$.

A close look at the properties reveals that there exists a bijective map f, between antimatroids and convex geometries given by:

$$f(\mathcal{F}) = \{Y^c \colon Y \in \mathcal{F}\} \tag{1}$$

Here $Y^c = X \setminus Y$, a set-theoretical complement of subset $Y \subseteq X$.

Uznański in [10] generated a list of all non-isomorphic antimatroids on base sets of order 3, 4, 5 and 6 using an extension property on antimatroids combined with a reverse tree traversal algorithm. The theoretical background of the algorithm was developed in Kempner and Levit [9].

Adapting Uznański's original codebase, all convex geometries can be easily generated using the bijection noted above. The antimatroids and their corresponding geometries are represented as elements of 2^{2^X} using their associated alignments as described by Definition 2.3. For efficiency and portability however, the alignments are physically stored, and listed in the Appendices A, as 32-bit integers through a programming technique known as *bitmasking* [12].

Given a 32-bit representation $b_{31} b_{30} \ldots b_1 b_0$ and $X = \{x_1 \ldots x_n\}$ where $n = 3, 4, 5$, one may obtain the convex sets, F, by writing $S = \{i \,:\; b_i = 1\}$. The convex sets shall then be given by

$$F_k = \{x_i \; : \; c_i = 1, \; c_5 \ldots c_1 = S_k \in S\} \tag{2}$$

where c_i are the bits of S_k.

Example 1.

For a base set of order 3, represented as $\{a, b, c\}$, assign the zeroth, first and second bits to a, b and c respectively. Then $\{a\}$ is represented as $001(1)$, $\{b\}$ is represented as $010(2)$, $\{a, b, c\}$ is represented as $111(7)$, $\emptyset$ as $000(0)$ and so on. . . It is easy to check that the decimal equivalents of the binary representation of subsets form the set $\{0, 1, 2 \ldots 2^n - 1\}$ where n is the order of the base set. A family F has its nth bit set (value 1), if and only if the subset is represented by $n \in F$.

Example 2.

For example, for a base set of order 3, the family $F = \{\emptyset, \{a\}, \{a, b\}, \{a, b, c\}\}$ is represented as $10001011(139)$ because $\emptyset \to 0, \{a\} \to 1, \{a, b\} \to 3, \{a, b, c\} \to 7$, and hence the zeroth, first, third and seventh bits are set.

A useful perspective on a convex geometry is provided by its *implications*. Given a convex geometry $(X, \mathcal{F})$, $A \to B$, where $A, B \in 2^X$, is an implication if and only if:

$$B \subseteq \varphi(A) = \bigcap \{Y \colon A \subseteq Y, \; Y \in F\} \tag{3}$$

where φ is the closure operator associated with $(X, \mathcal{F})$ as defined in Definition 2.1. A set of implications fully defining closure operator φ is often referred to as *implicational basis* of a closure system. The recent exposition on implicational bases is given in Adaricheva and J.B.Nation [4].

Because implications are very useful for representing geometries, they were generated for each geometry in addition to its convex sets. However, some implications are redundant with respect to others. For example, $ab \to c$ is redundant if $a \to c$. Hence work was also done in attempt to remove such redundancies.

In practice we only removed pairwise redundancies, but an *optimum* implication list could be found using a brute force approach (in general the problem of finding such an optimum implication list is NP-hard, see [5, 11]). The pairwise reduction was achieved by declaring implication $A \to B$ redundant if there exists an implication $C \to D$ such that $C \subseteq A$ and $B \subseteq D$.

To obtain a list of only convex geometries with convex dimension less than or equal to 5, as per Problem 1 in [1], calculation of each geometry's dimension was also necessary. As described in Section 2.2, one may compute convex dimension by starting with the meet-irreducible convex sets, which can be identified by the convex sets Y that have only one convex superset Z such that $|Z \setminus Y| = 1$. From there, one can build a maximal antichain of said irreducibles using recursive techniques. And by Theorem 2.2, the convex dimension is the cardinality of this maximal antichain.

4 Conquering the list

Once we had a complete list of geometries on 4- and 5-element sets, we began working on finding representations for them. The 34 4-element convex geometries helped us all gain some intuition and practice; some of us represented (or even came up without looking at the list) all 34 independently, while others represented the easier ones first and then worked together on harder representations. As the list was only 34 geometries, this work took no longer than a week. The work was posted and discussed on the social site Discord, and images were tagged with spoilers so that we all had a chance to try problems in order to practice our visual problem solving.

