The Number of Intersection Points Made by the Diagonals of a Regular Polygon

Bjorn Poonen, Michael Rubinstein

Abstract. We give a formula for the number of interior intersection points made by the diagonals of a regular n-gon. The answer is a polynomial on each residue class modulo 2520. We also compute the number of regions formed by the diagonals, by using Euler's formula $V - E + F = 2$.

Key words. regular polygons, diagonals, intersection points, roots of unity, adventitious quadrangles

THE NUMBER OF INTERSECTION POINTS MADE BY THE DIAGONALS OF A REGULAR POLYGON

BJORN POONEN AND MICHAEL RUBINSTEIN

ABSTRACT. We give a formula for the number of interior intersection points made by the diagonals of a regular n-gon. The answer is a polynomial on each residue class modulo 2520. We also compute the number of regions formed by the diagonals, by using Euler's formula $V - E + F = 2$.

1. INTRODUCTION

We will find a formula for the number $I(n)$ of intersection points formed inside a regular n-gon by its diagonals. The case $n = 30$ is depicted in Figure 1. For a *generic* convex n-gon, the answer would be $\binom{n}{4}$, because every four vertices would be the endpoints of a unique pair of intersecting diagonals. But $I(n)$ can be less, because in a regular n-gon it may happen that three or more diagonals meet at an interior point, and then some of the $\binom{n}{4}$ intersection points will coincide. In fact, if n is even and at least 6, $I(n)$ will always be less than $\binom{n}{4}$, because there will be $n/2 \geq 3$ diagonals meeting at the center point. It will result from our analysis that for $n > 4$, the maximum number of diagonals of the regular n-gon that meet at a point other than the center is

2 if n is odd,
3 if n is even but not divisible by 6,
5 if n is divisible by 6 but not 30, and,
7 if n is divisible by 30.

with two exceptions: this number is 2 if $n = 6$, and 4 if $n = 12$. In particular, it is impossible to have 8 or more diagonals of a regular n-gon meeting at a point other than the center. Also, by our earlier remarks, the fact that no three diagonals meet when n is odd will imply that $I(n) = \binom{n}{4}$ for odd n.

A careful analysis of the possible configurations of three diagonals meeting will provide enough information to permit us in theory to deduce a formula for $I(n)$. But because the explicit description of these configurations is so complex, our strategy will be instead to use this information to deduce only the *form* of the answer, and then to compute the answer for enough small n that we can determine the result precisely. The computations are done in Mathematica, Maple and C, and annotated source codes can be obtained via anonymous ftp at `http://math.berkeley.edu/~poonen`.

Date: November 18, 1997.

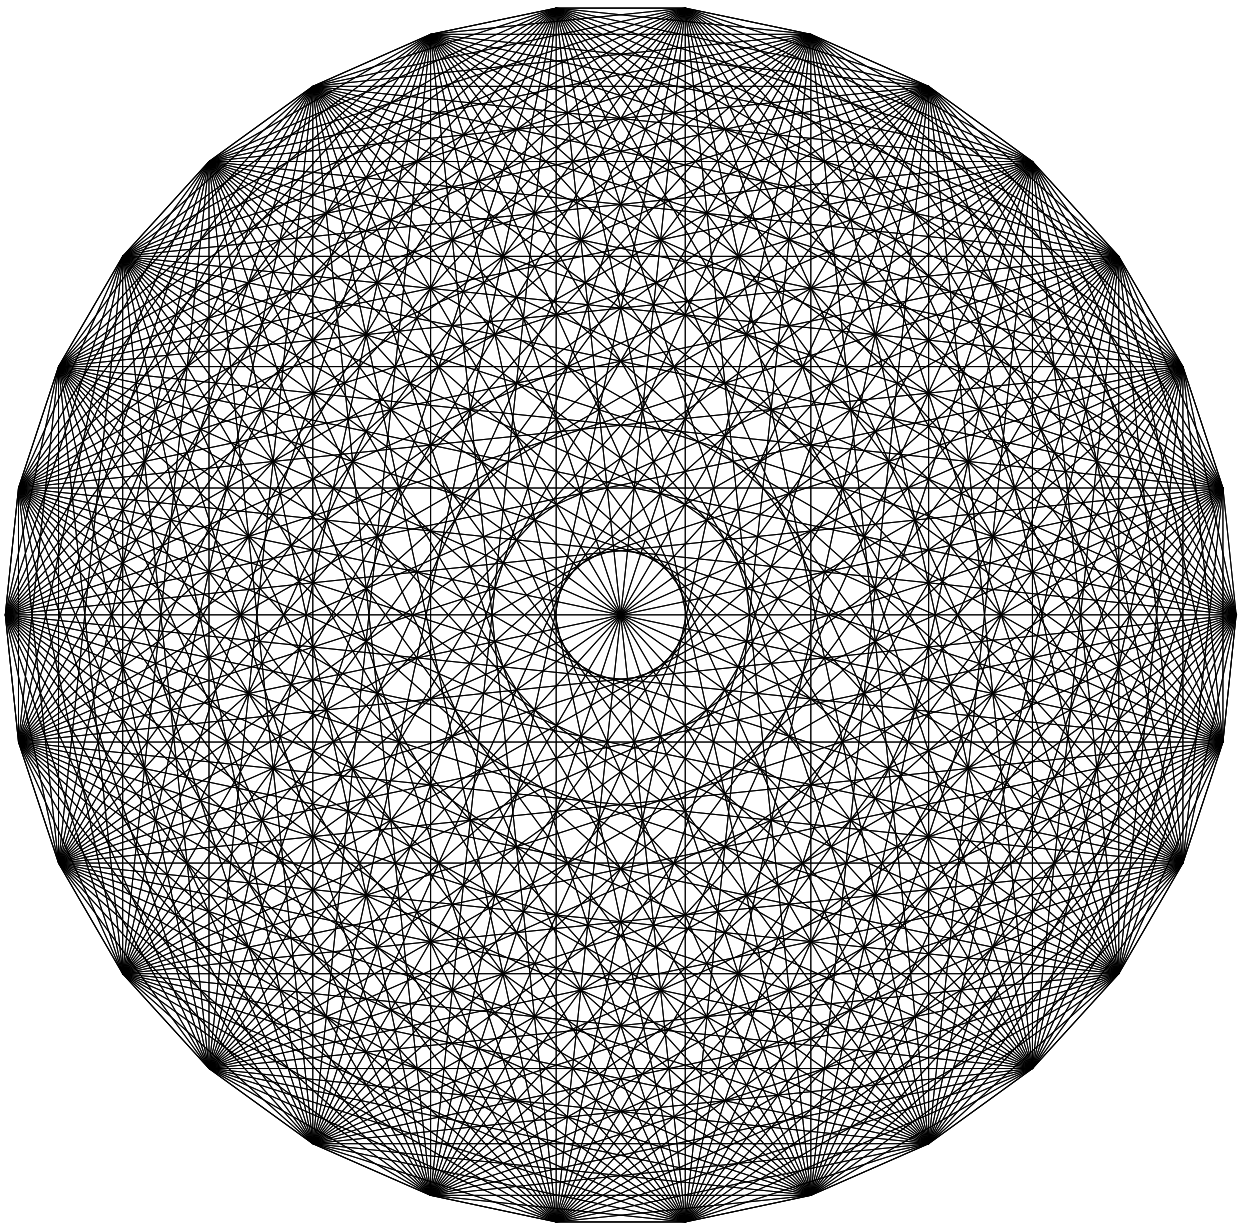

FIGURE 1. The 30-gon with its diagonals. There are 16801 interior intersection points: 13800 two line intersections, 2250 three line intersections, 420 four line intersections, 180 five line intersections, 120 six line intersections, 30 seven line intersections, and 1 fifteen line intersection.

In order to write the answer in a reasonable form, we define

$$\delta_m(n) = \begin{cases} 1 & \text{if } n \equiv 0 \pmod{m}, \\ 0 & \text{otherwise.} \end{cases}$$

Theorem 1. *For $n \geq 3$,*

$$\begin{aligned} I(n) &= \binom{n}{4} + (-5n^3 + 45n^2 - 70n + 24)/24 \cdot \delta_2(n) - (3n/2) \cdot \delta_4(n) \\ &\quad + (-45n^2 + 262n)/6 \cdot \delta_6(n) + 42n \cdot \delta_{12}(n) + 60n \cdot \delta_{18}(n) \\ &\quad + 35n \cdot \delta_{24}(n) - 38n \cdot \delta_{30}(n) - 82n \cdot \delta_{42}(n) - 330n \cdot \delta_{60}(n) \\ &\quad - 144n \cdot \delta_{84}(n) - 96n \cdot \delta_{90}(n) - 144n \cdot \delta_{120}(n) - 96n \cdot \delta_{210}(n). \end{aligned}$$

Further analysis, involving Euler's formula $V - E + F = 2$, will yield a formula for the number $R(n)$ of regions that the diagonals cut the n-gon into.

Theorem 2. *For $n \geq 3$,*

$$\begin{aligned} R(n) &= (n^4 - 6n^3 + 23n^2 - 42n + 24)/24 \\ &\quad + (-5n^3 + 42n^2 - 40n - 48)/48 \cdot \delta_2(n) - (3n/4) \cdot \delta_4(n) \\ &\quad + (-53n^2 + 310n)/12 \cdot \delta_6(n) + (49n/2) \cdot \delta_{12}(n) + 32n \cdot \delta_{18}(n) \\ &\quad + 19n \cdot \delta_{24}(n) - 36n \cdot \delta_{30}(n) - 50n \cdot \delta_{42}(n) - 190n \cdot \delta_{60}(n) \\ &\quad - 78n \cdot \delta_{84}(n) - 48n \cdot \delta_{90}(n) - 78n \cdot \delta_{120}(n) - 48n \cdot \delta_{210}(n). \end{aligned}$$

These problems have been studied by many authors before, but this is apparently the first time the correct formulas have been obtained. The Dutch mathematician Gerrit Bol [1] gave a complete solution in 1936, except that a few of the coefficients in his formulas are wrong. (A few misprints and omissions in Bol's paper are mentioned in [11].)

The approaches used by us and Bol are similar in many ways. One difference (which is not too substantial) is that we work as much as possible with roots of unity whereas Bol tended to use more trigonometry (integer relations between sines of rational multiples of π). Also, we relegate much of the work to the computer, whereas Bol had to enumerate the many cases by hand. The task is so formidable that it is amazing to us that Bol was able to complete it, and at the same time not so surprising that it would contain a few errors!

Bol's work was largely forgotten. In fact, even we were not aware of his paper until after deriving the formulas ourselves. Many other authors in the interim solved special cases of the problem. Steinhaus [14] posed the problem of showing that no three diagonals meet internally when n is prime, and this was solved by Croft and Fowler [3]. (Steinhaus also mentions this in [13], which includes a picture of the 23-gon and its diagonals.) In the 1960s, Heineken [6] gave a delightful argument which generalized this to all odd n, and later he [7] and Harborth [4] independently enumerated all three-diagonal intersections for n not divisible by 6.

The classification of three-diagonal intersections also solves Colin Tripp's problem [15] of enumerating "adventitious quadrilaterals," those convex quadrilaterals for which the angles formed by sides and diagonals are all rational multiples of π. See Rigby's paper [11] or the summary [10] for details. Rigby, who was aware of Bol's work, mentions that Monsky and Pleasants also each independently classified all three-diagonal intersections of regular n-gons. Rigby's papers partially solve

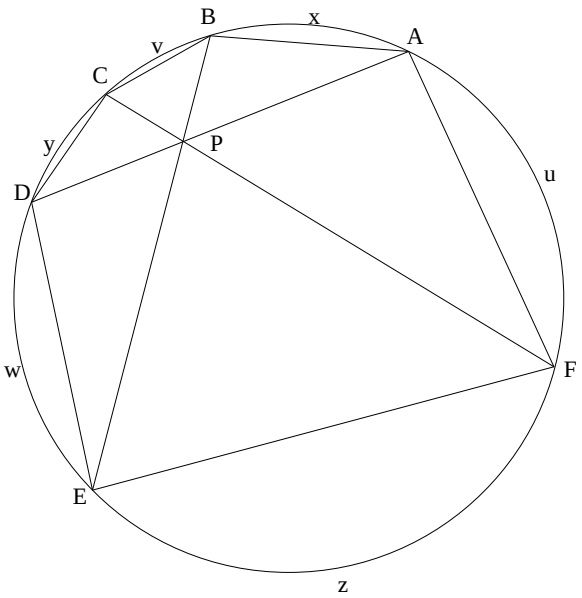

FIGURE 2.

Tripp's further problem of proving the existence of all adventitious quadrangles using only elementary geometry; i.e., without resorting to trigonometry.

All the questions so far have been in the Euclidean plane. What happens if we count the interior intersections made by the diagonals of a hyperbolic regular n-gon? The answers are exactly the same, as pointed out in [11], because if we use Beltrami's representation of points of the hyperbolic plane by points inside a circle in the Euclidean plane, we can assume that the center of the hyperbolic n-gon corresponds to the center of the circle, and then the hyperbolic n-gon with its diagonals looks in the model exactly like a Euclidean regular n-gon with its diagonals. It is equally easy to see that the answers will be the same in elliptic geometry.

2. When do three diagonals meet?

We now begin our derivations of the formulas for $I(n)$ and $R(n)$. The first step will be to find a criterion for the concurrency of three diagonals. Let A, B, C, D, E, F be six distinct points in order on a unit circle dividing up the circumference into arc lengths u, x, v, y, w, z and assume that the three chords AD, BE, CF meet at P (see Figure 2).

By similar triangles, $AF/CD = PF/PD$, $BC/EF = PB/PF$, $DE/AB = PD/PB$. Multiplying these together yields

$$(AF \cdot BC \cdot DE)/(CD \cdot EF \cdot AB) = 1,$$

and so

$$\sin(u/2)\sin(v/2)\sin(w/2) = \sin(x/2)\sin(y/2)\sin(z/2). \tag{1}$$

Conversely, suppose six distinct points A, B, C, D, E, F partition the circumference of a unit circle into arc lengths u, x, v, y, w, z and suppose that (1) holds. Then the three diagonals AD, BE, CF meet in a single point which we see as follows. Let lines AD and BE intersect at P_0 . Form the line through F and P_0 and let C' be the other intersection point of FP_0 with the circle. This partitions the circumference into arc lengths u, x, v', y', w, z. As shown above, we have

$$\sin(u/2)\sin(v'/2)\sin(w/2) = \sin(x/2)\sin(y'/2)\sin(z/2)$$

and since we are assuming that (1) holds for u, x, v, y, w, z we get

$$\frac{\sin(v'/2)}{\sin(y'/2)} = \frac{\sin(v/2)}{\sin(y/2)}.$$

Let $\alpha = v + y = v' + y'$. Substituting $v = \alpha - y$, $v' = \alpha - y'$ above we get

$$\frac{\sin(\alpha/2)\cos(y'/2) - \cos(\alpha/2)\sin(y'/2)}{\sin(y'/2)} = \frac{\sin(\alpha/2)\cos(y/2) - \cos(\alpha/2)\sin(y/2)}{\sin(y/2)}$$

and so

$$\cot(y'/2) = \cot(y/2).$$

Now $0 < \alpha/2 < \pi$, so $y = y'$ and hence $C = C'$. Thus, the three diagonals AD, BE, CF meet at a single point.

So (1) gives a necessary and sufficient condition (in terms of arc lengths) for the chords AD, BE, CF formed by six distinct points A, B, C, D, E, F on a unit circle to meet at a single point. In other words, to give an explicit answer to the question in the section title, we need to characterize the positive rational solutions to

$$\begin{aligned} \sin(\pi U)\sin(\pi V)\sin(\pi W) &= \sin(\pi X)\sin(\pi Y)\sin(\pi Z) \qquad (2)\\ U + V + W + X + Y + Z &= 1. \end{aligned}$$

(Here $U = u/(2\pi)$, etc.) This is a trigonometric diophantine equation in the sense of [2], where it is shown that in theory, there is a finite computation which reduces the solution of such equations to ordinary diophantine equations. The solutions to the analogous equation with only two sines on each side are listed in [9].

If in (2), we substitute $\sin(\theta) = (e^{i\theta} - e^{-i\theta})/(2i)$, multiply both sides by $(2i)^3$, and expand, we get a sum of eight terms on the left equalling a similar sum on the right, but two terms on the left cancel with two terms on the right since $U+V+W = 1-(X+Y+Z)$, leaving

$$-e^{i\pi(V+W-U)} + e^{-i\pi(V+W-U)} - e^{i\pi(W+U-V)} + e^{-i\pi(W+U-V)} - e^{i\pi(U+V-W)} + e^{-i\pi(U+V-W)} =$$
$$-e^{i\pi(Y+Z-X)} + e^{-i\pi(Y+Z-X)} - e^{i\pi(Z+X-Y)} + e^{-i\pi(Z+X-Y)} - e^{i\pi(X+Y-Z)} + e^{-i\pi(X+Y-Z)}.$$

If we move all terms to the left hand side, convert minus signs into $e^{-i\pi}$, multiply by $i = e^{i\pi/2}$, and let

$$\begin{aligned} \alpha_1 &= V + W - U - 1/2\\ \alpha_2 &= W + U - V - 1/2\\ \alpha_3 &= U + V - W - 1/2\\ \alpha_4 &= Y + Z - X + 1/2\\ \alpha_5 &= Z + X - Y + 1/2\\ \alpha_6 &= X + Y - Z + 1/2, \end{aligned}$$

we obtain

$$\sum_{j=1}^{6} e^{i\pi\alpha_j} + \sum_{j=1}^{6} e^{-i\pi\alpha_j} = 0, \tag{3}$$

in which $\sum_{j=1}^{6} \alpha_j = U+V+W+X+Y+Z = 1$. Conversely, given rational numbers $\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6$ (not necessarily positive) which sum to 1 and satisfy (3), we can recover U, V, W, X, Y, Z, (for example, $U = (\alpha_2 + \alpha_3)/2 + 1/2$), but we must check that they turn out positive.

3. Zero as a sum of 12 roots of unity

In order to enumerate the solutions to (2), we are led, as in the end of the last section, to classify the ways in which 12 roots of unity can sum to zero. More generally, we will study relations of the form

$$\sum_{i=1}^{k} a_i \eta_i = 0, \tag{4}$$

where the a_i are positive integers, and the η_i are distinct roots of unity. (These have been studied previously by Schoenberg [12], Mann [8], Conway and Jones [2], and others.) We call $w(S) = \sum_{i=1}^{k} a_i$ the *weight* of the relation S. (So we shall be particularly interested in relations of weight 12.) We shall say the relation (4) is *minimal* if it has no nontrivial subrelation; i.e., if

$$\sum_{i=1}^{k} b_i \eta_i = 0, \quad a_i \geq b_i \geq 0$$

implies either $b_i = a_i$ for all i or $b_i = 0$ for all i. By induction on the weight, any relation can be represented as a sum of minimal relations (but the representation need not be unique).

Let us give some examples of minimal relations. For each $n \geq 1$, let $\zeta_n = \exp(2\pi i/n)$ be the standard primitive n-th root of unity. For each prime p, let R_p be the relation

$$1 + \zeta_p + \zeta_p^2 + \cdots + \zeta_p^{p-1} = 0.$$

Its minimality follows from the irreducibility of the cyclotomic polynomial. Also we can "rotate" any relation by multiplying through by an arbitrary root of unity to obtain a new relation. In fact, Schoenberg [12] proved that every relation (even those with possibly negative coefficients) can be obtained as a linear combination with positive and negative integral coefficients of the R_p and their rotations. But we are only allowing positive combinations, so it is not clear that these are enough to generate all relations.

In fact it is not even true! In other words, there are other minimal relations. If we subtract R_3 from R_5, cancel the 1's and incorporate the minus signs into the roots of unity, we obtain a new relation

$$\zeta_6 + \zeta_6^{-1} + \zeta_5 + \zeta_5^2 + \zeta_5^3 + \zeta_5^4 = 0, \tag{5}$$

which we will denote $(R_5 : R_3)$. In general, if S and $T_1, T_2, \ldots, T_j$ are relations, we will use the notation $(S : T_1, T_2, \ldots, T_j)$ to denote any relation obtained by rotating the T_i so that each shares exactly one root of unity with S which is different for each i, subtracting them from S, and incorporating the minus signs into the

Weight	Relation type	Number of relations of that type
2	R_2	1
3	R_3	1
5	R_5	1
6	$(R_5 : R_3)$	1
7	$(R_5 : 2R_3)$	2
	R_7	1
8	$(R_5 : 3R_3)$	2
	$(R_7 : R_3)$	1
9	$(R_5 : 4R_3)$	1
	$(R_7 : 2R_3)$	3
10	$(R_7 : 3R_3)$	5
	$(R_7 : R_5)$	1
11	$(R_7 : 4R_3)$	5
	$(R_7 : R_5, R_3)$	6
	$(R_7 : (R_5 : R_3))$	6
	R_{11}	1
12	$(R_7 : 5R_3)$	3
	$(R_7 : R_5, 2R_3)$	15
	$(R_7 : (R_5 : R_3), R_3)$	36
	$(R_7 : (R_5 : 2R_3))$	14
	$(R_{11} : R_3)$	1

TABLE 1. The 107 minimal relations of weight up to 12.

roots of unity. For notational convenience, we will write $(R_5 : 4R_3)$ for $(R_5 : R_3, R_3, R_3, R_3)$, for example. Note that although $(R_5 : R_3)$ denotes unambiguously (up to rotation) the relation listed in (5), in general there will be many relations of type $(S : T_1, T_2, \ldots, T_j)$ up to rotational equivalence. Let us also remark that including R_2's in the list of T's has no effect.