In contrast, the list of 672 5-element geometries needed much more time and organization. Each team member was initially assigned 10 geometries, and since it was already known that at least some convex geometries of dimension 6 could not be represented by circles and points [1], we were only assigned convex geometries of dimension less than 6 and left those of dimension 6 for later analysis. After a representation was made by one team member and before it was added to the final paper, it was posted to Discord where another team member would check it. We used a spreadsheet, originally organized by team member but later also organized by geometry number, to keep track of who was representing each geometry, who had checked it, and whether it had been added into the final file.

In the first week of working on the 5-set geometries, we realized some geometries resisted attempts at representation by circles and points. One Team member started the discussion by posting a geometry they could not represent, and other Team members also began asking each other to check difficult geometries.

At the next group meeting it was agreed that there seemed to be convex geometries of dimension less than 6 that could not be represented by circles and points, and a list was started to keep track of difficult convex geometries. Some Team members were able to represent the more difficult convex geometries, but some geometries stayed on the "Impossible Problems" list.

Some team members who had encountered such suspected impossible problems had several meetings where they examined these problems closely and began trying to articulate why they were not representable and formulate precise hypotheses. These efforts, and additional individual work, led to more formal conjectures and proofs of the impossibility of certain geometries.

Meanwhile, we continued working through the list by self-assigning geometries beyond our original assignment. Some students focused on one 5-element geometry at a time, while others worked on larger "chunks" by using various strategies to obtain 5-element geometry representations from representations of the 4-element convex geometries. As the list of represented geometries grew, so did the list of geometries we believed were impossible to represent.

Our final list of "Impossible" geometries came up with 51 cases. It is interesting to point out that majority of cases occurred within the first 100 geometries on the list of 672. The list of 672 is ordered by decreasing number of convex

sets in alignment, thus, geometries with more convex sets tend to have greater probability to appear on the list of "Impossible".

5 Representation of geometries on 5-element set based on representations on 4-element or 3-element set

In addition to building our intuition, creating representations for the 34 order 4 convex geometries served another purpose in that several "chunks" of representations of geometries on a 5-element base set could be generated from these 4-element representations simply by strategically adding another circle.

The first chunk of representations we generated were for those geometries with a unique atom (a, b, c, d, or e). To do this, we modified the representation on a 4-element base set so that all of the circles a, b, c, and d had a nontrivial intersection and then placed a point e in this intersection so that it would be in the convex hull of any other circle, adding the implications $a \rightarrow e$, $b \rightarrow e$, $c \rightarrow e$, and $d \rightarrow e$ to those of the previous 4-element geometry. This generated 34 previously unrepresented convex geometries on a base set of order 5 that were later identified, using a list of 5-element convex geometries with a unique atom generated by a coded search function, and added to the main collection of representations for 5-element geometries.

The next chunk of geometries we represented were those with a unique coatom ($abcd, abce, abde$, or $bcde$). To do this, we kept the representation of the 4-element convex geometry and simply added a fifth circle e that contained all of the other circles, adding the implication $e \rightarrow abcd$ to the previous list of implications for the 4-element geometry. This generated another 28 previously unrepresented geometries that were later identified and added to the master list in the same way as the first group.

Next we represented a chunk of geometries on a 5-element base set by essentially doubling a circle representing an element that was on the left side of all of its implications. To do this, we made a copy e of the circle as close to the original circle as possible, so as not to add any unwanted implications. This added copies of each implication that had previously involved the original circle but with e substituting for the element represented by the original circle in each implication. Sometimes only one circle could be duplicated in this way per geometry, but other times multiple circles could be doubled, allowing us to generate multiple 5-element representations from a single 4-element representation. Because there was not an easy way to code a search for the new geometries we had represented, it was necessary to identify them manually by scanning through the 5-element list.

The final chunk of order 5 representations we generated from those of order 4 were created by placing a fifth element e in one of the other four elements. This was inspired by an observation that after a certain point in our project, almost all of the remaining geometries included binary implications (of the form

$x \to y$). We tried to generate implications in as many different ways as we could by placing this fifth element within one of the other four while also avoiding duplicating a geometry in one of the chunks we had already generated. This allowed us to generate several order 5 representations from a single order 4 representation, although some were isomorphic to each other and others were isomorphic to existing representations. We identified these using an automated search program for geometries isomorphic to the one given.

An additional chunk of 5-element geometries could be represented based on representations on a base set of order 3, of which there are only 6. Each of these 6 representations could generate 2 unique 5-element representations, one by creating a non-trivial intersection between the 3 elements and then placing two new elements d and e in the middle, and one by keeping the 3-element representation the same and enclosing it in two large overlapping circles d and e. These newly generated representations were identified using a coded search function and added to the master list of representations for geometries on a base set of order 5.

6   Checking correctness of representations

Originally, the method for checking the correctness of representations required a tedious procedure of making sure that a circle representation satisfied all implications of its associated convex geometry, and no additional implications were forced by the configuration of any two, three, or four circles of the representation. Eventually we came up with a simplified procedure based on statements that would imply the isomorphism of two geometries.

We recall from section 3 that the closure operator φ can be recorded in the set Σ of implications, where $Y \to Z$ means $Z \subseteq \varphi(Y)$. Then the corresponding alignment of φ-closed sets comprises all subsets of X that *respect* all implications in Σ: if $(Y \to Z) \in \Sigma$ and $Y \subseteq W$ for set W in alignment, this would imply $Z \subseteq W$.

A discussion of the nature of our representations by circles is necessary here to further explain the reasoning behind our checking method. Convex geometries on our list were given by both an alignment $\mathcal{F}$ on set X and a set of implications Σ. In order to produce a representation by circles, each element of X was represented by a circle, and the positioning of circles in the plane would define a closure operator ch_c, the convex hull operator for circles. A geometry generated by these circles would be isomorphic to $(X, \mathcal{F})$ if the alignments match, i.e. if the alignment $\mathcal{G}$ generated by ch_c consists of the same subsets as $\mathcal{F}$. The following two statements formed the basis for such matching.

Proposition 6.1. *Let $(X, \mathcal{F})$ be an alignment defined by a set of implications Σ. Let ψ be any closure operator defined on X and the corresponding alignment of ψ-closed sets be $\mathcal{G}$. If for every $(Y \to Z) \in \Sigma$ one has $Z \subseteq \psi(Y)$, then $\mathcal{G} \subseteq \mathcal{F}$.*

Proof. Indeed, take any set $W \in \mathcal{G}$. We need to show that $W \in \mathcal{F}$, i.e., it respects all implications from Σ. So take $Y \to Z$ in Σ and let $Y \subseteq W$. Since

by assumption we have $Z \subseteq \psi(Y)$, and W is ψ-closed, we have $Z \subseteq W$ as desired. □

In the practical procedure of checking representation, we would check whether for any implication $Y \to Z$ from the set of implications defining the given convex geometry, all circles in Z are in the convex hull of circles from Y.

Proposition 6.2. *If all meet-irreducible sets from alignment $\mathcal{F}$ belong to $\mathcal{G}$, then $\mathcal{F} \subseteq \mathcal{G}$.*

Proof. Indeed, every set in $\mathcal{F}$ is the intersection of meet-irreducible sets. Therefore, they all belong to $\mathcal{G}$. □

In practice, we would check that all circles belonging to the meet-irreducible set of a given convex geometry form a convex set of circles. Combining the two practical procedures following from the propositions above, we could conclude that the given convex geometry is isomorphic to our convex geometry of circles.

7   GeoGebra as a toolkit for representations

At the beginning of this project, creating a representation for a geometry entailed drawing out the circles by hand, and then manually representing the drawing on Overleaf, the Latex processing website. One had to take care to preserve the convex hulls as precisely as possible and not generate unwanted implications.

This became especially cumbersome on certain geometries that were possible but required a very precarious setup, where even the slightest shift in the position of a circle would make the representation incorrect. A few weeks into the project, several team members highlighted the usefulness of GeoGebra as a tool for representing Geometries, which allowed for the easy rearrangement of circles and points to one's liking. Eventually a Team member came up with a template GeoGebra file [13] that allowed users to adjust not only the position and radii of the circles, but also to draw the convex hulls of all possible combinations of circles. This made it easier to check if a representation was actually correct or not.