It turns out that recursive use of the construction above is enough to generate all minimal relations of weight up to 12. These are listed in Table 1. The completeness and correctness of the table will be proved in Theorem 3 below. Although there are 107 minimal relations up to rotational equivalence, often the minimal relations within one of our classes are Galois conjugates. For example, the two minimal relations of type $(R_5 : 2R_3)$ are conjugate under $\mathrm{Gal}(\mathbb{Q}(\zeta_{15})/\mathbb{Q})$, as pointed out in [8].

The minimal relations with $k \leq 7$ (k defined as in (4)) had been previously catalogued in [8], and those with $k \leq 9$ in [2]. In fact, the a_i in these never exceed 1, so these also have weight less than or equal to 9.

Theorem 3. *Table 1 is a complete listing of the minimal relations of weight up to 12 (up to rotation).*

The following three lemmas will be needed in the proof.

Lemma 1. *If the relation (4) is minimal, then there are distinct primes $p_1 < p_2 < \cdots < p_s \leq k$ so that each η_i is a $p_1 p_2 \cdots p_s$-th root of unity, after the relation has been suitably rotated.*

Proof. This is a corollary of Theorem 1 in [8]. □

Lemma 2. *The only minimal relations (up to rotation) involving only the $2p$-th roots of unity, for p prime, are R_2 and R_p.*

Proof. Any $2p$-th root of unity is of the form $\pm\zeta^i$. If both $+\zeta^i$ and $-\zeta^i$ occurred in the same relation, then R_2 occurs as a subrelation. So the relation has the form

$$\sum_{i=0}^{p-1} c_i \zeta_p^i = 0$$

By the irreducibility of the cyclotomic polynomial, $\{1, \zeta_p, \ldots, \zeta_p^{p-1}\}$ are independent over $\mathbb{Q}$ save for the relation that their sum is zero, so all the c_i must be equal. If they are all positive, then R_p occurs as a subrelation. If they are all negative, then R_p rotated by -1 (i.e., 180 degrees) occurs as a subrelation. □

Lemma 3. *Suppose S is a minimal relation, and $p_1 < p_2 < \cdots < p_s$ are picked as in Lemma 1 with $p_1 = 2$ and p_s minimal. If $w(S) < 2p_s$, then S (or a rotation) is of the form $(R_{p_s} : T_1, T_2, \ldots, T_j)$ where the T_i are minimal relations not equal to R_2 and involving only $p_1 p_2 \cdots p_{s-1}$-th roots of unity, such that $j < p_s$ and*

$$\sum_{i=1}^{j} [w(T_i) - 2] = w(S) - p_s.$$

Proof. Since every $p_1 p_2 \ldots p_s$-th root of unity is uniquely expressible as the product of a $p_1 p_2 \ldots p_{s-1}$-th root of unity and a p_s-th root of unity, the relation can be rewritten as

$$\sum_{i=0}^{p_s-1} f_i \zeta_{p_s}^i = 0, \tag{6}$$

where each f_i is a sum of $p_1 p_2 \ldots p_{s-1}$-th roots of unity, which we will think of as a sum (not just its value).

Let K_m be the field obtained by adjoining the $p_1 p_2 \ldots p_m$-th roots of unity to $\mathbb{Q}$. Since $[K_s : K_{s-1}] = \phi(p_1 p_2 \cdots p_s)/\phi(p_1 p_2 \cdots p_{s-1}) = \phi(p_s) = p_s - 1$, the only linear relation satisfied by $1, \zeta_{p_s}, \ldots, \zeta_{p_s}^{p_s-1}$ over K_{s-1} is that their sum is zero. Hence (6) forces the values of the f_i to be equal.

The total number of roots of unity in all the f_i's is $w(S) < 2p_s$, so by the pigeonhole principle, some f_i is zero or consists of a single root of unity. In the former case, each f_j sums to zero, but at least two of these sums contain at least one root of unity, since otherwise s was not minimal, so one of these sums gives a subrelation of S, contradicting its minimality. So some f_i consists of a single root of unity. By rotation, we may assume $f_0 = 1$. Then each f_i sums to 1, and if it is not simply the single root of unity 1, the negatives of the roots of unity in f_i together with 1 form a relation T_i which is not R_2 and involves only $p_1 p_2 \cdots p_{s-1}$-th roots of unity, and it is clear that S is of type $(R_{p_s} : T_{i_1}, T_{i_2}, \ldots, T_{i_j})$. If one of the T's were not minimal, then it could be decomposed into two nontrivial subrelations, one of which would not share a root of unity with the R_{p_s}, and this would give a nontrivial subrelation of S, contradicting the minimality of S. Finally, $w(S)$ must equal the sum of the weights of R_{p_s} and the T's, minus $2j$ to account for the roots of unity that are cancelled in the construction of $(R_{p_s} : T_{i_1}, T_{i_2}, \ldots, T_{i_j})$. □

Proof of Theorem 3. We will content ourselves with proving that every relation of weight up to 12 can be decomposed into a sum of the ones listed in Table 1, it then being straightforward to check that the entries in the table are distinct, and that none of them can be further decomposed into relations higher up in the table.

Let S be a minimal relation with $w(S) \leq 12$. Pick $p_1 < p_2 < \cdots < p_s$ as in Lemma 1 with $p_1 = 2$ and p_s minimal. In particular, $p_s \leq 12$, so $p_s = 2,3,5,7$, or 11.

Case 1: $p_s \leq 3$

Here the only minimal relations are R_2 and R_3, by Lemma 2.

Case 2: $p_s = 5$

If $w(S) < 10$, then we may apply Lemma 3 to deduce that S is of type $(R_5 : T_1, T_2, \ldots, T_j)$ Each T must be R_3 (since $p_{s-1} \leq 3$), and $j = w(S) - 5$ by the last equation in Lemma 3. The number of relations of type $(R_5 : jR_3)$, up to rotation, is $\binom{5}{j}/5$. (There are $\binom{5}{j}$ ways to place the R_3's, but one must divide by 5 to avoid counting rotations of the same relation.)

If $10 \leq w(S) \leq 12$, then write S as in (6). If some f_i consists of zero or one roots of unity, then the argument of Lemma 3 applies, and S must be of the form $(R_5 : jR_3)$ with $j \leq 4$, which contradicts the last equation in the Lemma. Otherwise the numbers of (sixth) roots of unity occurring in f_0, f_1, f_2, f_3, f_4 must be 2,2,2,2,2 or 2,2,2,2,3 or 2,2,2,3,3 or 2,2,2,2,4 in some order. So the common value of the f_i is a sum of two sixth roots of unity. By rotating by a sixth root of unity, we may assume this value is 0, 1, $1 + \zeta_6$, or 2. If it is 0 or 1, then the arguments in the proof of Lemma 3 apply. Next assume it is $1 + \zeta_6$. The only way two sixth roots of unity can sum to $1 + \zeta_6$ is if they are 1 and ζ_6 in some order. The only ways three sixth roots of unity can sum to $1 + \zeta_6$ is if they are $1, 1, \zeta_6^2$ or $\zeta_6, \zeta_6, \zeta_6^{-1}$. So if the numbers of roots of unity occurring in f_0, f_1, f_2, f_3, f_4 are 2,2,2,2,2 or 2,2,2,2,3, then S will contain R_5 or its rotation by ζ_6, and the same will be true for 2,2,2,3,3 unless the two f_i with three terms are $1 + 1 + \zeta_6^2$ and $\zeta_6 + \zeta_6 + \zeta_6^{-1}$, in which case S contains $(R_5 : R_3)$. It is impossible to write $1 + \zeta_6$ as a sum of sixth roots of unity without using 1 or ζ_6, so if the numbers are 2,2,2,2,4, then again S contains R_5 or its rotation by ζ_6. Thus we get no new relations where the common value of the f_i is $1 + \zeta_6$. Lastly, assume this common value is 2. Any representation of 2 as a sum of four or fewer sixth roots of unity contains 1, unless it is $\zeta_6 + \zeta_6 + \zeta_6^{-1} + \zeta_6^{-1}$, so S will contain R_5 except possibly in the case where f_0, f_1, f_2, f_3, f_4 are 2,2,2,2,4 in some order, and the 4 is as above. But in this final remaining case, S contains $(R_5 : R_3)$. Thus there are no minimal relations S with $p_s = 5$ and $10 \leq w(S) \leq 12$.

Case 3: $p_s = 7$

Since $w(S) \leq 12 < 2 \cdot 7$, we can apply Lemma 3. Now the sum of $w(T_i) - 2$ is required to be $w(S) - 7$ which is at most 5, so the T's that may be used are R_3, R_5, $(R_5 : R_3)$, and the two of type $(R_5 : 2R_3)$, for which weight minus 2 equals 1, 3, 4, and 5, respectively. So the problem is reduced to listing the partitions of $w(S) - 7$ into parts of size 1, 3, 4, and 5.

If all parts used are 1, then we get $(R_7 : jR_3)$ with $j = w(S) - 7$, and there are $\binom{7}{j}/7$ distinct relations in this class. Otherwise exactly one part of size 3, 4, or 5 is used, and the possibilities are as follows. If a part of size 3 is used, we get $(R_7 : R_5)$, $(R_7 : R_5, R_3)$, or $(R_7 : R_5, 2R_3)$, of weights 10, 11, 12 respectively. By rotation, the R_5 may be assumed to share the 1 in the R_7, and then there are $\binom{6}{i}$

Partition	Relation type
12	$(R_7 : 5R_3)$
	$(R_7 : R_5, 2R_3)$
	$(R_7 : (R_5 : R_3), R_3)$
	$(R_7 : (R_5 : 2R_3))$
	$(R_{11} : R_3)$
10,2	$(R_7 : 3R_3) + R_2$
	$(R_7 : R_5) + R_2$
9,3	$(R_5 : 4R_3) + R_3$
	$(R_7 : 2R_3) + R_3$
8,2,2	$(R_5 : 3R_3) + 2R_2$
	$(R_7 : R_3) + 2R_2$
7,5	$(R_5 : 2R_3) + R_5$
	$R_7 + R_5$
7,3,2	$(R_5 : 2R_3) + R_3 + R_2$
	$R_7 + R_3 + R_2$
6,6	$2(R_5 : R_3)$
6,3,3	$(R_5 : R_3) + 2R_3$
6,2,2,2	$(R_5 : R_3) + 3R_2$
5,5,2	$2R_5 + R_2$
5,3,2,2	$R_5 + R_3 + 2R_2$
3,3,3,3	$4R_3$
3,3,2,2,2	$2R_3 + 3R_2$
2,2,2,2,2,2	$6R_2$

TABLE 2. The types of relations of weight 12.

ways to place the R_3's where i is the number of R_3's. If a part of size 4 is used, we get $(R_7 : (R_5 : R_3))$ of weight 11 or $(R_7 : (R_5 : R_3), R_3)$ of weight 12. By rotation, the $(R_5 : R_3)$ may be assumed to share the 1 in the R_7, but any of the six roots of unity in the $(R_5 : R_3)$ may be rotated to be 1. The R_3 can then overlap any of the other 6 seventh roots of unity. Finally, if a part of size 5 is used, we get $(R_7 : (R_5 : 2R_3))$. There are two different relations of type $(R_5 : 2R_3)$ that may be used, and each has seven roots of unity which may be rotated to be the 1 shared by the R_7, so there are 14 of these all together.

Case 4: $p_s = 11$

Applying Lemma 3 shows that the only possibilities are R_{11} of weight 11, and $(R_{11} : R_3)$ of weight 12. □

Now a general relation of weight 12 is a sum of the minimal ones of weight up to 12, and we can classify them according to the weights of the minimal relations, which form a partition of 12 with no parts of size 1 or 4. We will use the notation $(R_5 : 2R_3) + 2R_3$, for example, to denote a sum of three minimal relations of type $(R_5 : 2R_3)$, R_3, and R_3. Table 2 lists the possibilities. The parts may be rotated independently, so any category involving more than one minimal relation contains infinitely many relations, even up to rotation (of the entire relation). Also, the categories are not mutually exclusive, because of the non-uniqueness of the decomposition into minimal relations.

4. Solutions to the trigonometric equation

Here we use the classification of the previous section to give a complete listing of the solutions to the trigonometric equation (2). There are some obvious solutions to (2), namely those in which U, V, W are arbitary positive rational numbers with sum $1/2$, and X, Y, Z are a permutation of U, V, W. We will call these the trivial solutions, even though the three-diagonal intersections they give rise to can look surprising. See Figure 3 for an example on the 16-gon.

The twelve roots of unity occurring in (3) are not arbitrary; therefore we must go through Table 2 to see which relations are of the correct form, i.e., expressible

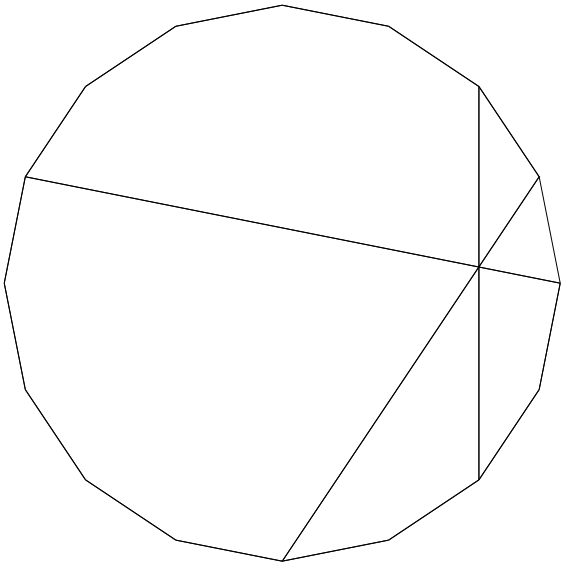

FIGURE 3. A surprising trivial solution for the 16-gon. The intersection point does not lie on any of the 16 lines of symmetry of the 16-gon.

as a sum of six roots of unity and their inverses, where the product of the six is -1. First let us prove a few lemmas that will greatly reduce the number of cases.

Lemma 4. *Let S be a relation of weight $k \leq 12$. Suppose S is stable under complex conjugation (i.e., under $\zeta \mapsto \zeta^{-1}$). Then S has a complex conjugation-stable decomposition into minimal relations; i.e., each minimal relation occurring is itself stable under complex conjugation, or can be paired with another minimal relation which is its complex conjugate.*

Proof. We will use induction on k. If S is minimal, there is nothing to prove. Otherwise let T be a (minimal) subrelation of S of minimal weight, so T is of weight at most 6. The complex conjugate $\overline{T}$ of T is another minimal relation in S. If they do not intersect, then we take the decomposition of S into T, $\overline{T}$, and a decomposition of $S \setminus (T \cup \overline{T})$ given by the inductive hypothesis. If they do overlap and the weight of T is at most 5, then $T = R_p$ for some prime p, and the fact that T intersects $\overline{T}$ implies that $T = \overline{T}$, and we get the result by applying the inductive hypothesis to $S \setminus T$.

The only remaining case is where S is of type $2(R_5 : R_3)$. If the two $(R_5 : R_3)$'s are not conjugate to each other, then for each there is a root of unity ζ such that ζ and ζ^{-1} occur in that (rotation of) $(R_5 : R_3)$. The quotient ζ^2 is then a 30-th root of unity, so ζ itself is a 60-th root of unity. Thus each $(R_5 : R_3)$ is a rotation of the "standard" $(R_5 : R_3)$ as in (5) by a 60-th root of unity, and we let Mathematica check the 60^2 possibilities. □

We do not know if the preceding lemma holds for relations of weight greater than 12.

U	V	W	X	Y	Z	Range
$1/6$	t	$1/3-2t$	$1/3+t$	t	$1/6-t$	$0<t<1/6$
$1/6$	$1/2-3t$	t	$1/6-t$	$2t$	$1/6+t$	$0<t<1/6$
$1/6$	$1/6-2t$	$2t$	$1/6-2t$	t	$1/2+t$	$0<t<1/12$
$1/3-4t$	t	$1/3+t$	$1/6-2t$	$3t$	$1/6+t$	$0<t<1/12$

TABLE 3. The nontrivial infinite families of solutions to (2).

Lemma 5. *Let S be a minimal relation of type $(R_p : T_1, \dots, T_j)$, $p \geq 5$, where the T_i involve roots of unity of order prime to p, and $j < p$. If S is stable under complex conjugation, then the particular rotation of R_p from which the T_i were "subtracted" is also stable (and hence so is the collection of the relations subtracted).*

Proof. Let ℓ be the product of the orders of the roots of unity in all the T_i. The elements of S in the original R_p can be characterized as those terms of S that are unique in their coset of μ_ℓ (the ℓ-th roots of unity), and this condition is stable under complex conjugation, so the set of terms of the R_p that were not subtracted is stable. Since $j < p$, we can pick one such term ζ. Then the quotient ζ/ζ^{-1} is a p-th root of unity, so ζ is a $2p$-th root of unity, and hence the R_p containing it is stable. □

Corollary 1. *A relation of type $(R_7 : (R_5 : R_3), R_3)$ cannot be stable under complex conjugation.*

Even with these restrictions, a very large number of cases remain, so we perform the calculation using Mathematica. Each entry of Table 2 represents a finite number of linearly parameterized (in the exponents) families of relations of weight 12. For each parameterized family, we check to see what additional constraints must be put on the parameters for the relation to be of the form of (3). Next, for each parameterized family of solutions to (3), we calculate the corresponding U, V, W, X, Y, Z and throw away solutions in which some of these are nonpositive. Finally, we sort U, V, W and X, Y, Z and interchange the two triples if $U > X$, in order to count the solutions only up to symmetry.

The results of this computation are recorded in the following theorem.

Theorem 4. *The positive rational solutions to (2), up to symmetry, can be classified as follows:*

1. *The trivial solutions, which arise from relations of type $6R_2$.*
2. *Four one-parameter families of solutions, listed in Table 3. The first arises from relations of type $4R_3$, and the other three arise from relations of type $2R_3 + 3R_2$.*
3. *Sixty-five "sporadic" solutions, listed in Table 4, which arise from the other types of weight 12 relations listed in Table 2.*

The only duplications in this list are that the second family of Table 3 gives a trivial solution for $t = 1/12$, the first and fourth families of Table 3 give the same solution when $t = 1/18$ in both, and the second and fourth families of Table 3 give the same solution when $t = 1/24$ in both.

Some explanation of the tables is in order. The last column of Table 3 gives the allowable range for the rational parameter t. The entries of Table 4 are sorted

TABLE 4. The 65 sporadic solutions to (2).

according to the least common denominator of U, V, W, X, Y, Z, which is also the least n for which diagonals of a regular n-gon can create arcs of the corresponding lengths. The relation type from which each solution derives is also given. The reason 11 does not appear in the least common denominator for any sporadic solution is that the relation $(R_{11} : R_3)$ cannot be put in the form of (3) with the α_j summing to 1, and hence leads to no solutions of (2). (Several other types of relations also give rise to no solutions.)

Tables 3 and 4 are the same as Bol's tables at the bottom of page 40 and on page 41 of [1], in a slightly different format.

The arcs cut by diagonals of a regular n-gon have lengths which are multiples of $2\pi/n$, so U, V, W, X, Y and Z corresponding to any configuration of three diagonals meeting must be multiples of $1/n$. With this additional restriction, trivial solutions to (2) occur only when n is even (and at least 6). Solutions within the infinite families of Table 3 occur when n is a multiple of 6 (and at least 12), and there t must be a multiple of $1/n$. Sporadic solutions with least common denominator d occur if and only if n is a multiple of d.

5. Intersections of more than three diagonals

Now that we know the configurations of three diagonals meeting, we can check how they overlap to produce configurations of more than three diagonals meeting. We will disregard configurations in which the intersection point is the center of the n-gon, since these are easily described: there are exactly $n/2$ diagonals (diameters) through the center when n is even, and none otherwise.

When k diagonals meet, they form $2k$ arcs, whose lengths we will measure as a fraction of the whole circumference (so they will be multiples of $1/n$) and list in counterclockwise order. (Warning: this is different from the order used in Tables 3 and 4.) The least common denominator of the numbers in this list will be called the denominator of the configuration. It is the least n for which the configuration can be realized as diagonals of a regular n-gon.

Lemma 6. *If a configuration of $k \geq 2$ diagonals meeting at an interior point other than the center has denominator dividing d, then any configuration of diagonals meeting at that point has denominator dividing* $\mathrm{LCM}(2d, 3)$.

Proof. We may assume $k = 2$. Any other configuration of diagonals through the intersection point is contained in the union of configurations obtained by adding one diagonal to the original two, so we may assume the final configuration consists of three diagonals, two of which were the original two. Now we need only go through our list of three-diagonal intersections.