Using GeoGebra helped in checking if a representation of a geometry was correct, but once represented, they still had to be remade in LaTeXusing the TikZ package. It was soon discovered that GeoGebra had a built in way to export images to TikZ code, but this code was improved upon by members of our team to generate the desired representation.

8   Google Colab toolkit

In order to streamline the process of exporting representations of geometries to Overleaf, a few team members worked to make a Python script to automatically generate TikZ code to paste into Overleaf. GeoGebra already had a feature that

allowed this, but the generated code had unnecessary elements that needed to be deleted, making the process less than optimal.

Midway through the project, a Team member wrote a Python script where the user would input the centers and radii of each circle, and the program would generate TikZ code that was readily available to be pasted into Overleaf. The centers and radii of the circles were shown in GeoGebra, so the user only had to copy those numbers into the script.

Simultaneously, another Team member had created a script in a Google Colab notebook that would parse through the TikZ code generated by GeoGebra, extract all of the necessary information (such as circle location and radii) and then output useable TikZ code. This new code, however, had issues with normalizing the size of the circles to fit nicely on the page, and so features of both scripts were combined in the Google Colab notebook. The end result was code that would accept a text file from GeoGebra and reliably output useable TikZ code for the Overleaf [14].

9 Triangle Property and Impossible geometries

In this section we will be proving that several geometries on a 5 element set are not representable by circles on the plane.

9.1 Tight implication on circles

The following statement is a modification of Lemma 5.1 in [1].

Lemma 1. *Let a, b, c be three circles on the plane. Then there are four different types of configurations of three circles a, b, c:*

(1) $x \in \mathrm{ch}_c(y, z)$, $\{x, y, z\} = \{a, b, c\}$;

(2) $\mathrm{ch}_c(x, y, z) = \mathrm{ch}_c(x, y) \cup \mathrm{ch}_c(y, z)$ *as in Figure 4 with $a = x$, $y = b$, $z = c$ or in Figure 5 with $b = x$, $c = y$, $a = z$.*

(3) $\mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c})$ *is inscribed into a triangle as in Figure 6;*

(4) $\mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c})$ *forms a shape as in Figure 7.*
Figure 4
Figure 5
Figure 6

Figure 7

Proof. The argument can be corroborated by Lemma 4 that describes all possible borders of the convex hull of three circles.

Case (1) is distinguished from others by the property $\mathrm{ch}_c(x,y,z) = \mathrm{ch}_c(y,z)$.

In case (2) one of the circles crosses both outer tangent lines of two other circles and has two points of intersection with at least one of those outer tangents.

Case (4) is similar to (3), but it is distinguished by having an arc larger than π from one of the circles as a part of the border of $\mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c})$. $\qquad\square$

Definition 9.1. *An implication* $Y \to u$, $Y \subseteq X, u \in X$, *is called* tight, *if implications* $(Y \setminus z) \to u$ *do not hold, for all* $z \in Y$.

Lemma 2. *For an implication* $Y \to u$, $Y \subseteq X, u \in X$, *if there exists* $y \in Y$ *such that* $(Y \setminus y) \to y$, *then implication* $Y \to u$ *cannot be tight.*

Proof. Let φ be the closure operator. If there exists $y \in Y$ such that $(Y \setminus y) \to y$, then $y \in \varphi((Y \setminus y))$. Also since for any A, $A \subseteq \varphi(A)$, we have $Y \subseteq \varphi((Y \setminus y))$. Now applying the closure operator to both sides, $\varphi(Y) \subseteq \varphi((Y \setminus y))$, as $\varphi(\varphi(A)) = \varphi(A)$. Since $Y \to u$, $u \in \varphi(Y)$ and $u \in \varphi((Y \setminus y))$. Thus $(Y \setminus y) \to u$, and hence $Y \to u$ cannot be tight. $\qquad\square$

Lemma 3. *If* $abc \to d$ *is any tight implication that holds for circles* a, b, c, d, *then* a, b, c *cannot form a configuration in (1) or (2) of Lemma 1, for any assignment of* x, y, z *to* a, b, c.

Proof. Indeed, if a, b, c form a configuration in (1), then the implication $abc \to d$ cannot be tight due to Lemma 2. For configuration (2) where $\mathrm{CH}(\tilde{x} \cup \tilde{y} \cup \tilde{z}) = \mathrm{CH}(\tilde{x} \cup \tilde{y}) \cup \mathrm{CH}(\tilde{y} \cup \tilde{z})$, we note that for any circle d in $\mathrm{ch}_c(x, y, z)$ we have either $d \in \mathrm{ch}_c(x, y)$ or $d \in \mathrm{ch}_c(y, z)$. Note that the same may not be true for a shape d different from circle. $\qquad\square$

Lemma 4. *The border of* $\mathrm{CH}(\tilde{x} \cup \tilde{y} \cup \tilde{z})$ *for any three circles* a, b, c *comprises*

(I) two tangent segments and two arcs of circles, when configuration (1) from Lemma 1 occurs;

(II) four tangent segments and four arcs, as in Figure 4, for configurations in (2) from Lemma 1;

(III) three tangent segments and three arcs, as in Figure 6 and Figure 7, for configurations in (3) and (4) from Lemma 1.

15

Corollary 9.1. *If $abc \to e$ is any tight implication that holds for circles a, b, c, e, then the border of $\mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c})$ comprises three tangent segments and three arcs.*

9.2   Triangle Property

Given that the statement of Lemma 5 below is rather straightforward and its proof is elementary, we assume it is a part of mathematical folklore.
Figure 8: Triangle Property

Lemma 5 (The Triangle Property). *If a, b, c, and e are circles in the plane with centers A, B, C, and E respectively, and $abc \to e$ is a tight implication, then E must lie in the interior of triangle formed by A, B and C.*

Proof. If implication $abc \to e$ is tight, then by Lemma 3 circles a, b, c cannot form any configuration from (1) and (2) of Lemma 1.

Moreover, since $abc \to e$ is tight, the centers of a, b, c cannot be on a line, because, in that case one obtains one of configurations (1) or (2) in Lemma 1. Therefore, the centers form a triangle.

By Corollary 9.1, the border of $\mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c})$ comprises three tangent segments and three arcs, as in Figure 8. The convex hull of three circles a, b, c splits into two parts:

(I) the interior $int(\triangle ABC)$ of triangle formed by the centers of the circles;

(II) the shape $S = \mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c}) \setminus int(\triangle ABC)$.

Moreover, S splits into the union of the following shapes:

(I) trapezoids formed between pairs of circles, each of which includes a segment connecting the centers of the two circles, two radii, and the circles' common tangent segment;

(II) sectors of circles bordered by the radii which are the borders of trapezoids from (I).

16

If circle e is inside of the convex hull of a, b, c, and its center E is not in the interior of $\triangle ABC$, then it is in S. Thus it is either in one of the trapezoids or in one of the sectors.

Without loss of generality, suppose that E is inside of one of sectors of circle a. Then the distance σ from E to the border of circle is $\leq r_a$. Therefore, $r_e \leq r_a$ and $e \in \mathrm{ch}_c(a)$.

Suppose now that E is in one of the trapezoids. Without loss of generality, suppose that E is in $BCGF$ in Figure 8, where FG is the part of the border of $\mathrm{CH}(\tilde{a} \cup \tilde{b} \cup \tilde{c})$, and σ is the distance from E to segment FG. Then $r_e \leq \sigma$ and $e \in \mathrm{ch}_c(b, c)$ thusly.

Therefore, the center of e for which $abc \to e$ is tight cannot be in either the trapezoids or sectors, and thus it must be in interior of $\triangle ABC$. $\qquad \square$

The following statement is a generalization of the Triangle Property.

Corollary 9.2. *If $n > 2$, $a_1, a_2, a_3, \cdots, a_n, d$ are circles in the plane with centers $C_1, C_2, \cdots, C_n, D$ respectively, and $a_1 a_2 a_3 \cdots a_n \to d$ is tight then $D \in \mathrm{CH}(C_1, C_2, \cdots, C_n)$.*

Proof. Let $S = \mathrm{CH}(\tilde{a_1} \cup \tilde{a_2} \cup \cdot \cup \tilde{a_n})$ and let $S' = \mathrm{CH}(C_1, C_2, \cdots, C_n)$. Obviously, D, as well as every other point in $\mathrm{CH}(d)$, must be contained wholly within S in order for the implication $a_1 a_2 a_3 \cdots a_n \to d$ to hold. Since $n > 2$, the centers of the circles cannot all be colinear as this would force every subset of three circles into configuration (1) or (2) as in Lemma 1.