It can be checked (using Mathematica) that removing any diagonal from a sporadic configuration of three intersecting diagonals yields a configuration whose denominator is the same or half as much, except that it is possible that removing a diagonal from a three-diagonal configuration of denominator 210 or 60 yields one of denominator 70 or 20, respectively, which proves the desired result for these cases. The additive group generated by 1/6 and the normalized arc lengths of a configuration obtained by removing a diagonal from a configuration corresponding to one of the families of Table 3 contains $2t$ where t is the parameter, (as can be verified using Mathematica again), which means that adding that third diagonal can at most double the denominator (and throw in a factor of 3, if it isn't already

TABLE 5. The one-parameter families of four-diagonal configurations.

there). Similarly, it is easily checked (even by hand), that the subgroup generated by the normalized arc lengths of a configuration obtained by removing one of the three diagonals of a configuration corresponding to a trivial solution to (2) but with intersection point not the center, contains twice the arc lengths of the original configuration. □

Corollary 2. *If a configuration of three or more diagonals meeting includes three forming a sporadic configuration, then its denominator is 30, 42, 60, 84, 90, 120, 168, 180, 210, 240, or 420.*

Proof. Combine the lemma with the list of denominators of sporadic configurations listed in Table 4. □

For $k \geq 4$, a list of $2k$ positive rational numbers summing to 1 arises this way if and only if the lists of length $2k-2$ which would arise by removing the first or second diagonal actually correspond to $k-1$ intersecting diagonals. Suppose $k=4$. If we specify the sporadic configuration or parameterized family of configurations that arise when we remove the first or second diagonal, we get a set of linear conditions on the eight arc lengths. Corollary 2 tells us that we get a configuration with denominator among 30, 42, 60, 84, 90, 120, 168, 180, 210, 240, and 420, if one of these two is sporadic. Using Mathematica to perform this computation for the rest of possibilities in Theorem 4 shows that the other four-diagonal configurations, up to rotation and reflection, fall into 12 one-parameter families, which are listed in Table 5 by the eight normalized arc lengths and the range for the parameter t, with a finite number of exceptions of denominators among 12, 18, 24, 30, 36, 42, 48, 60, 84, and 120.

We will use a similar argument when $k=5$. Any five-diagonal configuration containing a sporadic three-diagonal configuration will again have denominator among 30, 42, 60, 84, 90, 120, 168, 180, 210, 240, and 420. Any other five-diagonal configuration containing one of the exceptional four-diagonal configurations will have denominator among 12, 18, 24, 30, 36, 42, 48, 60, 72, 84, 96, 120, 168, and 240, by Lemma 6. Finally, another Mathematica computation shows that the one-parameter families of four-diagonal configurations overlap to produce the

										Range

t	$1/6-2t$	$2t$	$1/3-4t$	$3t$	$3t$	$1/3-4t$	$2t$	$1/6-2t$	t	$0<t<1/12$

TABLE 6. The one-parameter families of five-diagonal configurations.

one-parameter families listed (up to rotation and reflection) in Table 6, and a finite number of exceptions of denominators among 18, 24, and 30.

For $k=6$, any six-diagonal configuration containing a sporadic three-diagonal configuration will again have denominator among 30, 42, 60, 84, 90, 120, 168, 180, 210, 240, and 420. Any six-diagonal configuration containing one of the exceptional four-diagonal configurations will have denominator among 12, 18, 24, 30, 36, 42, 48, 60, 72, 84, 96, 120, 168, and 240. Any six-diagonal configuration containing one of the exceptional five-diagonal configurations will have denominator among 18, 24, 30, 36, 48, and 60. Another Mathematica computation shows that the one-parameter families of five-diagonal configurations cannot combine to give a six-diagonal configuration.

Finally for $k \geq 7$, any k-diagonal configuration must contain an exceptional configuration of 3, 4, or 5 diagonals, and hence by Lemma 6 has denominator among 12, 18, 24, 30, 36, 42, 48, 60, 72, 84, 90, 96, 120, 168, 180, 210, 240, and 420.

We summarize the results of this section in the following.

Proposition 1. *The configurations of $k \geq 4$ diagonals meeting at a point not the center, up to rotation and reflection, fall into the one-parameter families listed in Tables 5 and 6, with finitely many exceptions (for fixed k) of denominators among 12, 18, 24, 30, 36, 42, 48, 60, 72, 84, 90, 96, 120, 168, 180, 210, 240, and 420.*

In fact, many of the numbers listed in the proposition do not actually occur as denominators of exceptional configurations. For example, it will turn out that the only denominator greater than 120 that occurs is 210.

6. The formula for intersection points

Let $a_k(n)$ denote the number of points inside the regular n-gon other than the center where exactly k lines meet. Let $b_k(n)$ denote the number of k-tuples of diagonals which meet at a point inside the n-gon other than the center. Each interior point at which exactly m diagonals meet gives rise to $\binom{m}{k}$ such k-tuples, so we have the relationship

$$b_k(n) = \sum_{m \geq k} \binom{m}{k} a_m(n) \tag{7}$$

Since every four distinct vertices of the n-gon determine one pair of diagonals which intersect inside, the number of such pairs is exactly $\binom{n}{4}$, but if n is even, then $\binom{n/2}{2}$ of these are pairs which meet at the center, so

$$b_2(n) = \binom{n}{4} - \binom{n/2}{2}\delta_2(n). \tag{8}$$

(Recall that $\delta_m(n)$ is defined to be 1 if n is a multiple of m, and 0 otherwise.)

We will use the results of the previous two sections to deduce the form of $b_k(n)$ and then the form of $a_k(n)$. To avoid having to repeat the following, let us make a definition.

Definition . A function on integers $n \geq 3$ will be called *tame* if it is a linear combination (with rational coefficients) of the functions n^3, n^2, n, 1, $n^2\delta_2(n)$, $n\delta_2(n)$, $\delta_2(n)$, $\delta_4(n)$, $n\delta_6(n)$, $\delta_6(n)$, $\delta_{12}(n)$, $\delta_{18}(n)$, $\delta_{24}(n)$, $\delta_{24}(n-6)$, $\delta_{30}(n)$, $\delta_{36}(n)$, $\delta_{42}(n)$, $\delta_{48}(n)$, $\delta_{60}(n)$, $\delta_{72}(n)$, $\delta_{84}(n)$, $\delta_{90}(n)$, $\delta_{96}(n)$, $\delta_{120}(n)$, $\delta_{168}(n)$, $\delta_{180}(n)$, $\delta_{210}(n)$, and $\delta_{420}(n)$.

Proposition 2. *For each $k \geq 2$, the function $b_k(n)/n$ on integers $n \geq 3$ is tame.*

Proof. The case $k = 2$ is handled by (8), so assume $k \geq 3$. Each list of $2k$ normalized arc lengths as in Section 5 corresponding to a configuration of k diagonals meeting at a point other than the center, considered up to rotation (but not reflection), contributes n to $b_k(n)$. (There are n places to start measuring the arcs from, and these n configurations are distinct, because the corresponding intersection points differ by rotations of multiples of $2\pi/n$, and by assumption they are not at the center.) So $b_k(n)/n$ counts such lists.

Suppose $k = 3$. When n is even, the family of trivial solutions to the trigonometric equation (2) has $U = a/n$, $V = b/n$, $W = c/n$, where a, b, and c are positive integers with sum $n/2$, and X, Y, and Z are some permutation of U, V, W. Each permutation gives rise to a two-parameter family of six-long lists of arc lengths, and the number of lists within each family is the number of partitions of $n/2$ into three positive parts, which is a quadratic polynomial in n. Similarly each family of solutions in Table 3 gives rise to a number of one-parameter families of lists, when n is a multiple of 6, each containing $\lceil n/6 \rceil - 1$ or $\lceil n/12 \rceil - 1$ lists. These functions of n (extended to be 0 when 6 does not divide n) are expressible as a linear combination of $n\delta_6(n)$, $\delta_6(n)$, and $\delta_{12}(n)$. Finally the sporadic solutions to 2 give rise to a finite number of lists, having denominators among 30, 42, 60, 84, 90, 120, and 210, so their contribution to $b_3(n)/n$ is a linear combination of $\delta_{30}(n), \ldots, \delta_{210}(n)$.

But these families of lists overlap, so we must use the Principle of Inclusion-Exclusion to count them properly. To show that the result is a tame function, it suffices to show that the number of lists in any intersection of these families is a tame function. When two of the trivial families overlap but do not coincide, they overlap where two of the a, b, and c above are equal, and the corresponding lists lie in one of the one-parameter families $(t, t, t, t, 1/2 - 2t, 1/2 - 2t)$ or $(t, t, t, 1/2 - 2t, t, 1/2 - 2t)$ (with $0 < t < 1/4$), each of which contain $\lceil n/4 \rceil - 1$ lists (for n even). This function of n is a combination of $n\delta_2(n)$, $\delta_2(n)$, and $\delta_4(n)$, hence it is tame. Any other intersection of the infinite families must contain the intersection of two one-parameter families which are among the two above or arise from Table 3, and a Mathematica computation shows that such an intersection consists of at most a single list of denominator among 6, 12, 18, 24, and 30. And, of course, any intersection involving a single sporadic list, can contain at most that sporadic list. Thus the number of lists within any intersection is a tame function of n. Finally we must delete the lists which correspond to configurations of diagonals meeting at the center. These are the lists within the trivial two-parameter family $(t, u, 1/2 - t - u, t, u, 1/2 - t - u)$, so their number is also a tame function of n, by the Principle of Inclusion-Exclusion again. Thus $b_3(n)/n$ is tame.

Next suppose $k = 4$. The number of lists within each family listed in Table 5, or the reflection of such a family, is (when n is divisible by 6) the number of multiples of $1/n$ strictly between α and β, where the range for the parameter t is $\alpha < t < \beta$. This number is $\lceil \beta n \rceil - 1 - \lfloor \alpha n \rfloor$. Since the table shows that α and β are always multiples of $1/24$, this function of n is expressible as a combination of $n\delta_6(n)$ and a function on multiples of 6 depending only on n mod 24, and the latter can be written as a combination of $\delta_6(n)$, $\delta_{12}(n)$, $\delta_{24}(n)$, and $\delta_{24}(n-6)$, so it is tame. Mathematica shows that when two of these families are not the same, they intersect in at most a single list of denominator among 6, 12, 18, and 24. So these and the exceptions of Proposition 1 can be counted by a tame function. Thus, again by the Principle of Inclusion-Exclusion, $b_4(n)/n$ is tame.

The proof for $k = 5$ is identical to that of $k = 4$, using Table 6 instead of Table 5, and using another Mathematica computation which shows that the intersections of two one-parameter families of lists consist of at most a single list of denominator 24.

The proof for $k \geq 6$ is even simpler, because then there are only the exceptional lists. By Proposition 1, $b_k(n)/n$ is a linear combination of $\delta_m(n)$ where m ranges over the possible denominators of exceptional lists listed in the proposition, so it is tame. □

Lemma 7. *A tame function is determined by its values at $n = 3$, 4, 5, 6, 7, 8, 9, 10, 12, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 84, 90, 96, 120, 168, 180, 210, and 420.*

Proof. By linearity, it suffices to show that if a tame function f is zero at those values, then f is the zero linear combination of the functions in the definition of a tame function. The vanishing at $n = 3$, 5, 7, and 9 forces the coefficients of n^3, n^2, n, and 1 to vanish, by Lagrange interpolation. Then comparing the values at $n = 4$ and $n = 10$ shows that the coefficient of $\delta_4(n)$ is zero. The vanishing at $n = 4$, 8, and 10 forces the coefficients of $n^2\delta_2(n)$, $n\delta_2(n)$, and $\delta_2(n)$ to vanish. Comparing the values at $n = 6$ and $n = 54$ shows that the coefficient of $n\delta_6$ is zero. Comparing the values at $n = 6$ and $n = 66$ shows that the coefficient of $\delta_2 4(n-6)$ is zero.

At this point, we know that $f(n)$ is a combination of $\delta_m(n)$, for $m = 6$, 12, 18, 24, 30, 36, 42, 48, 60, 72, 84, 90, 96, 120, 168, 180, 210, and 420. For each m in turn, $f(m) = 0$ now implies that the coefficient of $\delta_m(n)$ is zero. □

Proof of Theorem 1. Computation (see the appendix) shows that the tame function $b_8(n)/n$ vanishes at all the numbers listed in Lemma 7. Hence by that lemma, $b_8(n) = 0$ for all n. Thus by (7), $a_k(n)$ and $b_k(n)$ are identically zero for all $k \geq 8$ as well.

By reverse induction on k, we can invert (7) to express $a_k(n)$ as a linear combination of $b_m(n)$ with $m \geq k$. Hence $a_k(n)/n$ is tame as well for each $k \geq 2$.

Computation shows that the equations

$$\begin{aligned}
a_2(n)/n &= (n^3-6n^2+11n-6)/24+(-5n^2+46n-72)/16\cdot\delta_2(n)\\
&\quad -9/4\cdot\delta_4(n)+(-19n+110)/2\cdot\delta_6(n)+54\cdot\delta_{12}(n)+84\cdot\delta_{18}(n)\\
&\quad +50\cdot\delta_{24}(n)-24\cdot\delta_{30}(n)-100\cdot\delta_{42}(n)-432\cdot\delta_{60}(n)\\
&\quad -204\cdot\delta_{84}(n)-144\cdot\delta_{90}(n)-204\cdot\delta_{120}(n)-144\cdot\delta_{210}(n)\\
a_3(n)/n &= (5n^2-48n+76)/48\cdot\delta_2(n)+3/4\cdot\delta_4(n)+(7n-38)/6\cdot\delta_6(n)\\
&\quad -8\cdot\delta_{12}(n)-20\cdot\delta_{18}(n)-16\cdot\delta_{24}(n)-19\cdot\delta_{30}(n)+8\cdot\delta_{42}(n)\\
&\quad +68\cdot\delta_{60}(n)+60\cdot\delta_{84}(n)+48\cdot\delta_{90}(n)+60\cdot\delta_{120}(n)+48\cdot\delta_{210}(n)\\
a_4(n)/n &= (7n-42)/12\cdot\delta_6(n)-5/2\cdot\delta_{12}(n)-4\cdot\delta_{18}(n)+3\cdot\delta_{24}(n)\\
&\quad +6\cdot\delta_{42}(n)+34\cdot\delta_{60}(n)-6\cdot\delta_{84}(n)-6\cdot\delta_{120}(n)\\
a_5(n)/n &= (n-6)/4\cdot\delta_6(n)-3/2\cdot\delta_{12}(n)-2\cdot\delta_{24}(n)+4\cdot\delta_{42}(n)\\
&\quad +6\cdot\delta_{84}(n)+6\cdot\delta_{120}(n)\\
a_6(n)/n &= 4\cdot\delta_{30}(n)-4\cdot\delta_{60}(n)\\
a_7(n)/n &= \delta_{30}(n)+4\cdot\delta_{60}(n)
\end{aligned}$$

hold for all the n listed in Lemma 7, so the lemma implies that they hold for all $n \geq 3$. These formulas imply the remarks in the introduction about the maximum number of diagonals meeting at an interior point other than the center. Finally

$$\begin{aligned}
I(n) &= \delta_2(n)+\sum_{k=2}^{\infty} a_k(n)\\
&= \delta_2(n)+\sum_{k=2}^{7} a_k(n),
\end{aligned}$$

which gives the desired formula. (The $\delta_2(n)$ in the expression for $I(n)$ is to account for the center point when n is even, which is the only point not counted by the a_k.) □

7. The formula for regions

We now use the knowledge obtained in the proof of Theorem 1 about the number of interior points through which exactly k diagonals pass to calculate the number of regions formed by the diagonals.

Proof of Theorem 2. Consider the graph formed from the configuration of a regular n-gon with its diagonals, in which the vertices are the vertices of the n-gon together with the interior intersection points, and the edges are the sides of the n-gon together with the segments that the diagonals cut themselves into. As usual, let V denote the number of vertices of the graph, E the number of edges, and F the number of regions formed, including the region outside the n-gon. We will employ Euler's Formula $V - E + F = 2$.

Clearly $V = n + I(n)$. We will count edges by counting their ends, which are $2E$ in number. Each vertex has $n-1$ edge ends, the center (if n is even) has n edge ends, and any other interior point through which exactly k diagonals pass has $2k$

edge ends, so

$$2E = n(n-1) + n\delta_2(n) + \sum_{k=2}^{\infty} 2k a_k(n).$$

So the desired number of regions, not counting the region outside the n-gon, is

$$\begin{aligned} F - 1 &= E - V + 1 \\ &= \left[n(n-1)/2 + n\delta_2(n)/2 + \sum_{k=2}^{\infty} k a_k(n) \right] - [n + I(n)] + 1. \end{aligned}$$

Substitution of the formulas derived in the proof of Theorem 1 for $a_k(n)$ and $I(n)$ yields the desired result. □

Appendix: computations and tables

In Table 7 we list $I(n), R(n), a_2(n), \ldots, a_7(n)$ for $n = 4, 5, \ldots, 30$. To determine the polynomials listed in Theorem 1 more data was needed especially for $n \equiv 0 \bmod 6$. The largest n for which this was required was 420. For speed and memory conservation, we took advantage of the regular n-gon's rotational symmetry and focused our attention on only $2\pi/n$ radians of the n-gon. The data from this computation is found in Table 8. Although we only needed to know the values at those n listed in Lemma 7 of Section 6, we give a list for $n = 6, 12, \ldots, 420$ so that the nice patterns can be seen.

The numbers in these tables were found by numerically computing (using a C program and 64 bit precision) all possible $\binom{n}{4}$ intersections, and sorting them by their x coordinate. We then focused on runs of points with close x coordinates, looking for points with close y coordinates.

Several checks were made to eliminate any fears (arising from round-off errors) of distinct points being mistaken as close. First, the C program sent data to Maple which checked that the coordinates of close points agreed to at least 40 decimal places. Second, we verified for each n that close points came in counts of the form $\binom{k}{2}$ (k diagonals meeting at a point give rise to $\binom{k}{2}$ close points. Hence, any run whose length is not of this form indicates a computational error).

A second program was then written and run on a second machine to make the computations completely rigorous. It also found the intersection points numerically, sorted them and looked for close points, but, to be absolutely sure that a pair of close points p_1 and p_2 were actually the same, it checked that for the two pairs of diagonals (l_1, l_2) and (l_3, l_4) determining p_1 and p_2, respectively, the triples l_1, l_2, l_3 and l_1, l_2, l_4 each divided the circle into arcs of lengths consistent with Theorem 4. Since this test only involves comparing rational numbers, it could be performed exactly.

A word should also be said concerning limiting the search to $2\pi/n$ radians of the n-gon. Both programs looked at slightly smaller slices of the n-gon to avoid problems caused by points near the boundary. We further subdivided this region into twenty smaller pieces to make the task of sorting the intersection points manageable. More precisely, we limited our search to points whose angle with the origin fell between $[c_1 + 2\pi(m-1)/(20n) + \varepsilon, c_1 + 2\pi m/(20n) - \varepsilon)$, $m = 1, 2, \ldots 20$, and also made sure not to include the origin in the count. Here ε was chosen to be .00000000001 and c_1 was chosen to be .00000123 ($c_1 = 0$ would have led to problems since there are many intersection points with angle 0 or $2\pi/n$). To make sure

Lattice-based Information Retrieval

Uta Priss

School of Library and Information Science, Indiana University Bloomington,
upriss@indiana.edu

Abstract. A lattice-based model for information retrieval has been suggested in the 1960's but has been seen as a theoretical possibility hard to practically apply ever since. This paper attempts to revive the lattice model and demonstrate its applicability in an information retrieval system, FaIR, that incorporates a graphical representation of a faceted thesaurus. It shows how Boolean queries can be lattice-theoretically related to the concepts of the thesaurus and visualized within the thesaurus display. An advantage of FaIR is that it allows for a high level of transparency of the system which can be controlled by the user.

1 Introduction

The prevailing model currently used in information retrieval systems is the vector space model. Although it has proven very useful in many applications, it is limited because of the computational complexity of manipulations in high dimensional vector spaces and the problem that only projections in two-, or possibly three-dimensional spaces can be visually represented. In the 1960's other retrieval models were considered besides the vector space model, such as lattice representations, topological spaces, metric spaces and graph models (Salton, 1968) but they were seen as theoretical possibilities that were difficult to practically implement. This paper revisits one of these models, the lattice model, which has been used in many applications within the framework of a theory called formal concept analysis (Ganter & Wille, 1999) but has not yet been widely applied to information retrieval. The retrieval system, FaIR, described in this paper demonstrates that with modern computational technology, especially graphical representations, and some advancement of the methodology the lattice model is feasible. The main result of this paper is the translation of Boolean queries into lattice representations. This paper does not make any claims as to whether the lattice model is superior to any other models but simply shows that the lattice model is feasible. The main purpose of exploring lattice-based approaches is to increase transparency and user control over an information retrieval system that is not a "black box" to the user.

1.1 Lattices in information retrieval

A first detailed formalization of how to use lattices for information retrieval appears to date back to Mooers (1958). His approach is contained in Salton's (1968) famous book and originally received some attention (Soergel, 1967) but has not been further elaborated in the mainstream information retrieval community. Most of the few, current applications of lattices in information retrieval are based on formal concept analysis

(Ganter & Wille, 1999), which was invented in the early 1980's and relates lattices to object-attribute matrices or document-term matrices in information retrieval. Formal concept analysis applications to information retrieval are similar to Mooers's ideas but have been developed independently.

Lattices are used by Fairthorne (1956), Mooers (1958), Soergel (1967), and Salton (1968) to derive a mathematical formalization of a query (or request) language. If a language consists of a set of primitive terms with Boolean AND as the sole operator, then the resulting set of terms can be represented as a Boolean lattice. For example, "A AND B AND C" is superordinate to "A AND B", "A AND C", "B AND C" in a Boolean lattice. If Boolean OR is added, the possible combinations of terms with AND and OR form what is called a free distributive lattice. The number of elements in such a lattice with n terms, AND and OR grows faster than exponentially: a lattice of 3 terms has 20 elements, a lattice of 6 terms has almost 8 million elements, a lattice of 8 terms has 5.6 $\times 10^{22}$ elements (Sloane, 1999). Adding Boolean NOT complicates this even more.