The boundary of S consists of a cyclic sequence of circles connected by mutual tangents. If a_i and a_j, for $i, j \in \{1, 2, \cdots, n\}$, are consecutive circles along the boundary of S then let ℓ be the line connecting C_i to C_j. The line ℓ divides the plane into two half-planes, we define $H_{i,j}$ to be the outward facing half-plane, that is, it is the half plane that does not contain S'. The set of points in $S \cap H_{i,j}$ can be split as the union of three regions,

(I) A trapezoidal region which includes a segment connecting C_i to C_j, the mutual tangent segment connecting a_i to a_j on the boundary of S, and two radii of a_i and a_j connecting to endpoints of the mutual tangent.

(II) The sectors of the circles a_i and a_j in $H_{i,j}$ but outside of the trapezoid described in (I).

If $D \in S \setminus S'$, then D must be in one of the half-planes associated to a pair of consecutive circles on the boundary of S. Suppose that $D \in H_{i,j}$.

If D is inside one of the sectors of circle a_i (without loss of generality), let δ be the distance between the circumference of d and the point x on the circumference of a_i which is closest to d. If the radius of d is less than or equal to δ then $d \subseteq \mathrm{CH}(c)$, which violates the assumption that $a_1 a_2 a_3 \cdots a_n \to d$ is a tight implication, and thus the the radius of d must be greater than δ. A ray, r, centered at C_i which passes through D will intersect a_i at the point x which is closest to D. Since C_i is on ℓ and D is in $H_{i,j}$, every point on r is in $H_{i,j}$, furthermore, since D is not inside the trapezoid described in (I), every

point on on the ray r beyond x must be outside of S. Hence, if the radius of d is greater than δ then $\mathrm{CH}(\tilde{d})$ must contain some points outside of S implying $a_1 a_2 a_3 \cdots a_n \nrightarrow d$.

Now, suppose that D is inside the trapezoid described in (I). Let s_1 be the mutual outer tangent between a_i and a_j in $H_{i,j}$, let s_2 be the inner tangent, outside of $H_{i,j}$, and let δ be the distance between D and s_1. Because the two circles, a_i and a_j are symmetric about the line ℓ, the distance between ℓ and s_1 is equal to the distance between ℓ and s_2. Since $D \in H_{i,j}$, it follows that δ is less than or equal to the distance between D and s_2. If the radius of d is less than δ then d is contained entirely between s_1 and s_2 implying that $d \subseteq \mathrm{CH}(\tilde{a}_i \cup \tilde{a}_j)$, which violates the assumption that the implication $a_1 a_2 a_3 \cdots a_n \to d$ is tight. Alternatively, if the radius of d exceeds δ then, since s_1 is a boundary of S, $\mathrm{CH}(d)$ will contain at least one point not in S, implying $a_1 a_2 a_3 \cdots a_n \nrightarrow d$. □

Corollary 9.3. *Convex geometries representable by circles cannot have three tight implications $abc \to e$, $abd \to e$, $acd \to e$.*

Proof. Indeed, consider A, B, C, D, E, the centers of circles that might represent this geometry. Connect A with B, C and D. Then the plane splits into three angles at vertex A. Choose two of smallest angles among these three. Without loss of generality, assume that the smallest are $\angle CAB$ and $\angle BAD$. Then each of the two smallest angles are less than π, thus, line (AB) splits the plane into two semi-planes, so that C and D are in distinct semi-planes (see illustration in Figure 9).
Figure 9: Corollary 9.3

By Lemma 5, E must be in the interior of $\triangle ABC$ as well as in the interior of $\triangle ABD$, and since those interiors do not intersect, there is no possible location for E. □

This gives us six geometries on the list that are not representable: G7, G11, G12, G18, G21 and G34. Note that G7, G21 and G34 have cdim=4.

18

Corollary 9.4. *Convex geometries representable by circles cannot have three tight implications $abc \to d$, $acd \to e$, $bcd \to e$.*

Proof. Assume that the geometry does have a representation as a geometry of circles. The proof then follows from the use of Lemma 5 two times. First, since $abc \to d$ is a tight implication, D must lie in the interior of triangle formed by vertices A, B and C (which are the centers of a, b, c). Moreover, we have two tight implications $acd \to e$, $bcd \to e$. However, by Lemma 5 again, we would need E to be in the interior of both $\triangle ACD$ and $\triangle BCD$, which is not possible. $\square$

This gives us that the additional geometry G23 cannot be represented by circles on the plane.