It can be concluded that, although theoretical results concerning query languages and lattices may be interesting, it is not practical to produce a graphical representation of all possible query terms in a lattice. But it should not be concluded that other lattice representations cannot be useful. As an example, a recently developed system, SWEAR (Davis & McKim, 1999), uses lattices implicitly to improve the ranking of result sets. Text-based representations of ranked result sets of Boolean queries are often ordered based on the number of requested terms that appear in the documents. That implies that all nodes of the Boolean lattice that are at the same level are lumped into one rank. SWEAR changes that by superimposing a linear order on the Boolean lattice that assigns a distinct rank to every node based on user-selected term weights.

1.2 Lattices as conceptual hierarchies or thesauri

Although lattices may not be useful for representing all possibilities of Boolean query terms, they are appealing as a means of representing conceptual hierarchies used in information retrieval systems because of some formal lattice properties. The Galois connection of a lattice applied to information retrieval represents an inverse relationship between document sets and query terms: if more query terms are selected, which means the request is more precise, fewer documents are retrieved, and vice versa. This relationship holds in general for conceptual hierarchies: more general concepts have fewer defining attributes in their intension but more objects in their extension, and vice versa. Therefore lattices have been used successfully for representing conceptual hierarchies in formal concept analysis and for type hierarchies in object-oriented modeling. Besides the Galois connection, lattices are superior to tree hierarchies and poly-hierarchies (or ordered sets), which can both be embedded into lattices, because lattices have the property that for every set of elements there exists a unique lowest upper bound (join) and a unique greatest lower bound (meet). This property is useful in many applications.

Formal concept analysis (Ganter & Wille, 1999) represents conceptual hierarchies as mathematical lattices. Each concept has a set of objects as its unique extension and

a set of attributes or characteristics as its unique intension. In information retrieval applications, the documents serve as formal objects and the index terms (descriptors, thesaurus terms) serve as formal attributes (compare, for example, Kollewe et al. (1995)). A document-term matrix can equivalently be transformed into a concept lattice. Figure 1 shows an example. In the lattice diagram, each document is described by exactly those terms that are attached to nodes that are above the document node. Each term belongs to exactly those documents that are attached to nodes below the term node. One problem with this approach is that concept lattices can become fairly large and difficult to generate automatically from the data. Carpineto & Romano (1995) suggest therefore approaches to derive parts of lattices and to use fish-eye view techniques. Godin et al. (1993) represent only the direct neighbors of nodes in a textual interface. The software TOSCANA (Kollewe et al., 1995) facilitates the decomposition of a lattice into smaller lattices that are nested. Users can browse through the lattices by zooming between more abstract and more detailed views.

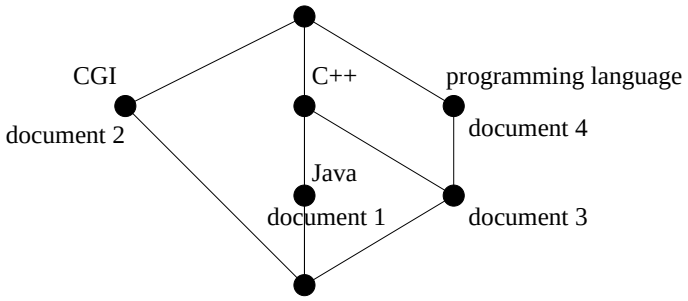

Fig. 1. A document-term matrix and its concept lattice

Most of the applications of lattice theory to information retrieval are data-driven, that is the lattices are constructed from the actual occurrence of documents and terms and not from conceptual relationships among terms that are inherent to the domain knowledge. Therefore, in principle, these approaches face a similar problem to that of the lattice formalisms of the 1960's: all possible combinations can occur and the lattices can become large and complex, although Godin et al. (1993) estimate that the potential maximum complexity is not reached in real applications. Opposed to data-driven approaches are facet-based approaches, which analyze and restrict the possible keyword combinations for each facet; thesaurus-based approaches, which utilize lattices

to model the conceptual hierarchy among the concepts; and faceted thesaurus-based approaches, such as the one presented in this paper, which do both.

As an example of a facet-based approach, a pilot study (Rock & Wille, 2000) compiled index terms of a small library with 2000 books into scales, which loosely correspond to facets. The scales are represented as lattices that contain five to ten index terms and all their combinations that can occur among the documents. The scales were manually generated over a period of several months. Using TOSCANA users can browse and navigate through the scales.

Several applications of formal concept analysis to information retrieval utilize thesauri but not faceted thesauri. Priss (1997) discusses several formal methods of combining a document-term matrix with a thesaurus hierarchy. Other approaches (Skorsky (1997) and Groh et al. (1998)) select a subset of a thesaurus hierarchy and generate all possible term combinations of that subset. This produces conceptual structures that can accommodate any document of that domain. But since not all possible combinations actually occur, the approach creates some redundancy. Furthermore, the thesaurus subsets are not usually facets (i.e. conceptually complete and independent). Groh et al. (1998) present a sophisticated method of combining several subsets of a thesaurus hierarchy into one scale. Since the thesaurus is not faceted, two selected subsets of the thesaurus can conceptually overlap. A combination of subsets has therefore to include new terms that correspond to otherwise missing joins of terms from different subsets. The resulting mathematical structure and graphical representation is fairly complicated. If a faceted thesaurus was used instead, the problem would not arise in the first place because facets are by definition complete and independent (compare Priss & Jacob (1998)).

A further lattice-based approach should be mentioned: Pedersen (1993) describes a ”relationship lattice diagram” that consists of a lattice-based thesaurus hierarchy with additional relations. The approach is similar to formal concept analysis but seems to have been developed independently. The resulting diagrams are very interesting but apparently the user interface is still text-based. Furthermore, the embedded lattice is not faceted, the structure is mainly a tree-hierarchy not a poly-hierarchy, and there is no formal explanation of the query process.

All the current lattice-based retrieval models result in browsing interfaces that rely to a certain degree on manually built structures, in contrast to search interfaces based on automatic classification or clustering. Automated retrieval mechanisms as employed in vector space retrieval systems can be applied to lattices if the notions of similarity measure and distance are transferred to lattices. Lengnink (2000) proposes methods of achieving such measures but so far they have not been applied to information retrieval.

2 The information retrieval system FaIR

2.1 An overview of FaIR and its application domain

FaIR is a lattice-based faceted information retrieval system. Before the elements of the system are described, it should be noted that the examples in the following sections

are taken from an interface prototype of the Indiana University UITS knowledge base KB (UITS, 1999). The KB is an on-line collection of about 5000 FAQ documents of computing questions. Every document covers one question, such as "How do I convert between Unix and DOS text files?" with brief explanations and cross-references to related documents. The KB has two interfaces: a hierarchical menu interface and a Boolean search interface. The prototype described in this paper is based on the search interface. The KB was chosen for this study because its document collection is restricted to a well defined domain and fairly homogeneous. The full-text of the documents is automatically indexed by the KB and the query results are ranked. Therefore it is assumed that problems with automatic indexing procedures, word ambiguities and synonyms may hinder some searches. The system, FaIR, described in this paper is currently under development. Once it is established a usability study will be performed to compare the Boolean search interface with the new lattice-based retrieval interface.

FaIR consists of a faceted thesaurus T/F, a set C of concepts that are generated from the thesaurus and a query language Q that is created from concepts and Boolean operators and that is mapped onto sets of concepts using a mapping $L : Q \to \mathcal{PC}$ where $\mathcal{PC}$ denotes the power set of C. Figure 2 provides an overview of FaIR's components and mappings, which are formally described in the rest of this paper. Documents are represented via a set D of document descriptions that are mapped onto the concepts by a mapping $I : D \to C$. The query language of users is denoted by U and is mapped via $R : U \to Q$ onto the query language Q. The mnemonic for the mappings I, R, L is that I is part of the indexing process, R is part of the retrieval process and L represents the logic of the system. The distinction between query set, document descriptions and thesaurus terms (or concepts) and the mappings in between is based on Salton's (1968) ideas and has been used in many systems since then. On the other hand, FaIR is distinguished from other systems by its use of a lattice-based faceted thesaurus to generate the concepts and the query language. The graphical representation of FaIR is influenced by TOSCANA (Kollewe et al., 1995), but TOSCANA has not been used for faceted thesauri so far and its display mechanism is different. Therefore, to our knowledge the combination of a lattice-based faceted thesaurus with Boolean queries as described in this paper is a new approach to visualizing information retrieval.

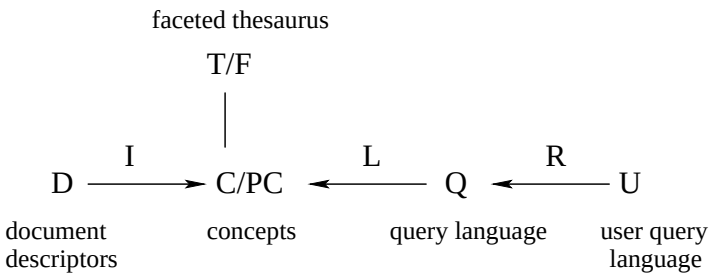

Fig. 2. The elements of FaIR

2.2 Mapping document descriptors onto thesaurus concepts

The faceted thesaurus in FaIR consists of a set T of terms that are partitioned into a set F of facets which are lattices. Figure 3 shows an example of two facets. In the left lattice, ”multi-purpose programming language” and ”WWW programming language” have ”programming language” as join and ”Java” as meet. The bottom nodes of the lattices, the meet of all terms in the lattices, are omitted because they are usually meaningless. Every node in a lattice corresponds to a term, which can be a word or a phrase. For single facets, every term (or node) also corresponds to a concept. Compare Priss & Jacob (1999) for further details on the faceted thesaurus formalism used in FaIR.

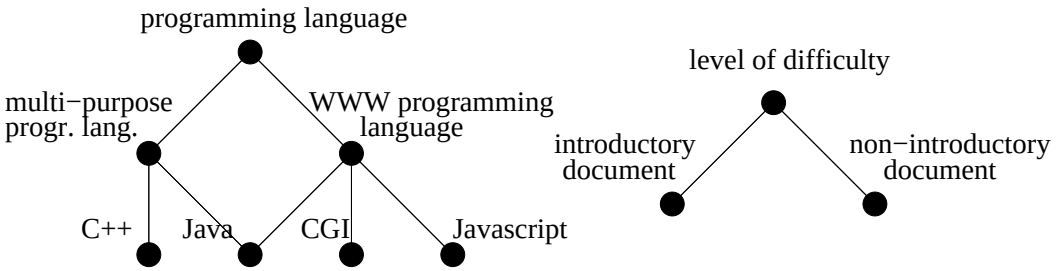

Fig. 3. Two thesaurus facets

For indexing documents, terms from different facets can be combined, such as ”introductory document” and ”Java”. This term composition, which is similar to ”terms with links” (Soergel, 1967), leads to the formation of complex concepts. The set C of concepts consists of simple concepts (single terms from single facets) and complex concepts (term compositions of terms from different facets). Terms within one facet cannot be combined to form concepts because it is assumed that every facet is conceptually complete which means that all necessary combinations are enumerated in the facet. This is not a limitation because facets are restricted to a single viewpoint and are usually small and therefore easy to complete. Ideally the documents are indexed using the concepts of the thesaurus, which means $I : D \rightarrow C$ is a one-to-one mapping. It should be noted that this does not mean that documents are indexed by only one term per document but instead that they are indexed by as many terms as needed but at most one term per facet. If the documents are indexed using a different controlled vocabulary, I is a many-to-one mapping and is implemented as a database table that assigns a concept for each document descriptor. If the documents are indexed without a controlled vocabulary or the vocabulary is unknown before retrieving the documents, such as for documents retrieved from the web, I is implemented as a rule set that maps the document descriptors to concepts based on heuristics and/or natural language processing techniques. The rule set that is chosen for I can vary among applications but it is important that it corresponds to L because the performance of the system depends on the appropriate choice of these two mappings.

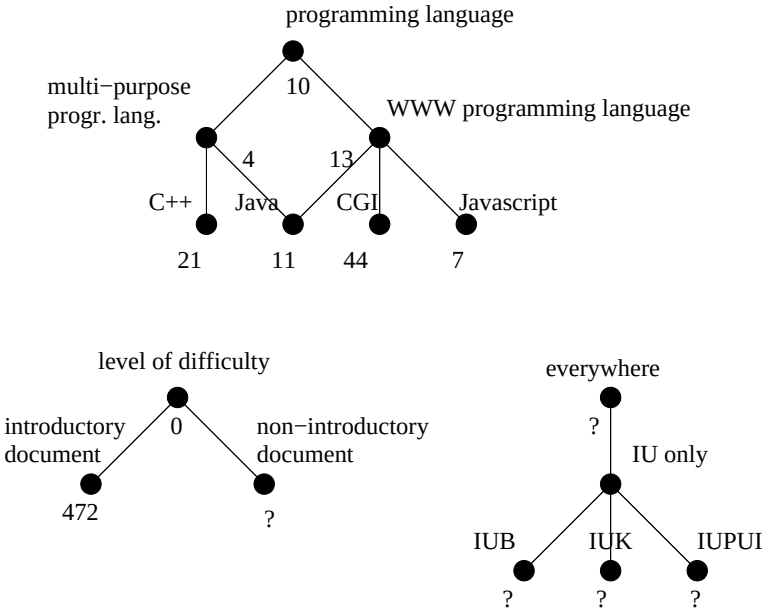

Fig. 4. Thesaurus facets with assigned documents

Figure 4 shows an example of documents of the UITS knowledge base mapped to concepts. The numbers indicate how many documents belong to each concept. A question mark indicates that the number of documents on the concept cannot be determined because of limitations of the current KB interface or that the number of documents is very large (larger than 1000). The facet ”location” (”everywhere” etc) corresponds to a feature of the current KB interface: for every document it is determined whether it is relevant for a general computer community (everywhere) or only for Indiana University (IU only) or for a specific campus (IUB, IUK, IUPUI). This information can only be obtained in combination with a specific topic not with an empty query string hence the question marks. The following rules are used for the mapping I in this application:

- The facets are processed separately.
- A list of synonyms of the terms has been compiled. For the first facet (programming language), only the listed terms are used. For the second facet (level of difficulty), a phrase ”What is” or ”What are” is used as synonym to ”introductory document” because introductory documents in the KB commonly have titles such as ”What is Java”. For the third facet (location), no synonyms are compiled, instead the ”advanced search feature” of the current KB interface is used.
- Documents that contain only one of the terms (or its synonyms) of a facet are mapped to the corresponding concept. This is implemented as a Boolean query for every bottom level concept, such as ”CGI AND NOT (Java OR Javascript OR C++)”.)
- Documents that contain several terms of a facet are mapped to the join of the concepts with the exception that if a document contains both a specific and a general

term, the general term is ignored (see below). This is implemented as Boolean queries for the higher level concepts of each facet, such as ”((CGI AND Javascript) OR (Java AND CGI) OR (Java AND Javascript) OR ”WWW programming language”) AND NOT C++”.)

As an example of the rules, a document on CGI and Javascript (only) is assigned to ”WWW programming language” which is the join of ”CGI” and ”Javascript”. A document on Javascript and Java is also assigned to ”WWW programming language”. The facets of the thesaurus need to be designed carefully so that not too many documents with different descriptors are assigned to the same concept. With respect to the KB, it is not useful to have a concept for the combination of only Java and Javascript under ”WWW programming language”. But for other applications such a concept might be useful. A document that contains ”programming language” and ”Java” but no other terms from the facet is mapped to ”Java”. The more general term ”programming language” is ignored because the document descriptors were derived by full text indexing and many documents start with sentences such as ”Java is a programming language”. Therefore, in this application the more general term often does not add as much information to the document content as the more specific term. In a different application, the rules for mapping descriptors to concepts might be different. For example, manually indexing a document with ”Java” and ”programming language” could indicate that the document is about programming languages in general and uses Java only as an example. This shows that the rules for mapping descriptors to concepts should be formulated only after a careful analysis of the indexing process of the domain.

In this application the documents are assigned to concepts by executing Boolean queries in the current KB interface. A more efficient implementation would pre-process the facets by mapping all documents to the appropriate concepts and then storing document identifiers and concept identifiers in a relational database. The actual numbers would then be produced by issuing an SQL query for each concept. The document counts are only used as an example. Instead of the document numbers, document titles can be displayed. Or the document titles can be retrieved by clicking on the numbers.

Technically every document is mapped onto a single concept not only concerning one facet but concerning all facets. If a document has several descriptors, the descriptors that belong to one facet are mapped onto a single concept in that facet. The concepts of different facets are combined in complex concepts. It follows that although each term belongs to exactly one facet, document descriptors belong to several facets if they represent complex concepts. In that case terms from different facets can have the same synonym. Homographic descriptors must be disambiguated to identify the appropriate facets. This can be done by using natural language processing software or by employing the thesaurus itself for disambiguation by identifying the higher level facets to which a document is mapped. For example, the term ”crane” in a descriptor set {crane, migration, habitat} would point to a different higher level facet than the same term in a set {crane, truck, production}. But word sense disambiguation is a difficult task for any retrieval system and shall not be further discussed in this paper. Concerning the KB, highly ambiguous terms of the domain are stopwords of the system and therefore

ignored in documents and user queries. If a single document, such as a conference proceedings volume, covers a variety of topics and mapping it onto a single concept in every facet to which it belongs is not appropriate because the document covers a variety of terms from single facets, the document should be represented as a set of documents which should be indexed separately. But again that is a strategy that applies to any information retrieval system.

2.3 The query language

The query language Q of FaIR is defined as the set C of concepts together with the Boolean operators AND, OR and NOT, i.e. $Q := (C, \text{AND, OR, NOT})$. Elements of Q are called query terms. Each query term is mapped onto a set of concepts via $L : Q \rightarrow \mathcal{PC}$ as described below. The system's internal query language Q is to be distinguished from the query language U of the user because users may not know the exact vocabulary of the system. The mapping $R : U \rightarrow Q$ is based on lookup tables for synonyms and possibly natural language software for word sense disambiguation. It faces therefore problems similar to those of the mapping I because in each case an uncontrolled vocabulary is mapped onto a controlled vocabulary. Since FaIR has a graphical interface, users can browse through the list of facets and search for specific terms of Q. If a user chooses the search interface, the computer checks if the query term exists and is unique. For ambiguous terms, that is terms that are stored in the system with parenthetical information, such as "crane (animal)" and "crane (device)", the computer inquires which one was meant by the user. If the query term does not exist, the computer suggests near matches, such as terms that are alphabetically close. With the browsing interface, users have direct access to Q. In that case, if it is ignored that users may not have the same understanding of the meaning of terms in Q as is intended by the designers of the system, the languages U and Q can be assumed to be equivalent in FaIR.

2.4 Intra-facet searches

The mapping $L : Q \rightarrow \mathcal{PC}$ must correspond to I. Since, in this application, I maps documents with several descriptors to their joins, a search for a single term must also retrieve more general terms. The following applies to L in this application: using Soergel's (1967) terminology, "exclusive" and "inclusive" searches are distinguished. An exclusive search retrieves an exact concept. For example, a search for "Java" retrieves only documents on Java alone but not documents on "Java and other programming languages". An inclusive search includes more specific and more general terms because a document on "programming languages in general" might also be relevant for "Java". Formally, an exclusive search for a simple concept retrieves only the documents that are directly attached to that node, or to the concept's nodes in different facets in the case of a complex concept. An inclusive search retrieves all documents that are attached to the concept directly and to nodes below and above the concept. In lattice terminology, an inclusive search retrieves the union of the filter (the nodes above) and the ideal (the nodes below) of a concept. The first example in Figure 5 shows searches for "multipurpose programming language". The dashed line indicates the exclusive search while

the inclusive search is the area within the solid line curve. In FaIR's interface the results are highlighted using different colors. Users do not have to type queries but can construct them by clicking and highlighting.

The Boolean AND as exclusive search in a single facet retrieves meet and join of the terms. The inclusive Boolean AND in a single facet is represented by retrieving the documents of single inclusive searches for every term and intersecting the resulting sets. The second example in Figure 5 shows a search with Boolean AND. In this case exclusive and inclusive search are identical because there are no further concepts above the join and below the meet of the terms. In general, an inclusive search retrieves the filter of the join, the ideal of the meet and in the case of comparable terms the interval in between. It is a feature of FaIR that general and specific terms are included in the Boolean AND because the mapping I assigns, for example, documents on all programming languages to the top node. Therefore documents on multi-purpose and WWW programming languages can be found at the top node and at the "Java" node depending on whether they are general or specialized documents. In other applications, it may be appropriate to use a mapping L that maps Boolean AND only to the meet and (its ideal) but not to the join. These are design decision for the mapping L.

Boolean OR is represented as a union of documents retrieved by searching for the terms separately (compare Figure 5 for an example). In this application, the inclusive OR is represented as the union of inclusive single searches. The exclusive OR restricts that union to elements between the meet and join. The inclusive OR is probably not very useful because it retrieves too many documents. The exclusive OR on the other hand, shows everything that is related to either one of the requested terms but is not too general or too specific.

Boolean NOT corresponds to the set theoretical difference. Exclusive NOT excludes all documents that are in the ideal of the term to be excluded; inclusive NOT excludes documents in filter and ideal of the term.

2.5 Inter-facet searches

So far the Boolean operators have only been applied to single facets. If several facets are included in one query, it does not seem sensible to use OR between facets. For example, while a query for "Java AND introductory document" is reasonable, a query for "Java OR introductory document" does not correspond to a common sense logical construction because natural language "or" assumes a shared attribute between the terms such as in "green or blue" which share "color". Sensibly applied Boolean OR usually corresponds to synonyms, such as in "car OR automobile OR auto", which belong to a single facet. Therefore in this application, only Boolean AND is allowed between different facets. In inter-facet searches the difference between exclusive and inclusive does not apply to the search as a whole. Boolean NOT is also restricted to single facets because otherwise inter-facet OR's might result according to de Morgan's laws. For example, "Java AND NOT 'introductory document' AND (everywhere OR IUB)" is an acceptable query; "NOT (Java AND 'introductory document')" which is equivalent

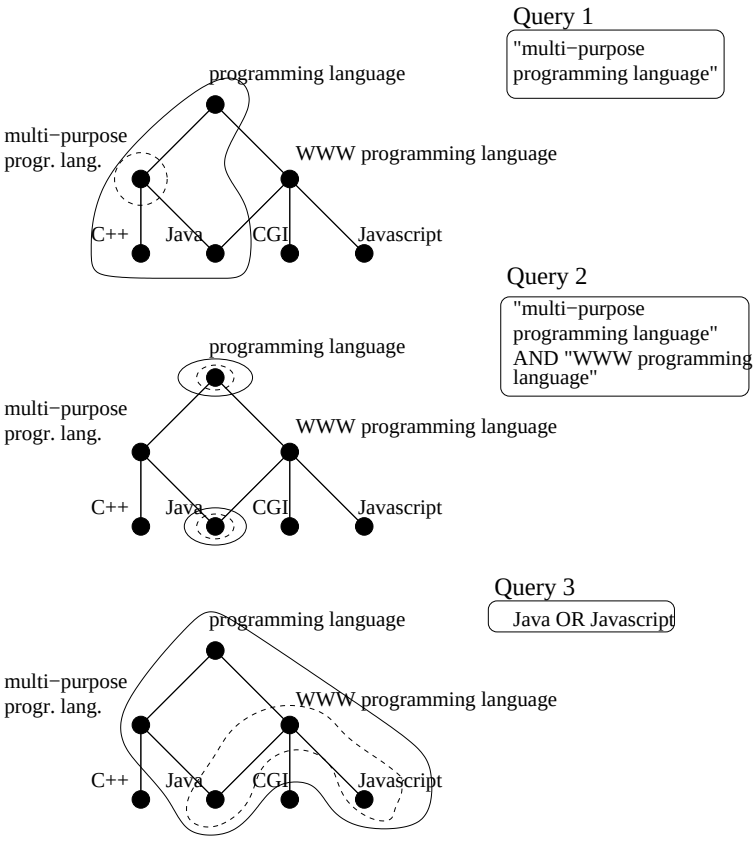

Fig. 5. Several queries in a single facet

to ”NOT Java OR NOT ’introductory document’” is not an acceptable query. As mentioned before, users do not have to worry about these details because they formulate queries by selecting facets and highlighting concepts in these facets.

Figures 6 and 7 demonstrate queries using inter-facet AND. In Figure 6, a user has selected three facets from the KB interface. All terms in all facets are highlighted. This corresponds to inclusive searches for the top nodes of the facets combined by inter-facet AND. The inter-facet AND results in the intersection of the documents of the facets. That means that only the documents that belong to all three facets are counted. In Figure 7, documents on programming languages that are relevant ”everywhere” are selected. Only 65 documents fulfill that condition. The numbers in all three facets are reduced accordingly.

3 Conclusion

An advantage of FaIR is that queries retrieve sets of concepts within the context of conceptual relations. This is in contrast to traditional retrieval systems which show no internal structure of large retrieval sets (except of ranking mechanisms whose functionality is often not clear to the users) or which in the case of an empty retrieval set give no indication as to how the query should be changed to be successful. If too many documents are attached to one node in the retrieval display, users can select additional facets to partition the same set into smaller sets. If no documents are attached to one node, users can identify neighbor nodes that have documents attached. By highlighting certain parts of facets, users can perceive the impact of that selection on related facets and therefore interactively modify the retrieval set until it has an appropriate size. At every point, users have complete control over the system and complete information about the selected facets. Once the result set is small enough, users can click on the document numbers to display document titles, abstracts or the full text of the documents if available.

FaIR’s design is highly modular: the faceted thesaurus is modular in that the facets are conceptually complete and independent of each other. Single facets can be added to or deleted from the thesaurus after an automatic consistency check that assures that terms are not duplicated, links in the facet hierarchy are not missing, and the thesaurus relations are not circular (compare Priss & Jacob (1999)). The thesaurus, set of document descriptors and user query language are connected via mappings. All three can be fairly independent of each other although, if they are totally independent, the system’s efficiency relies heavily on the quality of the mappings. Any faceted thesaurus can be incorporated into FaIR. It follows that users can maintain their own thesaurus as a means of information filtering. In that case users are completely familiar with the query language, i.e. $U = Q$. The only component that might not be totally under user control is the mapping I, although advanced users could change the rules for I manually. The ”black-box phenomenon” of information retrieval systems is thus reduced to natural language processing techniques that can be tested by the user. Users can share their faceted thesaurus or parts of it with other users. They can apply FaIR as a front end to other retrieval systems. It is not suggested that patrons of a library, for example, would be able to use FaIR without some training. The current target user group is

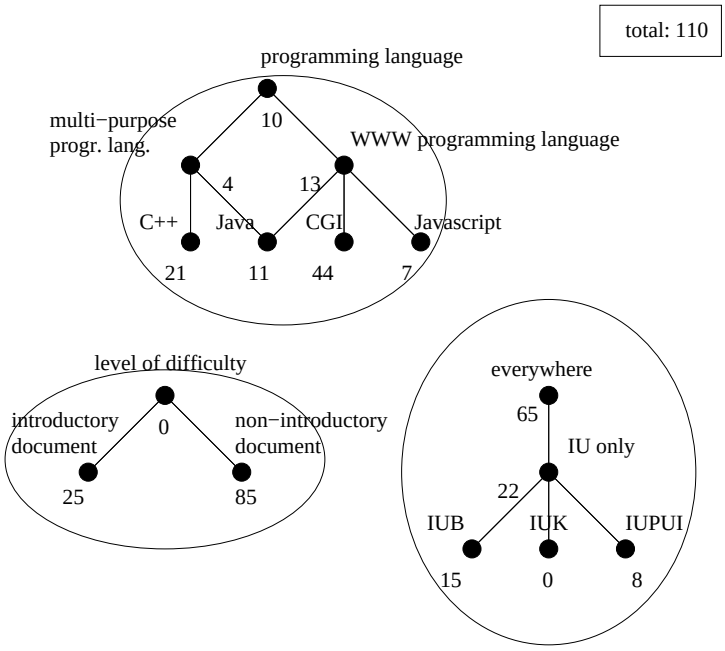

Fig. 6. The query "'programming language' (incl) AND 'everywhere' (incl) AND 'level of difficulty' (incl)"

information professionals that perform queries for patrons and researchers that need to retrieve information concerning a specific domain with high accuracy and convenience and do not mind the effort of learning to use an information retrieval tool.

ABSTRACT

If the number of runs in a (mixed-level) orthogonal array of strength 2 is specified, what numbers of levels and factors are possible?
The collection of possible sets of parameters for orthogonal arrays with N runs has a natural lattice structure,
induced by the ``expansive replacement'' construction method.
In particular the dual atoms in this lattice are the most important parameter sets, since any other parameter set for an N-run orthogonal array can be constructed from them.

To get a sense for the number of dual atoms, and to begin to understand the lattice as a function of N, we investigate the height and the size of the lattice.
It is shown that the height is at most [c(N-1)], where c= 1.4039...
and that there is an infinite sequence of values of N for which this bound is attained.

On the other hand, the number of nodes in the lattice is bounded above by a superpolynomial function of N (and superpolynomial growth does occur for certain sequences of values of N).

Using a new construction based on ``mixed spreads'', all parameter sets with 64 runs are determined. Four of these 64-run orthogonal arrays appear to be new.

Coordination and Shared Mental Models

Diana Richards University of Minnesota

Preferences may be structured by social constraints, by institutional procedures, or, as in the focus of this article, by knowledge representations. This article explores the prospects for successful coordination when players have conflicting preferences but have similar cognitive representations of the decision context. A "knowledge-induced equilibrium" is a stable outcome reached under players' mutual understandings of the empirical context. The purpose of this article is to develop a formal framework that combines strategic rationality with social or cognitive components of knowledge.

Theories of coordination are concerned with how individuals can coordinate their conflicting preferences in the absence of credible communication. Coordination problems abound in politics. For example, voting for a third-party candidate is a coordination problem with other strategic voters (Cox 1997; also Myerson and Weber 1993). The decision to join a risky mass protest (Chong 1991; Lohmann 1994) or to contribute to a public good (Taylor 1987; Ostrom 1990) or to protest a government by withholding tax payments or resisting a military draft (Levi 1988, 1997) are all coordination problems. The establishment of stable institutional arrangements such as norms, conventions, contracts, or principal-agent relationships are also coordination problems (e.g., Axelrod 1986; Spruyt 1994; Young 1998), as are tacit agreements such as restraint in warfare (e.g., Legro 1995) and formal negotiated settlements in conflicts (e.g., Schelling 1960).

However, despite the empirical prevalence of coordination problems, we have failed to achieve a full theoretical account of coordination. The theoretical cul-de-sac arises because coordination problems by definition have multiple equilibria, resulting in indeterminate predictions. The most prevalent solution is Schelling's (1960) idea of a *focal point.* Schelling surmised that coordination could occur if there was some shared interpretation of the salient features of a decision context. Forty years later, the presence of a focal point remains the most frequently invoked concept to explain coordination in politics. However, the concept has largely remained extra-theoretical in that it is seldom formally defined and is typically invoked as a post-hoc explanation of an observed empirical outcome.[1]

There are several different angles from which to develop a more rigorous theory of coordination, most of which include some form of intersubjective understanding among players. One promising solution focuses on the emergence of *precedents and conventions* over time (e.g., Crawford and Haller 1990; Young 1998). However, this solution is most

[1]Experimental studies are an exception to the post-hoc use of a focal point (e.g., Mehta, Starmer, and Sugden 1994; Bacharach and Bernasconi 1997).

American Journal of Political Science, Vol. 45, No. 2, April 2001, Pp. 259–276

applicable to coordination settings where repeated interaction can institutionalize coordination solutions over time, as in long-term economic or social institutions. However, although the folk theorem points out that repeated play can induce cooperation, repeated play can also exacerbate the number of equilibria. Furthermore, coordination in politics often lacks the long-term dynamics that are necessary for evolutionary analysis, as in one-time negotiated settlements to resolve an international disagreement, or voters' coordination on third-party support in a single election, or the decision to walk the town on the Monday evening that became the Leipzig demonstrations in East Germany.

Another approach to coordination looks to the *salience* of particular outcomes resulting from the players' choice of a frame (e.g., Schelling 1960; Sugden 1995; Bacharach and Bernasconi 1997). In this approach, players' strategies are broadened to include not only the coordination act, but also the choice of a payoff-independent labelling scheme that partitions the alternatives into subsets such that one subset is smaller (hence "rarer" and more "salient") by virtue of its feature classification. In these models, unlike traditional game-theoretic models, the labels of the choices matter. For example, Sugden (1995, 549) suggests a labelling scheme based on the extent to which alternatives have been empirically mentioned in the past. Applied to Cox's (1997) multiparty coordination problem, Sugden's model suggests that voters should independently label the small parties in terms of the frequency with which they have been mentioned (such as in the media) and coordinate on the most salient third party under this labelling scheme. However, by treating the labelling of alternatives as independent of players' payoffs, this solution neglects the voters' preferences over parties.

Another approach to coordination focuses on the role of *culture or ideas* as resolving the indeterminacy from multiple equilibria (e.g., Kreps 1991; Ferejohn 1991; Weingast 1995; Schiemann 2000). For example, Kreps (1991) proposes that the presence of a "corporate culture" mediates between actions and outcomes in economic games. Weingast (1995) uses Converse's (1964) idea of a shared system of beliefs to model how a shared understanding of sovereignty maintains international cooperation by removing ambiguity due to differing interpretations about others' actions. Schiemann (2000) discusses the promising gains to be had from merging strategic rationality with intersubjective knowledge, but stops short of providing a formal framework of such a union. Thus, the role of culture or ideas in coordination remains largely at the conceptual stage rather than undertaking the task of developing a formal model of how shared beliefs intersect with players' coordination decisions.

This article develops a formal model of coordination which focuses on the information provided by the participants' mental models. When players have similar mental models of a choice setting, the choices and the relationships between choices have a common underlying structure. This article adapts an equilibrium concept originally developed for social choice (Richards, McKay, and Richards 1998). As in the approaches outlined above, the empirical properties of the alternatives and the intersubjective understandings among players remain important. However, rather than an external labelling scheme that is independent of payoffs, my focus is on the players' internal cognitive representations of the strategy set, which are assumed to be closely coupled with players' preferences. The contribution of this article is to bring together several existing ideas: mental representations from cognitive science, maximum-likelihood from statistics, and coordination games from noncooperative game theory, to develop the concept of a *knowledge-induced equilibrium.*

Shared Mental Models

When the assumption of rationality is relaxed, it is typically to emphasize the limits of humans' abilities to comprehend a complex environment and their need to rely on the use of lower-level algorithmic routines such as myopic searches, satisficing, or mimicking. Clearly there is evidence that these shortcut routines are used by decision makers. However, another way that humans cope with a complex empirical environment is to rely on their powerful mental modeling abilities. These two approaches are both consistent with a rational framework (e.g., Kollman, Miller, and Page 1992; Denzau and North 1994) and can coexist: the former focuses on the implementation of decisions and the latter emphasizes the representation of a decision context. In this article, the emphasis is on the effect of cognitive structures. I refer to the cognitive organization of an empirical domain as a *mental model* and a *knowledge structure* as the representation of a mental model. An organization of knowledge is a *structure* in that it mediates between individuals and their world—much as social constraints or political institutions are also structures (e.g., Converse 1964; Shepsle 1979).

Mental models have diverse organizational form and content. The mental landscape of political parties is a form of a mental model (Poole and Rosenthal 1991;

Hinich and Munger 1994). A mental model may focus on categories and features, as in Clausen's (1973) account of congressional politics. Mental models may also take the form of cause-and-effect models of how the world works and relate to beliefs of what action is appropriate, as in Chamberlin's and Churchill's different causal models and interpretations during World War II. Narratives and stories and plots, like other forms of linguistic communication, are also mental models in that they form a known intrinsic structure in order for the meaning to be understood by the audience. Schemas and analogies are mental models in that they are heuristic narratives that structure understandings of a class of events (e.g., Axelrod 1973; Khong 1992, 25). Mental models organize the empirical world and thus organize interpretations, communication, and behavior.

In this article, a mental model is modeled simplistically with two components: a set of categories and similarity relations among the categories. Specifically, the mental model is represented as a graph, where each node is a category and a link between two nodes indicates that the two categories are closely related in a player's mental organization. Categories that are not adjacent are more cognitively distinct in a player's mental organization. This graph is referred to as the knowledge structure, as it is a representation of players' mental models. It is important to emphasize that this is a "feature-based" rather than exclusively metric representation (Tversky 1977).

Example 1 *Organization of Political Parties*

One way to organize political parties is to place them on a left-right continuum. Traditionally this organization is modeled spatially (e.g., Downs 1957; Black 1958; Hinich and Munger 1994). A more general nonmetric cognitive organization would allow voters to have a mental map of the set of political parties, such as that the Green Party is similar to the Citizen Party and more similar to the Democratic Party than to the Republican Party. ■

Example 2 *Organization of Proposals under Negotiation*

Negotiation can take place over relatively trivial categories, such as how to spend the evening in the battle-of-the-sexes game, or over categories with profound historical impact, such as which set of institutional rules to implement as a framework for governing the United States, or which armistice agreement to abide by during World War I. Whatever the content of the negotiation, participants organize the set of proposals comparatively in a mental framework in order to understand their relative merits. For example, in the 1787 Convention, where collections of institutional rules such as the Nationalist Plan or the Federalist Plan were debated, much of the debate among the delegates centered on organizing the similarity and differences between the various plans. ■

Example 3 *A Knowledge Representation of Political Organizations*

Ideology itself is an organization of knowledge in that it summarizes relationships between political ideas. Using data from a larger experimental study, Figure 1 summarizes how a group of fifteen students collectively organized fourteen American political organizations.[2] Each student completed a survey on how he or she organized the categories both in terms of similarity and in terms of adjacency triples.[3] The data were analyzed to identify statistically significant pairs and triples of categories across all the subjects' responses. Figure 1 shows a simplified version of the results of these multidimensional scaling techniques. Each node is a category and each edge is a statistically significant similarity relation between those two categories based on the students' pooled data. For example, the radical environmental group Earthfirst! was placed adjacent to Greenpeace and PETA, but not directly adjacent to the moderate Sierra Club. The American Civil Liberties Union was placed as similar to organizations both on the traditional right, such as the National Rifle Association (advocating the right to bear arms) and the traditional left, such as the National Organization for the Reform of Marijuana Laws (advocating the legalization of marijuana).[4] ■

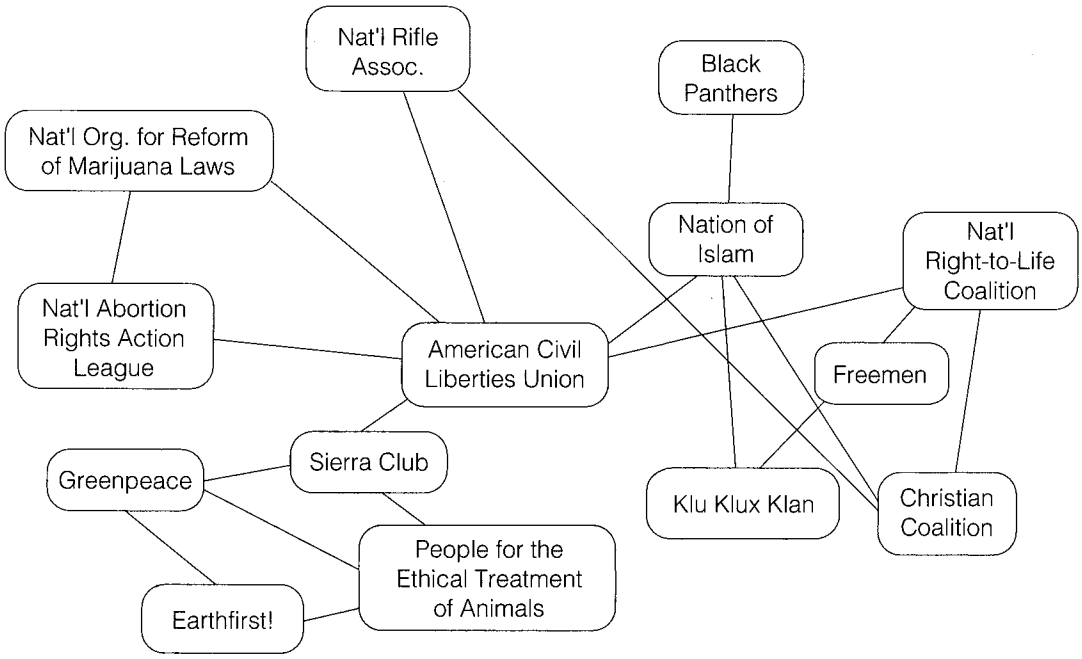
In the formal model presented below, I assume that mental models are shared across decision makers. The idea of shared knowledge is not new in political science. Philip Converse's work (1964) emphasized the role of a shared system of beliefs in politics. Thomas Schelling's (1960) focal point solution is basically an appeal to intersubjective or cultural understandings. Both recent constructivist approaches and studies of epistemic communities in international relations emphasize the importance of collective knowledge (e.g., Wendt 1999; Haas

[2] Since the data for this example is part of a larger experimental project, details on the experimental protocol are not given. However, standard experimental techniques were used, including the independent creation of the list of categories (based on a separate survey asking for salient contemporary political organizations), randomization of survey questions, anonymity of subjects' responses, and compensation for subjects' time.

[3] These triples are called "trajectories" in a mental representation. The procedure is described in Richards and Koenderink (1995).

[4] This example illustrates a knowledge structure as a graph of categories and similarity relationships but should be not be interpreted as a coordination example.

FIGURE 1 Graph Representation of Knowledge: Experimental Data on Political Organizations



All edges shown are significant at .01 level based on multinomial distribution of pooled data on adjacency triples from 15 subjects (n = 210). Lengths of edges are irrelevant (although the spatial layout of the categories is guided by multidimensional scaling on subjects' pooled responses on the pairwise similarity of the categories.

1990). Within the formal literature, the Condorcet Jury Theorem implicitly includes shared knowledge in the common value assumption of a shared probability of choosing correctly (e.g., Miller 1986; Austen-Smith and Banks 1996). Some evidence of shared knowledge from other fields includes the shared linguistic structure of grammar and phonetics, the common semantic structure of kinship terms (Romney et al. 1996), perceptual saliency in cognitive science where humans all pick the same key features when shown an empirical context (Ullman 1996), and shared reciprocity relations (Cosmides and Tooby 1992; Richards 2001).