Appendices

A

This appendix lists the output of the process described in §3, i.e., it lists every non-isomorphic convex geometry of sizes 4 and 5. The id tag represents the corresponding convex geometry's 32-bit integer representation as also described in §3.

B

This appendix includes the representations of all 34 size 4 geometries (§B.1) and 621 of 672 size 5 geometries (§B.2).

B.1 Representation of size 4 geometries

1

Boolean

2

$abc \rightarrow d$

3

$ab \rightarrow d$

4

$$ab \to d,\ ac \to d$$

5

$$ab \to cd$$

6

$$a \to d$$

7

$$ab \to d,\ ac \to d,\ bc \to d$$

8

$$ab \rightarrow cd, ac \rightarrow d$$

9

$$a \rightarrow d, bc \rightarrow d$$

10

$$a \rightarrow d, ab \rightarrow cd$$

11

$$ac \rightarrow d, \ bc \rightarrow d, \ ab \rightarrow cd$$

12

$$ad \to c,\ bc \to d,\ ab \to cd$$

13

$$a \to d,\ b \to d$$

14

$$a \to d, bc \to d, ab \to cd$$

15

$$a \to cd$$

177

16

$$a \to c, bc \to d, ab \to cd$$

17

$$c \to d, ab \to cd$$

18

$$a \to d, b \to d, c \to d$$

19

$$a \to d, b \to d, ab \to cd$$

20

$$a \to c,\ b \to d$$

21

$$a \to d,\ c \to d,\ ab \to cd$$

22

$$a \to cd,\ bc \to d$$

23

$$a \to bcd$$

24

$$a \to d,\ b \to d,\ c \to d,\ ab \to cd$$

25

$$a \rightarrow cd,\ b \rightarrow d$$

26

$$a \rightarrow cd,\ c \rightarrow d$$

27

$$a \to bcd, \, bc \to d$$

28

$$a \to cd, \, c \to d, \, b \to d$$

29

$b \to cd,\ a \to cd$

30

$b \to d,\ a \to bcd$

31

$a \to cd,\ c \to d,\ b \to cd$

32

$a \to bcd,\ c \to d,\ b \to d$
33
$$b \to cd,\ a \to bcd$$

34
$$c \to d,\ b \to cd,\ a \to bcd$$

B.3   Impossible Geometries

```
4. Weak Carousel Rule
abc -> de
dimension: 6

7. Triangle Property
acd -> e
abd -> e
abc -> e
dimension: 4

11. Triangle Property
bcd -> e
acd -> e
abd -> e
abc -> e
dimension: 6

12. Triangle Property
acd -> e
abd -> e
abc -> de
dimension: 5

14.
bcd -> e
acd -> e
ab -> e
dimension: 5

15.
acd -> e
abc -> de
ab -> e
dimension: 5

18. Triangle Property
bcd -> e
acd -> e
abd -> e
abc -> de
dimension: 6

21. Triangle Property
abe -> d
```

```
bcd -> e
acd -> e
abc -> de
dimension: 4

23. Triangle Property Corollary
bcd -> e
acd -> e
abc -> de
ab -> e
dimension: 6

26.
bcd -> e
ad -> e
abc -> de
dimension: 5

27.
abe -> d
bcd -> e
abc -> de
ac -> e
dimension: 4

33.
abc -> de
ac -> e
ab -> e
dimension: 5

34. Triangle Property
bcd -> e
acd -> e
abc -> de
ab -> d
dimension: 4

35.
bcd -> e
ad -> e
abc -> de
ab -> e
dimension: 5

39.
```

```
bcd -> e
acd -> e
ab -> de
dimension: 5

43.
ace -> d
bcd -> e
ab -> de
dimension: 4

45.
ad -> e
abc -> de
bc -> e
dimension: 5

46.
bcd -> e
ad -> e
ac -> e
ab -> e
dimension: 4

47.
abe -> d
abc -> de
bc -> e
ac -> e
dimension: 4

49.
bcd -> e
abc -> de
ac -> e
ab -> e
dimension: 6

54.
bcd -> e
acd -> e
ab -> cde
dimension: 5

56.
ad -> e
```

```
abc -> de
bc -> e
ab -> e