However, the extent to which knowledge is shared is an important empirical question. Certainly many beliefs and ideas vary greatly across individuals due to differences in socioeconomic position, information access, culture, or experience (e.g., Wittkopf and Maggioto 1983; Conover and Feldman 1984). The extent to which mental models are shared, in terms of agreement over categories and relationships, is a potentially important independent variable. Political disagreement may stem from differences in preferences or from different conceptions of basic category relations. The variation in the extent to which models are shared may be manifested across issues (as in the disagreement over basic category relations in the debate over affirmative action) or across subgroups (such as between elites and masses [Converse 1964]). The purpose of this article, like that of Shepsle's (1979) insights regarding institutional structures, is to demonstrate that knowledge structures, when shared, are a source of stability in collective decision making.

Organizing Outcomes in Coordination Games: Two Examples

In *coordination* or *bargaining games,* players have a common interest in reaching some agreement but have different preferences over the terms of agreement and are often uncertain of other players' preferences. Two classic representations of coordination problems are the battle-of-the-sexes game (Luce and Raiffa 1985, 91; Banks and Calvert 1992) and Schelling's parachutist game (Schelling 1960, 58–59; Gauthier 1975; Sugden 1995). In this section I explore these two classic examples through the perspective of players placing an organizational structure on the choice context with shared mental models.

Battle-of-the-Sexes

In the traditional narrative of the battle-of-the-sexes game, two players must coordinate on one activity for the evening, such as between a prize fight and a ballet, where the players disagree over the ranking of the activities, but prefer to go to any activity with the other than to spend the evening alone. Thus, players face multiple equilibria and the danger that if they fail to coordinate at one of the equilibrium outcomes the result will be inferior. This game has been used to model bargaining and repeated Prisoners' Dilemma games (Schelling 1960; Hardin 1982; Taylor 1987). The traditional solution to the game is the mixed-strategy equilibrium, the only symmetric equilibrium of the game, where players randomize over their choices of the evening's activities. Recent extensions also consider the role of communication (e.g., Banks and Calvert 1992).

In this example I consider the contribution of players' mental models. Communication and repeated play is removed in this example to illustrate the role of knowledge structures. Elaborating on Luce and Raiffa's original story, suppose that a couple arranged to meet at "Cinema One-2-Many" to watch a film but they did not decide which film to watch. Upon arriving a few minutes late to the cinema, each player quickly scans the list of current showings: an adventure film, a comedy, a drama, a mystery, a suspense thriller, and a war movie. Each person has their own private preferences for the evening's film but prefers watching any movie with the other person to watching their top-ranked choice alone. Assume that neither person knows the other person's preferences for that evening's film. Which film should they choose?

Film genres, like other forms of narrative, are organized using mental models derived from an understanding of the attributes of the film categories. For example, categories of films differ in their mood, level of violence, and tension in the plot. Assume that prior to any coordination choice, players cognitively organize these outcomes in a mental map. This mental map allows each player to understand what it means to say that a film is a "suspense thriller" and informs that player's preference formation. I begin by assuming that the basic organization of the outcomes is shared, namely that although players may disagree over their rankings of the film genres, they both organize them in the same abstract cognitive arrangements. Figure 2 shows a shared organization of the film genres from a larger experimental study.[5]

[5] This graph is an excerpt from more detailed experimental tests conducted with Whitman Richards using multidimensional scaling techniques.

The formal model described in detail in the following section assumes that players' preferences over the coordination equilibria follow from their organization of the empirical context. In other words, the knowledge structure is assumed to contain information about feasible and consistent preferences. Let $\succ$ denote preference between two actions and $\sim$ denote indifference. If player 1 most prefers watching the drama, then her preferences over the remaining outcomes are assumed to follow from her organization of the activities: drama $\succ$ comedy $\sim$ adventure $\sim$ mystery $\succ$ suspense $\sim$ war. The assumptions of the model imply six preference orderings over outcomes consistent with the knowledge structure of Figure 2:

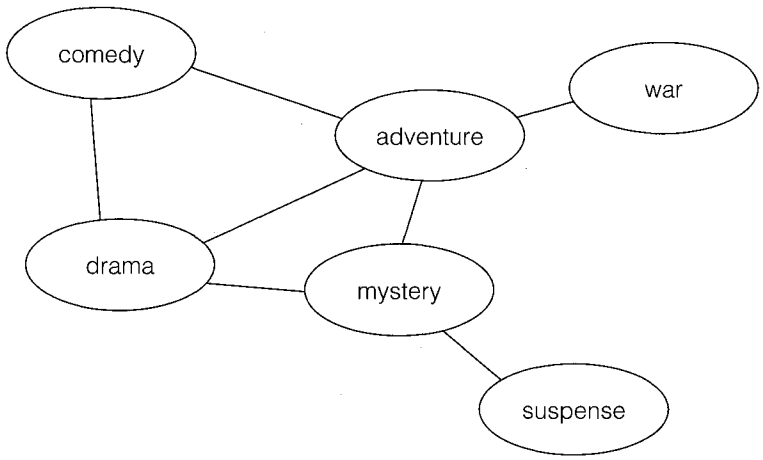
$$\begin{aligned}
\tau_a &\equiv \text{adventure} \succ \text{war} \sim \text{mystery} \sim \text{drama} \sim \text{comedy} \succ \text{suspense},\\
\tau_c &\equiv \text{comedy} \succ \text{adventure} \sim \text{drama} \succ \text{mystery} \sim \text{war} \succ \text{suspense},\\
\tau_d &\equiv \text{drama} \succ \text{comedy} \sim \text{adventure} \sim \text{mystery} \succ \text{suspense} \sim \text{war},\\
\tau_m &\equiv \text{mystery} \succ \text{suspense} \sim \text{adventure} \sim \text{drama} \succ \text{comedy} \sim \text{war},\\
\tau_s &\equiv \text{suspense} \succ \text{mystery} \succ \text{adventure} \sim \text{drama} \succ \text{comedy} \sim \text{war},\\
\tau_w &\equiv \text{war} \succ \text{adventure} \succ \text{comedy} \sim \text{drama} \sim \text{mystery} \succ \text{suspense}. \qquad (1)
\end{aligned}$$

The important theoretical point is that each player's mental model is a structure that organizes preferences. Players can use the information embedded in this structure to collectively maximize the probability of coordination. Specifically, given shared mental models, agents can use a maximum-likelihood rule for determining which alternative beats all other alternatives in a particular choice context. Later it will be shown formally that this alternative is the action that is highest ranked over the distribution of preference types; furthermore, this alternative very often can be identified using a simple heuristic from the knowledge structure.

Assume for simplicity that players' preferences are distributed uniformly over the m ideal points and let the cost function simply be the path length in Figure 2 from a player's ideal point to that action. Then the sum of the rankings of each action from the orderings in (1) are:

$$\begin{aligned}
\text{adventure}: &\ 0+1+1+1+2+1=6,\\
\text{comedy}: &\ 1+0+1+2+3+2=9,\\
\text{drama}: &\ 1+1+0+1+2+2=7,\\
\text{mystery}: &\ 1+2+1+0+1+2=7,\\
\text{suspense}: &\ 2+3+2+1+0+3=11,\\
\text{war}: &\ 1+2+2+2+3+0=10. \qquad (2)
\end{aligned}$$

FIGURE 2 Shared Mental Map of the Film Genre



Adventure-mystery edge significant at .10 level; all other edges significant at .01 level.

From the expressions in (2), the activity with the lowest sum is the activity that is highest ranked over all preferences induced from organization of outcomes, which in this case is the adventure film. The outcome "meet in the adventure film theatre" is defined here as a knowledge-induced equilibrium. This outcome is the alternative that beats all other alternatives in this choice context using a maximum-likelihood rule.

Schelling's Parachutist Game

The logic outlined above also applies to games with incomplete information and to games with more than two players. To illustrate, consider Schelling's Parachutist Game extended to three players. Three parachutists each have a choice of m strategies, namely where to walk to meet the other parachutists (Figure 3a). Each player wants to reduce his costs of walking (by meeting at the location closest to his landing site) but will not receive the positive benefit of meeting unless all players coordinate on the same location. (It is assumed that players are unable to credibly communicate.) Each player knows the set of meeting places and is only informed about his own location and preferences over meeting places (referred to as a player's "type"). These informational conditions, as well as the distribution over players types, are common knowledge. Unfortunately, there are multiple Bayesian Nash equilibria in this game and players' preferences over these equilibria are in conflict.

If players form a mental map of the decision context, then it might look like that in Figure 3b, where players identify salient features of the landscape and connect these features based on empirical knowledge (such as that water runs downhill, bridges cross rivers, and farms are accessed by roads).[6] Players' preferences are assumed to be consistent with the empirical organization of the decision context. Assume in this case that the probability distribution over players' types (tributary, bridge, pond, road, driveway, farmhouse) is (.1,.3,.1,.3,.1,.1). Players know this aggregate information, although they do not know where particular other players land, because they have shared information about factors that affect where each might land, such as the topography or wind conditions. Then the outcome "players of all types meet at the road junction," with minimum weighted sum of rankings $(.1) \cdot 2 + (.3) \cdot 1 + (.1) \cdot 1 + (.3) \cdot 0 + (.1) \cdot 1 + (.1) \cdot 2 = .9$, is the outcome that beats all other outcomes in this choice context using a maximum-likelihood rule. This outcome is a Bayesian Nash equilibrium and is the unique prescription of the shared knowledge structure.

The Formal Model

A pure coordination game is a one-shot game with symmetric payoffs and no credible communication between players. The advantage of such stylized constructions of coordination problems (as in Schelling 1960; Gauthier 1975; Sugden 1995) is that they illustrate at its barest the problems of indeterminacy and belief convergence in

[6]Ullman (1996) presents empirical evidence that humans do identify the same key features (referred to as *perceptual saliency*). Evidence of the use of shared knowledge of empirical relations is in Knill and Richards (1996).

FIGURE 3a Map of Parachutists' Bargaining Game

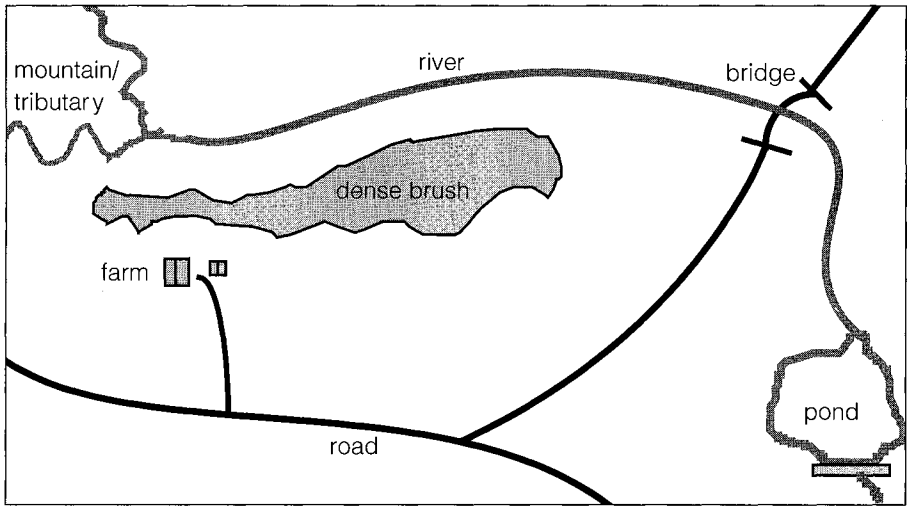


FIGURE 3b Hypothetical Mental Map of Figure 3a

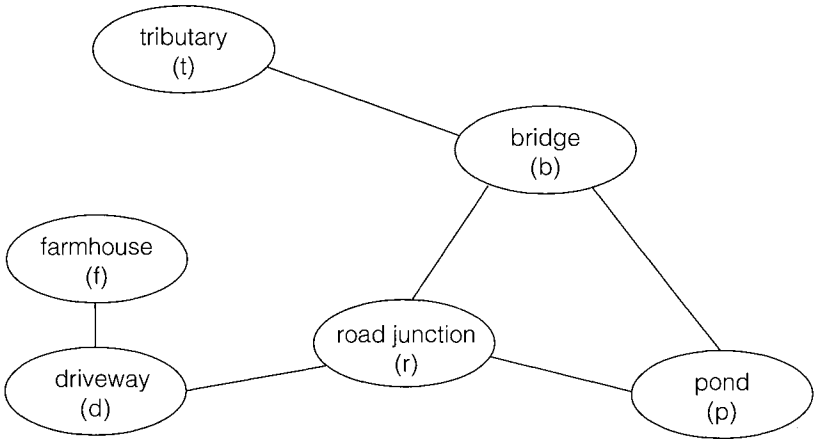


games with multiple equilibria. This construction is empirically artificial, but the effect of shared knowledge structures in this game generalizes to more complicated settings as well.

A *knowledge structure game* Γ consists of a finite set of players, denoted $i = 1,...,n$ and a finite set of actions $A = \{a_1,..., a_m\}$, where each player's action set is symmetric and the set of actions is common knowledge. The set of actions is organized by a *knowledge structure* which is a labeled graph $\mathcal{M}(A,E)$ with vertices A and a set of edges E. A vertex may have one or more edges, but it is assumed that $\mathcal{M}$ is connected.[7] Each edge $e = \{a_j,a_k\}$ of $\mathcal{M}$ linking a_j and a_k corresponds to a similarity link based on the set of features or attributes between actions a_j and a_k. It is assumed that $\mathcal{M}$ is mutual knowledge, i.e., that all players organize the set of actions in the same way (as in Sugden's mutual knowledge about labels [1995, 536]), or more specifically, that a player assigns some probability ρ to the other players organizing the choice set in the same way. This assumption is weaker than common knowledge, which would require that all players know that all other players know that they all organize the choice set in the same way, *ad infinitum.*

In a coordination setting, the organization can also be thought of as an organization over *outcomes* rather than over actions, although the two are related. In a slight abuse of notation, when used to designate an organization over coordination outcomes, the graph will be

[7] The assumption that knowledge structures are connected implies that any feasible alternative in the choice set possesses at least one feature (e.g., Tversky 1977) that allows that alternative to be referentially related to another alternative in the choice set.

denoted as O, where the vertices $a_1,\ldots,a_m$ of O represent coordination by all players at one of the m actions. The game is then referred to in shorthand as $\Gamma(O)$.

It is assumed that players' utility functions over A are consistent with their mental organization of A; thus the organization of outcomes constrains the set of feasible utility functions. This assumption has precedent from a variety of sources. For example, Bacharach (1993) refers to a "first phase of decision making where an agent arrives at some way of describing the options to herself" (see also Gauthier 1975; Nozick 1993, 134–135; Wendt 1992). Many of Anthony Downs's (1957) hypotheses stem from assumptions that preferences are connected to the structure of empirical choices (see also Hinich and Munger 1994). Most similarly, Black's theorem (1958) imposes a requirement that preferences are consistent with a linear ordering of the choice set. Black's assumption of a linear left-right continuum can be extended to the notion of ideological constraint in general, where preferences are constrained by a conceptual organization of the alternatives (e.g., Sullivan, Piereson, and Marcus 1978). Black's theorem can be thought of as the special case where $\mathcal{M}$ is a linear ordering; or conversely, the model presented here can be thought of as a graph-theoretic extension of Black's linear ordering of alternatives with its induced single-peaked preferences.

Specifically, each vertex $a_j \in O$ defines a *type* of player, in the Bayesian sense, who most prefers coordination at outcome a_j and whose preferences over the remaining actions follow from the knowledge structure O. Since utility functions are constrained by O, a player's type is defined by identifying that player's top-ranked outcome or *ideal* point. Players' types (or equivalently, ideal points) occur with a probability distribution $\varnothing$ over A. Players are informed about the probability distribution $\varnothing$ as well as their own type, but are unaware of other players' types.[8] Players make simultaneous choices of an action in A.

The graphs $\mathcal{M}$ and O are assumed to be unweighted, allowing players' utility functions for all m types to be defined by the path lengths through O. (Weighted relationships are straightforward but complicate the description.) Let B denote the positive payoff from successful coordination. Let $\beta(a_j;a_\tau)$ denote the cost to a type τ player (a player with ideal point a_τ) of choosing action a_j. For example, assuming an unweighted graph, $\beta(a_j; a_\tau)$ is equivalent to the number of edges on the shortest path length from ideal point a_τ to action a_j, namely $d(a_j, a_\tau)$. Let a^*_{-i} denote the equilibrium action of all other players except player i. The utility function of player i with ideal point a_τ is

$$u_{i,\tau}(a_j) = \begin{cases} B-\beta(a_j;a_\tau) & \text{if } a_j = a^*_{-i} \\ -\beta(a_j;a_\tau) & \text{if } a_j \neq a^*_{-i} \end{cases} \qquad (3)$$

for $\tau = 1,\ldots,m$. As in the examples above, players receive the benefit B only if they coordinate at the same action yet incur costs $\beta(a_j;a_\tau)$ whether or not they successfully coordinate due to the costs of choosing an action (e.g., Sugden 1995).

The presence of a shared interpretation of the choice environment provides information that allows players to maximize the probability of choosing the action that is top-ranked for all possible preferences. As Young (1986, 1995) shows, if one wants to maximize the probability of getting a correct social ranking over a set of choices, then the Condorcet rule is the "optimal rule."[9] However, in coordination games the full social ranking is unnecessary and one only needs to identify the most-likely top-ranked action. In this case Young shows that the Borda winner, the action that beats the other actions most often in a series, is the optimal rule that yields the maximum-likelihood estimate of the top-ranked alternative.[10] The following example illustrates this logic:

Example 4 *Maximum-likelihood Estimation and Schelling's Bargaining Game*

Consider the Schelling bargaining game of the previous section. In order to simplify the example I will assume that there are two players and that the probability of each type is $1/m$.[11] Since players are unaware of their own type

[8] This assumption is not new to a shared knowledge structure approach. Nearly all models of games of incomplete information assume that the probability distribution is known by the players. The justification is that aggregate information (such as through polls or the media) is more readily available than private, individual preference information.

[9] Young's maximum-likelihood approach applies both to cases where there is an objective true answer (as in the Condorcet Jury Theorem) and where the answer is endogenously derived from voters' preference rankings (e.g., Young 1986).

[10] Note that other maximum-likelihood rules might be appropriate for coordination settings, depending on what is to be maximized. Young's rule maximizes the probability of identifying the single alternative that is most likely to be top-ranked over voters' preferences, which is the fundamental problem of coordination. However, if, for example, robustness is the most important criterion (namely identifying the alternative that is most insensitive to changes in the choice set), then a different maximum-likelihood rule might be derived.

[11] More players requires sampling on a combinatorially larger set, such as *ttt, ttb, ttp, ..., fff* for three players. In general, the distribution of the sampling is proportional to the distribution of players' types $\varnothing$, and the Borda scores are correspondingly weighted by $\varnothing$. For example, with two players and $\varnothing = \left(\frac{1}{2},\frac{1}{2},0,\ldots,0\right)$ the sampling is on *tt, tb, bt,* and *bb,* and the Borda score for r is $\frac{1}{2}\cdot 2+\frac{1}{2}\cdot 1+0\cdot(1+0+1+2)$.

ex ante and players remain unaware of each others' types in the interim, each player must maximize over all possible positions of both players. With two players there are m^2 possible combinations of players' types and $\binom{m}{2}$ pairwise comparisons of the actions. Since players do not have information about each other's type, in effect they are drawing a sample of each pairwise comparison of actions and asking which action has the highest probability of being the winner for all possible combinations of players' types. The action a_j that has the maximum-likelihood of being "best" for all possible player types is the action with the greatest probability of winning against all other $a_k \in A$, $k \neq j$ (Young 1986). In this example, outcome r is the maximum-likelihood winner since the probability that r is best is $\left(24+\frac{1}{2}\cdot 9\right)/36$ against outcome t, $\left(15+\frac{1}{2}\cdot 13\right)/36$ against outcome b, $\left(21+\frac{1}{2}\cdot 10\right)/36$ against outcome p, $\left(16+\frac{1}{2}\cdot 16\right)/36$ against outcome d, and $\left(20+\frac{1}{2}\cdot 13\right)/36$ against outcome f, giving an average probability of $\frac{27.3}{36}$ of being the best coordination outcome (see also Young 1986, 117). Thus, action r has the greatest average probability of being best; the next best action is b with an average probability of $\frac{22.5}{36}$ and the action with the lowest average probability of being best is f with an average probability of $\frac{10.4}{36}$.[12] ■

This tedious sampling approach illustrates the connection to maximum-likelihood estimation but is unnecessary since Young (1986, 1988, 1995) shows the equivalency between this procedure and the much simpler procedure of choosing the action with the lowest Borda score (see appendix). Using this shortcut (which is independent of the number of players but not independent of the distribution of types), the outcome r is quickly identified as the maximum-likelihood winner since it has the minimum Borda score (or equivalently, is highest ranked over all types). However, to implement a decision based on the knowledge structure, agents need not engage in any calculations at all but can rely on a simple heuristic: in most cases, the maximum-likelihood winner (or equivalently the Borda winner) is the alternative in the knowledge structure $\mathcal{M}$ with maximum degree, namely the alternative that is adjacent to the greatest number of other alternatives in the choice set. Specifically, for random graphs and random distributions of players' types, the probability that an alternative that is the Borda winner is also an alternative with maximum degree is approximately .75 for choice sets up to ten alternatives.[13]

We can now precisely define a knowledge-induced equilibrium in a coordination game Γ with shared knowledge structure O:

Lemma 1 An action $a_j \in A$ is the Borda winner *iff* a_j is $\arg\min \sum_{a_k \in A} d(a_j, a_k)$

Proof. By the utility functions of Equation (3), the players' rankings over the outcomes $a_j \in O$ correspond to the distance from a_j to the ideal point for that player's type. The Borda winner is the action that is highest ranked over all players' types, which corresponds to the action with the lowest sum of distances to all ideal points, namely the a_j that minimizes $\sum_{a_\tau \in A} \beta(a_j; a_\tau)$. By the definition of $\beta(a_j; a_\tau)$ this is equivalent to the a_j that minimizes $\sum_{a_k \in A} d(a_j, a_k)$.[14] ■

Definition 1 *An outcome* a_j^* *is a* knowledge-induced equilibrium *of* $\Gamma(O)$ *iff* a_j^* *is* $\arg\min \sum_{a_k \in O} d(a_j^*, a_k)$.

Results

A knowledge-induced equilibrium can be thought of as a refinement to the set of (Bayesian) Nash equilibria for games where players share an organization of the action set. This section presents some general properties and results of a knowledge-induced equilibrium. Until the

[12] To recreate these values, make a 36 × 15 table where the rows are all combinations of players' types: *tt*, *tb*, *tp*, ..., *ff*, and the columns are the pairwise comparisons: *t* versus *b*, *t* versus *p*, ..., *d* versus *f*. For each cell, enter the action that is the winner in that pairwise comparison given that distribution of players' types and their utility functions. If two actions a_j and a_k are tied then each is best with probability 1/2 in that cell. The probability that t is best against *b* is the total number of times in the 36 rows that *t* beats *b* plus one-half the number of times *t* ties *b*.

[13] This result is based on simulations with random graphs (probability of an edge = .5) and random distributions of agents ($\varnothing$) over the feasible preference types for m = 3,...,10,15, 20 with 1000 trials each. Even for choice sets as large as twenty alternatives, the Borda winner is the vertex with maximum degree in nearly two-thirds of the cases (.63) and was nearly always the vertex with either the maximum or one less than the maximum degree.

[14] Note that the maximum-likelihood winner is not equivalent to two common graph-theoretic definitions of centrality: the *center* (the vertex with minimum eccentricity) and the *centroid* of a graph (defined only for trees as the vertex with the minimum-maximum branch weight). Examples are easy to construct where the concepts do not coincide.

relaxation of this assumption in Propositions 6 and 7, it is assumed that the knowledge structure is shared.

Theorem 2 *A coordination game $\Gamma(O)$ has at least one knowledge-induced equilibrium.*

Proof. For any graph O, there is always at least one vertex a_j^* for which a_j^* is arg $\min \sum_{a_k \in O} d(a_j^*, a_k)$. ■

Corollary 3 *If a_j^* is a knowledge-induced equilibrium, then a_j^* is a (Bayesian) Nash equilibrium.*

Proof. In the construction of the coordination game $\Gamma(O)$, the graph O consists of the m coordination outcomes, each of which is a Nash equilibrium of the coordination game. A knowledge-induced equilibrium is a subset of the coordination outcomes of O. Given that players coordinate at a_j^*, they have no incentive to unilaterally deviate from their equilibrium action. ■

A knowledge-induced equilibrium is also a coalition-proof Nash equilibrium, as shown by the following corollary, implying that it is an efficient, self-enforcing agreement under nonbinding preplay communication (Bernheim et al. 1987).

Corollary 4 *A unique knowledge-induced equilibrium is a strong Nash equilibrium.*

Proof. Since coordination requires the choice of the same action by all players, unilateral changes of strategies by any coalition of players results in a lower payoff for at least one member of the coalition. ■

The force of the knowledge structure is to organize and restrict the set of players' preferences in particular consistent ways, thereby allowing for a maximum-likelihood winner to emerge (e.g., Saari 1994; Richards, McKay, and Richards 1998). As in other structural restrictions (e.g., Shepsle 1979; Black 1958), the knowledge structure contains implicit information because it constrains the extent of feasible preference types. To illustrate the force of this structure, the following simple (and familiar) example highlights how a collection of preferences not structured by a knowledge representation yields to a breakdown of a maximum-likelihood winner.

Example 5 *Preferences not consistent with a common knowledge structure.*

Assume three preference types: $a \succ b \succ c, b \succ c \succ a$, and $c \succ a \succ b$ that do not form a consistent shared $\mathcal{M}$. Using the procedure of Young (1986), the probability that a is best against b is 6/9 and the probability that a is best against c is 3/9. Similarly, the probability that b is best against c is 6/9 and the probability that c is best against a is 6/9, yielding the intransitive information that a is likely to be better than b, c is likely to be better than a, and b is likely to be better than c. The average probability that any alternative is best is .5 for a, b, and c, yielding no maximum-likelihood winner. ■

Uniqueness of Knowledge-Induced Equilibria

In any coordination setting, uniqueness is a virtue. However, it is already apparent that a knowledge-induced equilibrium need not be unique since a graph O may have multiple vertices that minimize $\sum_{a_k=1}^{m} d(a_j^*, a_k)$. Thus, like other coordination prescriptions (e.g., Sugden 1995), a knowledge-induced equilibrium will provide guidance in some cases, but not in others. Before presenting the positive results, I illustrate some of the worst-case scenarios with examples.

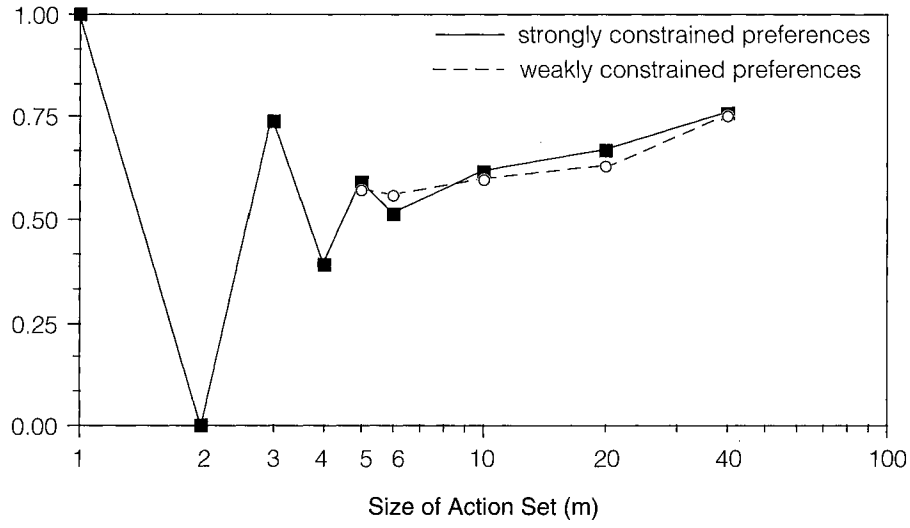
The set of equilibria need not be adjacent in O. For example, if O has edges $E = (a_1a_3, a_1a_5, a_2a_3, a_2a_5, a_3a_4, a_4a_5)$ then the outcomes a_3 and a_5 are both knowledge-induced equilibria but a_3 is not adjacent to a_5. Multiple knowledge-induced equilibria occur when O is symmetric and can potentially include the entire set of actions in nongeneric symmetric cases. Let O be a ring graph R_m. Then there are m knowledge-induced equilibria. It might be conjectured that the cardinality of the set of knowledge-induced equilibria depends solely on the symmetry of the knowledge structure. This is not true. Although the symmetry of the structure plays a role, it is not a perfect predictor, as the following example shows: if O has edges $E = (a_1a_2, a_2a_3, a_2a_6, a_3a_4, a_3a_5, a_4a_5, a_5a_6)$ then O is asymmetric but $\Gamma(O)$ has two knowledge-induced equilibria: outcomes a_2 and a_3.

However, particular forms of knowledge structures do lead to specific properties of the set of knowledge-induced equilibria. An empirically prevalent representational form is a *tree*, as in the taxonomy of animal species, kinship networks, or a city-block ideology metric (e.g., Minsky 1985; Corter 1996; Barberà, Gul, and Stacchetti 1993). The following theorem shows that if the knowledge structure is a tree (a connected acyclic graph), then the set of knowledge-induced equilibria consists of at most two adjacent equilibria. This implies that knowledge representations of these common forms will have special (and nice) coordination properties.

Theorem 5 *If O is a tree then $\Gamma(O)$ has at most two knowledge-induced equilibria and they will be adjacent in O.*

Proof. See appendix.

FIGURE 4 Probability of a Unique Knowledge-Induced Equilibrium



Examples are useful to illustrate the possibilities of uniqueness and its failures; however, to explore the question of how often a knowledge-structure game prescribes a unique equilibrium we need to turn to Monte Carlo simulations. The procedure is to generate random graphs with m vertices and estimate the percent of graphs which prescribe a unique equilibrium in a knowledge-structure graph. Each graph is a random (connected) graph with the probability of an edge equal to $\frac{1}{2}$, which corresponds to sampling uniformly from all labelled graphs on m vertices and which generates the greatest variety of nonisomorphic graphs for any fixed-edge probability and number of vertices.[15] Figure 4 summarizes the results. (Note the log scale.) There are several interesting observations. First, although a knowledge-structure game may have multiple equilibria, this is not the norm based on an examination of the set of random graphs. Obviously three-quarters of all knowledge structures with a choice set of three actions prescribe a unique equilibrium. Less intuitively, choice sets with five or six actions also have a probability of .5 or better of a unique equilibrium. However, a second observation is that some choice sets are clearly worse than others: most notable in this category are the cases with $m = 2$ and $m = 4$. The symmetry effects of even-versus-odd choice sets create drastic oscillation of the probability results for small choice sets, but disappears as m increases. Third, and probably most surprising, the prospects for a unique equilibrium *improve* rather than decline as the size of the choice set increases. Even for choice sets that are extremely large by empirical standards, such as $m = 40$, the probability of a unique equilibrium prescription in a knowledge-structure game is still approximately .75. Furthermore, the assumption that preferences are perfectly consistent with the knowledge structure can be relaxed in various ways. Similar results hold if players' preferences are structured by $\mathcal{M}$ only over a subset of vertices near an agent's ideal point (with indifference thereafter) rather than over the entire choice set. The dashed line in Figure 4 shows the case where preferences are constrained only within two edge steps from each agent's ideal point.

[15] Five hundred graphs were generated for cases with m 20. One hundred graphs were generated for the forty-vertex case. Only 100 trials were run for $m = 40$ because a single trial took thirty minutes of computer time. To verify the accuracy of the Monte Carlo simulations, the program was also run on the complete set of all connected graphs for $m = 3, 4, 5$, and 6 (from the appendix in Harary 1969).

Uncertainty Over Others' Mental Models

Up until this point the model assumed that players organize the set of alternatives using similar abstract mental models. However, there are many reasons why players may not have shared models or may be unsure of other players' understanding of the decision context. In this section I relax the assumption of mutual knowledge to allow some probability that a subset of players do not hold the same shared model. Thus, even though a unique coordination equilibrium may exist, the possibility of others "not being on the same page" may undermine the equilibrium. This logic also occurs in the well-known Stag Hunt game, where the presence of uncertainty about

others' understandings of the game may undermine the unique Pareto-optimal equilibrium. Factors such as cultural differences across players, high-risk situations, very large numbers of players, or a lack of institutional or social norms, may all contribute to a higher probability that miscoordination occurs (Jervis 1978).

Let $\mathcal{M}_i$ be the knowledge representation held by player i with knowledge-induced prescription k_i^*. The problem for coordination is that if one or more players has a different mental model then there is some probability that those players have a different knowledge-induced prescription and hence players will fail to coordinate. For simplicity, assume the uncertainty is constant across players and denote the probability of a shared knowledge structure as $\rho = prob(\mathcal{M}_j = \mathcal{M}_i)$ for all $j \neq i$. Then we are interested in the value of the expression $prob(k_i^* = k_j^*)$ for all $j \neq i$ given the probability ρ. Furthermore, we can explore the minimum-threshold values of ρ, denoted $\bar{\rho}$, such as when $prob(k_i^* = k_j^*) \geq .5$ for all $j \neq i$.

Let L_m denote the number of connected labeled graphs with m vertices and $\{L_m\}$ denote the set of such graphs. The following result summarizes the probability of coordination as a function of the number of players n, the number of strategies m, and the probability of a shared structure ρ.

Proposition 6 *Let $0 < \rho < 1$ be the probability that a player j's ($j \neq i$) knowledge representation $\mathcal{M}_j = \mathcal{M}_i$. The probability that all n players coordinate at a unique knowledge-induced equilibrium of $\mathcal{M}_i$ is*

$$\sum_{j=0}^{n-1} \binom{n-1}{j} \rho^{n-1-j}(1-\rho)^j \left(\frac{L_m - m}{L_m - 1} \cdot \frac{1}{m}\right)^j. \qquad (4)$$

Proof. The probability that all $n-1$ players have representation $\mathcal{M}_i$ (and hence the same knowledge-induced equilibrium) is ρ^{n-1}. The probability that $n-2$ players have representation $\mathcal{M}_i$ and exactly one player has a different knowledge representation is $\binom{n-1}{1}\rho^{n-2}(1-\rho)$. However, any player with a knowledge structure $\mathcal{M}_j \neq \mathcal{M}_i$ may still choose k_i^* if k_i^* is the knowledge-induced equilibrium of $\mathcal{M}_j$. By the symmetry of $\{L_m\}$, each vertex is a knowledge-induced equilibrium in $\frac{1}{m}$ of the graphs, hence the original knowledge-induced equilibrium k_i^* occurs with probability $\frac{1}{m}$. However, $\mathcal{M}_j$ is not drawn from the full set $\{L_m\}$ but from $\{L_m\} - \mathcal{M}_i$. The probability of k_i^* occurring in $\{L_m\} - \mathcal{M}_i$ is $\frac{1}{L_m - 1}\left(\frac{L_m}{m} - 1\right)$. (The probability of any of the $m-1$ alternatives not equal to k_i^* occurring in $\{L_m\} - \mathcal{M}_i$ is $\frac{1}{L_m - 1}\left(\frac{L_m}{m}\right)$ which gives $\frac{1}{L_m - 1}\left(\frac{L_m}{m} - 1\right) + (m - 1)\frac{1}{L_m - 1}\left(\frac{L_m}{m}\right) = 1$. Generalizing this logic into the weighted binomial sum for $2,3,\ldots,n-1$ players having different models yields

$$\rho^{n-1} + \binom{n-1}{1}\rho^{n-2}(1-\rho)\left[\frac{1}{L_m - 1}\left(\frac{L_m}{m} - 1\right)\right] + \binom{n-1}{2}\rho^{n-3}(1-\rho)^2\left[\frac{1}{L_m - 1}\left(\frac{L_m}{m} - 1\right)\right]^2 + \ldots,$$

which simplifies to Equation (4). ■

Table 1 shows how confident a player must be about others' mental models in order to achieve at least a 50 percent probability of coordination if he plays his own knowledge-structure prescription. For example, with five players and twenty strategies, a player needs to place an 83 percent chance on each other player sharing his own representation in order to guarantee a 50 percent probability of coordination at his knowledge structure prescription. Although the probability of coordination overall remains approximated by ρ^n for large numbers of alternatives, this analysis points out that some uncertainty does not undermine the idea of a knowledge-structure prescription—*provided the number of players is not too large.* The following proposition provides the information for the last column of Table 1.

Proposition 7 *As $m \to \infty$, the value of $\bar{\rho}$ such that $prob(k_i^* = k_j^*) \geq .5$ for all $j \neq i$ ap proaches $\bar{\rho} = (.5)^{\frac{1}{n-1}}$, where n is the number of players.*

TABLE 1 Confidence in Shared Models for prob(coordination) 50%. ($\bar{\rho}$ such that $prob(k_i^* = k_j^*) \geq .5$ for all $j \neq i$)

		Number of Alternatives (m)					
		3	4	5	10	20	∞
Number of Players (n)	3	.67	.62	.63	.67	.69	.71
	4	.77	.73	.74	.77	.78	.79
	5	.82	.79	.80	.82	.83	.84
	6	.85	.83	.84	.86	.86	.87
	7	.88	.86	.86	.88	.89	.89
	10	.92	.90	.91	.92	.92	.93
	20	.959	.953	.955	.960	.962	.964

Proof. Using the binomial expansion $\sum_{x=0}^{n-1}\binom{n-1}{x}a^x b^{n-1-x} = (a+b)^{n-1}$ with $a = (1-\overline{\rho})\left(\frac{L_m - m}{L_m - 1}\right)\left(\frac{1}{m}\right)$ and $b = \overline{\rho}$ from Equation (4) gives the inequality

$$\left((1-\overline{\rho})\left(\frac{L_m - m}{L_m - 1}\right)\left(\frac{1}{m}\right) + \overline{\rho}\right)^{n-1} \geq .5. \qquad (5)$$

As m increases, the value of L_m increases rapidly relative to m based on the series 4, 38, 728, 26704, ... (Sloane and Plouffe 1995, M3671), so the $\frac{L_m - m}{L_m - 1}$ term rapidly approaches one. In the limit as $m \to \infty$, Equation (5) simplifies to $\overline{\rho} \geq (.5)^{\frac{1}{n-1}}$. ■

Discussion

Nearly forty years ago Thomas Schelling proposed the idea of a focal point as an explanation of how players coordinate in an empirical setting. His insight was that a mental organization of the salient features of a decision context could potentially solve coordination problems even in the absence of communication or repeated play. This idea is so compelling that it is invoked to explain coordination outcomes in settings including collective action, third-party voting, campaign contributions, government regulations, international systems, and tariff policies (e.g., Chong 1991; Ainsworth and Sened 1993; Lohmann 1994; Spruyt 1994; Cox 1997; Scholz and Gray 1997; McGillvray 1997; O'Neill 1999). However, whereas a focal-point solution incorporates a payoff-independent labelling of the alternatives, a knowledge-induced equilibrium emphasizes the extent to which mental models are consistent with and constrain players' preferences. This shared restriction on the set of admissible preferences in turn facilitates coordination, despite conflicting ideal points among players.

The advantage of developing a formal model of the intersection of knowledge representations and choice is that it allows for a reexamination of the conditions that influence successful coordination. The model suggests some new implications for old variables and some new variables for future inquiry. Four variables immediately emerge from the model and results: (1) the number of choices in the action set, (2) the number of players, (3) the form of a knowledge structure, and (4) the extent to which mental models are shared. All these variables are empirically measurable.[16]

The number of choices and the number of players are frequently mentioned in association with coordination and bargaining. Since the combinations of possibilities explode with both these variables, it is typically inferred that both more choice and more players exacerbate a coordination problem. However, *if* players hold similar abstract mental models, then coordination over more choices is not necessarily more difficult, as seen in the Monte Carlo results. In fact, the coordination indeterminacy was significantly worse with only four choices than with six or ten or even twenty choices. If players put some nonzero probability on others holding a different mental model, then more choices still did not result in drastic changes to coordination prospects. For example, with five players, regardless of whether the coordination problem was over three or 100 choices, a probability of shared knowledge of .71 guaranteed a 50 percent chance of coordination if a player chose the knowledge-induced equilibrium of his own knowledge structure.

However, the number of players had a different effect. *If* players have shared mental models, then since a knowledge-induced equilibrium is defined from the knowledge structure, including more players makes little difference to the cognitive complexity of the problem since the maximum-likelihood winner is the same for all types of players. A puzzle in empirical political coordination is how large groups of players, as in collective action problems or third-party voting, manage to coordinate their actions given the exploding combinatorics on strategy vectors and beliefs. This model suggests that *if* there is some level at which players meta-organize their understandings of the choices (despite conflicting preferences over these choices), then coordination can still occur in large groups.

However, as the number of players increases presumably the empirical probability of shared mental models decreases, although some cultural anthropologists and evolutionary psychologists make arguments to the contrary (e.g., Barkow, Cosmines, and Tooby 1992; Romney et al. 1996). Regardless of the debates on culture or cognition, the formal results did show that larger numbers of players require a higher threshold for shared knowledge in order to achieve coordination. Furthermore, this threshold probability increases relatively rapidly. For example, although with only three players the

[16] The latter two variables are measurable using statistical techniques based on multidimensional scaling (e.g., Romney, Batchelder, and Weller 1987 in anthropology; Richards and Koenderink 1995 in cognitive science).

probability of shared knowledge must be only .71 or greater, for six players the threshold increased to .87, and by twenty players was .965.

The results also emphasize that the *form* of knowledge in a given empirical context is an important variable in coordination. Is knowledge represented as a tree or in rings or is there high or low symmetry in the organization? These qualitative attributes of the empirical context may be more important factors in coordination than simply the number of choices. Although the idea of structures of knowledge is not new in political science, the qualitative characteristics of the form of knowledge has not been considered as an important variable in predicting collective outcomes. In some cases, a knowledge structure suggests a unique prescription; in other cases it has little coordinating power. An example of empirical variations in the form of knowledge is evident in collective action problems of mass mobilization (e.g., Chong 1991; Lohmann 1994). My model formalizes how characteristics of a shared mental model can overcome the effects of large numbers of players. Most successful mass mobilizations have shared knowledge structures with strong uniqueness properties. Probably the best empirical example is the spontaneous gathering of East Germans on the Ringstrasse encircling Karl-Marx-Platz—a stark unique knowledge-induced equilibrium of probably every resident's mental map of central Leipzig (Lohmann 1994, 67–8).

Finally, although the model initially assumed a shared mental model among players, the extent to which a shared representation exists is an important variable for empirical applications of the model. For example, multiparty democracies involve coordination problems in that voters must coordinate on which of the smaller parties reaches the threshold for third-party representation (Cox 1997; Myerson and Weber 1993). If voters have shared cognitive organizations of these parties then the prospects for coordination among minority parties should be much greater than suggested by a traditional game-theoretic analysis. In contrast, where there is no shared cognitive organization of the parties, as in the case of emerging democracies with numerous newly formed political parties, coordination on third parties would be expected to be more difficult, leading to frequent changes in party representation and coalition structure.

As another example, there may be differences in the extent of structure between different subgroups of agents, as in Converse's (1964) assertion that the belief structure of elites is tighter than the belief structure of the masses. Groups with tightly structured shared mental models would be expected to coordinate more easily based on this additional information, whereas groups with loosely structured shared models would have more difficulty coordinating and would need to rely on other sources, such as institutions, to solve their coordination problems. Similarly, in conflict resolution bargaining (e.g., Schelling 1960; Legro 1995), the model suggests that coordination will be much more successful if (or when) a shared mental model emerges among the participants. Coordination can be facilitated by creating a shared understanding of the relationships among the feasible negotiation proposals. This implies that even nonenforcing third-party mediators (such as an individual diplomat, a nongovernmental organization, or an institution such as the United Nations) can potentially have great influence over the ability of participants to reach a coordinated agreement—if they can facilitate a convergence of the participants' representations of the bargaining context.

If the form and existence of shared knowledge matter in coordination, this points to the power of manipulating knowledge representations to influence coordination outcomes, as in Riker's (1983) concept of "heresthetic" (the art of structuring a choice context to one's benefit) or Myerson and Weber's (1993) "focal arbiter." Rather than sending a cheap talk signal of the form "I am going to choose A," one can expand the communication aspects to signals of the form "A is like B," where players communicate representations rather than intentions (Banks and Calvert 1992; Palfrey and Rosenthal 1991). Since a knowledge-induced equilibrium is a global property of players' structure of the set of alternatives, small changes in this structure can have a big effect on the attributes of the equilibria. One way knowledge structures can be influenced is by adding or subtracting new alternatives or by changing perceptions of how alternatives are related (e.g., Riker 1983; Sebenius 1983; Myerson and Weber 1993; Jones 1994; Bawn 1999). For example, let $\mathcal{M}$ be the graph with $E = (a_1a_2, a_3a_2, a_3a_4, a_4a_1)$. The addition of a new action to the choice set: a_5 with $a_5a_2 \in E$, transforms the game from one where the full set of outcomes are knowledge-induced equilibria to a game with a unique equilibrium at all players choose a_2. Arguing relationships among existing alternatives can also radically shift the coordination outcome. Let $\mathcal{M}$ be the graph with $E = (a_1a_2, a_3a_2, a_2a_4, a_4a_5, a_5a_6, a_6a_7)$. The addition of an edge linking a_7 with a_2 in a knowledge structure shifts the outcome from all players choosing a_4 in equilibrium to all players choosing a_2. Manipulation of the knowledge structure can occur in simple ways such as arguing relationships and categories (such as assertions that "proposal A is like proposal B so if you like A you should like B"). It can also occur in more complex ways such as the framing effects of priming, or invoking relevant comparison dimensions as

in issue-saliency tactics in elections (e.g., Jones 1994; Cox 1997, 255–61), or making analogical arguments (e.g., Khong 1992). These simple examples highlight the importance of communication—not only of preferences or intent—but of representations of an empirical context.

Conclusion

I have presented a formal model of how players' mental models of an empirical decision context intersect with strategy choice to influence the prospects for a coordination equilibrium. This approach emphasizes that cognitive elements, particularly the representation of an empirical context through mental models, are an important structural factor that mediates between the interactions of agents and between agents and their collective environments. The representation of knowledge used here—namely categories and relationships between categories—is probably the simplest possible representation. Much richer representations are possible, including analogies, cause-and-effect models, schemas, classifications of sets, logical systems, spatial representations, and so on. The model outlined here can be extended to take into account these more complex organizations of knowledge. Furthermore, a knowledge structure need not be modeled as static, but can be viewed as a dynamic structure that emerges through the interactions of agents (such as through deliberation, manipulation, or signaling (Richards 2000)). This would bring in communication and emergent structures, although the intent of this article is to demonstrate the effects of shared knowledge even in the absence of communication. The set of categories also need not be fixed in advance but can evolve as a representation is constructed.[17] Finally, this is a formal model where the empirical context matters.

It is worthwhile clarifying the relationship between the knowledge-induced equilibrium defined here and the related equilibrium concept of a structure-induced equilibrium defined for cooperative games (Shepsle 1979). A knowledge-induced equilibrium is based on general maximum-likelihood procedures and thus can be defined for both social choice (where the maximum-likelihood procedure becomes plurality rule as in Richards, McKay, and Richards [1998, 2000]) and for noncooperative games as shown here. In addition, a knowledge-induced equilibrium is based on the organization of preferences as mutually consistent with players' mental representations of the context, rather than on procedural rules and jurisdictions. But both a knowledge-induced equilibrium and a structure-induced equilibrium incorporate structure from the empirical context (whether it is an institutional or cognitive organization) to constrain and organize the set of players' preferences and induce equilibrium properties.

The idea of a knowledge-induced equilibrium reminds us that there are other sources of structure that induce stability in collective choice. Furthermore, these structures may have interesting relationships between them, such as the relationship between institutions and mental models, or mental models and cultural or social norms. However, the almost exclusive emphasis on institutional rules and procedures as the mechanism for facilitating collective agreements implies that without strong institutions the prospects for stable agreements are slight. This is not the case. Even in realms without institutional restrictions on preferences, such as in international politics or politics outside of parliaments or committees, preferences may be structured by shared cognitive interpretations of the empirical context which are sufficient to induce stable collective choices.

Appendix
Maximum Likelihood and Borda Winner

Lemma 8 *The alternative that is the maximum-likelihood winner of* Γ *is the action with the greatest pairwise wins minus losses, which is equivalent to the action that is the Borda winner.*

Lemma 8 is based on the results of Young (1986, 1988, 1995), who examines optimal aggregation rules as a problem of statistical inference using maximum-likelihood estimation. Let $A = \{a_1, \ldots, a_m\}$ be m distinct actions. Assume that the goal is to correctly identify the "best" action(s) after a series of independent pairwise comparisons. A series of pairwise comparisons on a set of m alternatives A is represented by an $m(m-1)$-dimensional vector $\mathbf{x} = (x_{jk})$, $1 \quad j \quad k \quad m$, consisting of nonnegative integer entries where x_{jk} is the number of comparisons in which a_j is "better than" a_k. If two actions are equally "best" in any single pairwise comparison, then it is assumed that each is selected with probability 1/2. It is assumed that pairwise trials are independent and that every action is involved in an equal number of

[17] Most decision theories must assume an *a priori* fixed set of alternatives (called the "small world assumption"), which is often a hindrance in applying formal models to dynamic empirical contexts.

comparisons c. The sampling distribution within the c comparisons corresponds to the distribution of combinations of the players' types given $\varnothing$.

Let $g(\mathbf{x}|a_k)$ be the probability of observing $\mathbf{x}$ given that a_k is the "best" action, where

$$g(\mathbf{x}|a_k) = p^{\sum_{j=k} x_{kj}} (1-p)^{\sum_{j\neq k} x_{jk}}. \quad (6)$$

Since for all $j \quad k$, $x_{jk} + x_{kj} = c$, the maximum-likelihood decision rule is (Young 1986, 116):

$$f(x) = \left\{ a_k \in A : \sum_{j\neq k} x_{kj} \geq \sum_{j\neq k} x_{lj}, \text{ for } 1 \leq l \leq m \right\}. \quad (7)$$

Equation 7 corresponds to choosing the action with the maximum number of wins minus losses over all pairwise comparisons, which corresponds to the action that is the Borda winner with probability weights $\varnothing$ (Young 1986, 116; Black 1958).

Proof of Theorem 5

Let v_1^* and v_3^* denote two knowledge-induced equilibria in a tree graph $\mathcal{M}$. Assume v_1^* and v_3^* are not adjacent so that there must be at least one vertex (or set of vertices), denoted v_2, with $e(v_2, v_1^*)$ and $e(v_2, v_3^*) \in \mathcal{M}$. Define a branch at a vertex u of a tree as the maximal subtree containing u as an endpoint. Let $\sum p(u)_{-x}$ denote the sum of the path lengths from root node u to all vertices descending from u excluding vertex x and its descendants. Let n_1 denote the number of vertices following from v_1^* as the root node excluding v_2 and its branches, n_2 be the number of vertices following from v_2 excluding v_1^* and its branches and v_3^* and its branches, and n_3 be the number of vertices following from v_3^* excluding v_2 and its branches. Since v_1^* and v_3^* are both knowledge-induced equilibria it must be that $\sum_{u\in\mathcal{M}} d(u, v_1^*) = \sum_{u\in\mathcal{M}} d(u, v_3^*)$, or that

$$\begin{aligned} &\sum p(v_1^*)_{-v_2} + 1 + 2 + \sum p(v_3^*)_{-v_2} + 2n_2 + \sum p(v_2)_{-v_1^*,-v_3^*} + n_3 \\ &= \sum p(v_3^*)_{-v_2} + 1 + 2 + \sum p(v_1^*)_{-v_2} + 2n_1 + \sum p(v_2)_{-v_1^*,-v_3^*} + n_3, \end{aligned} \quad (8)$$

which implies that $n_1 = n_2$. In order for v_2 not to be a knowledge-induced equilibrium, it must be that $\sum_{u\in\mathcal{M}} d(u, v_2)$ is not a minimum, or that

$$\begin{aligned} &\sum p(v_1^*)_{-v_2} + n_1 + 1 + \sum p(v_3^*)_{-v_2} + n_2 + 1 + \sum p(v_2)_{-v_1^*,-v_3^*} \\ &> \sum p(v_1^*)_{-v_2} + 1 + 2 + \sum p(v_3^*)_{-v_2} + 2n_2 + \sum p(v_2)_{-v_1^*,-v_3^*} + n_3, \end{aligned} \quad (9)$$

which results in the contradiction $n_3 < -1$. Hence v_1^* and v_3^* must be adjacent if they are knowledge-induced equilibria.

It remains to be shown that the set of adjacent equilibria cannot be greater than two. For v_1^*, v_2^*, and v_3^* to be knowledge-induced equilibria it must be that the sum of path lengths is minimal and equal:

$$\begin{aligned} &\sum p(v_1^*)_{-v_2} + 1 + n_2 + \sum p(v_2^*)_{-v_1^*-v_3^*} + 2 + 2n_3 + \sum p(v_3^*)_{-v_2^*} \\ &= 1 + n_1 + \sum p(v_1^*)_{-v_2^*} + \sum p(v_2^*)_{-v_1^*-v_3^*} + 1 + n_3 + \sum p(v_3^*)_{-v_2^*} \\ &= 2 + 2n_1 + \sum p(v_1^*)_{-v_2^*} + 1 + n_2 + \sum p(v_2^*)_{-v_1^*-v_3^*} + \sum p(v_3^*)_{-v_2^*}. \end{aligned} \quad (10)$$

In order for Equations (10) to be satisfied, it must be that $n_2 = -1$, which is a contradiction. ■

Coordination and Shared Mental Models

Diana Richards

In "Coordination and Shared Mental Models" (*American Journal of Political Science* 45(2): 259–276), a printer's error led to the omission of some inequality and "not equal to" symbols at several points in the text. The following are corrections.

The footnote on page 269 should read:

"Five hundred graphs were generated for cases with $m \leq 20$."

On page 270, every occurrence of "$j \quad i$" (lines 9, 11, and 13 in paragraph 2, the statements of Proposition 6 and 7, and the heading of Table 1) should read:

"$j \neq i$"

Also on page 270, the sixth line in the proof of Proposition 6 omits a "not equal to" symbol and should read:

"$\mathcal{M}_j \neq \mathcal{M}_i$"

Also on page 270, the first sentence in the heading of Table 1 should read:

"Confidence in Shared Models for prob(coordination) $\geq$ 50%."

On page 273, the eighth and ninth line after Lemma 8 should read:

"by an $m(m-1)$-dimensional vector $\mathbf{x} = (x_{jk})$, $1 \leq j \neq k \leq m, \ldots$."

Abstract

Many problems in computational number theory require the application of some sieve. Efficient implementation of these sieves on modern computers has extended our knowledge of these problems considerably. This is illustrated by three classical problems: the Goldbach conjecture, factoring large numbers, and computing the summatory function of the Möbius function.

Refined Restricted Permutations

By Aaron Robertson, Dan Saracino, and Doron Zeilberger

Written: March 4, 2002.

Appeared in Annals of Combinatorics v. 6 (2002), 427-444.

Derangements (and more generally the notion of "fixed points of a permutation") are concepts related to the cycle-structre, i.e. two-line notation, i.e. permutations qua *1-1 functions* from [1,n] to [1,n]. On the other hand, Pattern-avoidance (and Wilf- equivalence) are inherently "wordy", i.e. pertain to permutations qua *words*. Perhaps this is why no one noticed the amazing and easily-stated fact that the number of 132-avoiding derangements equals the number of 321-avoiding derangements, and even more amazingly, that the same is true if you replace "derangement" by "with i fixed points", for ANY i between 0 and n.

This astounding fact was first discovered emprically by Aaron Robertson who also has an even more amazing proposed proof for it, in terms of a beautiful bijection, that in particular gives the best proof todate of the classical Wilf-equivalence result of 321 and 132. But as hard as we tried, we were unable to prove that his bijection preserves the parameter "number of fixed points", even though it certainly does. This bijection that generalizes to other classes, will hopefully form the subject of forthcoming papers by Aaron, and I believe will revolutionize the theory of Wilf-equivalence. Meanwhile we found a more ``pedestrian" proof, that while somewhat boring to read, was lots of fun to discover, since without Shalosh it would not have been possible. Conversely, as hard as we tried, Shalosh and I were unable to make it completely computational (there must be a tip of a yet-to-be-discovered Ansatz here), and Aaron and Dan provided beautiful human insight to finish it up.

This article contains lots of other neat stuff discovered by Aaron and Dan, and its relation to the the very fine Fine sequence.

This paper is dedicated to the memroy of Rodica Simion (1955-2000), the great enumerator and wonderful human, who, we are sure, would have loved it.

.pdf version

IMPORTANT: This article is accompanied by the Maple package AARON , that emprically confirms many of the results, and that was very instrumental in finding the proofs, but that is not really needed for the proof itself (at least not for checking its formal correctness). It also requires: WILF. Notice that for AARON, the on-line help is ez(); not to interfere with the usual ezra(); that takes care of WILF.

Counting Pairs of Sequences by Size of Longest Common Subsequence

A polynomial time algorithm is presented for calculating the number of pairs of sequences of given lengths m and n (over a fixed alphabet) having a given length k for their longest common subsequence. The intended application is finding the most significant overlaps among DNA fragments as a first step in assembly.

Bob Robinson

Counting Feynman Diagrams

A Feynman diagram *D* of the type considered has a vertex set *U* of cardinality *2n* for some $n > 0$, along with *n* undirected *V*-lines forming a perfect matching on *U* and *2n* directed *G*-lines forming a permutation on *U*. Here *n* is called the *order* of *D*. One of the *G*-lines is designated as the *root* of *D*. If *D* is connected and cannot be disconnected by removing some two *G*-lines it is called *irreducible*. The number *C(n)* of nonisomorphic connected Feynman diagrams of order *n* has been known under various guises for at least 50 years. However the number *I(n)* of those which are irreducible appears to be new. The study of *C(n)* and *I(n)* is motivated by research which aims to combine Monte Carlo summation techniques with self-consistent high-order Feynman diagram expansions to computationally solve interacting fermion models in quantum physics.

A recently simplified approach to calculating the exact numbers *C(n)* and *I(n)* is presented. As time permits related results on the asymptotic behavior of *C(n)* and *I(n)* will be discussed, along with methods for generating canonical Feynman diagrams.

The main part of the talk will be an expanded version of a presentation at the ALICE '03 workshop; a detailed abstract is available in PostScript or PDF form.

Note: The research reported is being carried out for the NSF project "ITR/ACS: Stochastic summation of high-order Feynman graph expansions", led by Prof. H.-B. Schuttler of the UGA Physics Dept. (PI) with the speaker and others as co-PIs.

Bob Robinson

Generating Feynman Diagrams -- an Update

An overview and update on generating Feynman diagrams (FDs) is presented. There have been three previous seminars this academic year on generating and counting FDs; for the abstracts, see 26 Aug 2002, 11 Nov 2002, and 27 Jan 2003.

In this talk we present the basics of CAT generation algorithms for canonical FDs and for all labeled FDs, then discuss related open problems. Here CAT stands for "Constant Amortized Time".

Note: The research reported is being carried out for the NSF project "ITR/ACS: Stochastic summation of high-order Feynman graph expansions", led by Prof. H.-B. Schuttler of the UGA Physics Dept. (PI) with the speaker and others as co-PIs.

Rod Canfield

The Cauchy Integral Formula and Enumeration

Cauchy (1789-1857) is credited with discovering the Cauchy Integral Formula. When a function f(z) is defined by a power series

f(z) = \sum_{n=0}^{\infty} a_n z^n,

(z varies over complex numbers) the CIF allows you to express the coefficient a_n in terms of the numbers f(z) as z varies around a circle.

This is a useful technique in combinatorial enumeration, analytic number theory, mathematical physics, etc etc.

The two-part lectures will be intended to make the student, who is assumed to be familiar with complex numbers but NOT to have ever taken a course in complex analysis, an expert on the technique.

These lectures are tied in to the enumeration of bipartite graphs, some research done jointly with Brendan McKay. There was a lecture last Fall about a computer program for calculating said numbers. That lecture is independent of this one, but the overall goal is to work towards presenting the results of that research.

Embedding Problems for Paths and Cycles with Direction Constrained Edges*

We determine the reachability properties of the embeddings in 3D of a directed path, in the graph theoretic sense, whose edges have each been assigned a desired direction (East, West, North, South, Up, or Down) but no length. We ask which points of 3D can be reached by the terminus of an embedding of such a path, by choosing appropriate positive lengths for the edges, if the embedded path starts at the origin, does not intersect itself and respects the directions assigned to its edges. Similarly, we ask which graph theoretic cycles have physical realizations, without self-intersections, that respect the given direction constraints.

These problems arise in the context of extending planar graph embedding techniques and VLSI rectilinear layout techniques from 2D to 3D. We give combinatorial characterizations that yield linear time recognition and layout algorithms.

All are welcome. No special background is assumed.

How Feynman Diagrams Help to Resolve Mysteries in Physics

The interacting fermion problem is of fundamental importance in a wide range of physics research areas. It includes fields as diverse as electronic structure theory of solids, strongly correlated electron physics, quantum chemistry and the theory of nuclear matter. Especially the strange and still unrevealed nature of the high temperature superconductors has attracted a great deal of attention and remains still unsolved.

I will give an introduction into the problem and an overview about the ongoing project to combine a Monte Carlo summation techniques with a self-consistent high-order Feynman diagram expansions. I will present the basics steps necessary to carry out the task: the formulation of the model Hamiltonians and the use of Feynman diagrams to calculate basic physical quantities like the self-energy. Some interesting results for the Anderson impurity model will be presented.

Upper Tail Estimates and Their Applications

Given a random variable X, an important function is E[X], X's expected value. Typically, computations of E[X] are straightforward. In many applications, however, it's necessary to know a lot more about X than just E[X]. In particular, is X usually close to E[X]? If so, how close and how often? If X can be decomposed into the sum of smaller random variables, this is where the upper and lower tail probabilities are useful. Roughly, the lower tail is the probability that X falls below its expectation by a lot and the upper tail is the probability that X is way above its expectation In the case that X is the sum of independent indicator random variables, the Chernoff bound will give bounds for the upper and lower tail that are asymptotically equivalent. When X is the sum of small products of indicator random

variables, there is an analogue of the Chernoff bound for the lower tail, but no matching upper tail bound exists in general. Recently, interesting methods to deal with the upper tail have been developed and applied in Combinatorics and Computer Science. We'll survey some of these bounds, including Azuma's Inequality, Talagrand's Inequality, and Kim-Vu Concentration, as well as some purely combinatorial techniques, as time permits. Most of the background for this talk comes from the recent paper "The Infamous Upper Tail" by Svante Janson and Andrzej Rucinski.

Testing Homotopy for Paths in the Plane

We present an efficient algorithm to test if two given paths are homotopic; that is, whether they wind around obstacles in the plane in the same way. For paths specified by n line segments with obstacles described by n points, several standard ways achieve quadratic running time. For simple paths, our algorithm runs in $O(n\log{n})$ time, which we show is tight. For self-intersecting paths, the problem is related to Hopcroft's problem; our algorithm runs in $O(n^(2/3)\log{n})$ time.

Ununfoldable Polyhedra with Convex Faces

Unfolding a convex polyhedron into a simple planar polygon is a well-studied problem. We study the limits of unfoldability by studying nonconvex polyhedra with the same combinatorial structure as convex polyhedra. In particular, we give two examples of polyhedra, one with 24 convex faces and one with 36 triangular faces, that cannot be unfolded by cutting along edges. We further show that such a polyhedron can indeed be unfolded if cuts are allowed to cross faces. Finally, we prove that "open" polyhedra with triangular faces may not be unfoldable no matter how they are cut.

Towards a New Dimension for Process-Aware Information Systems

In the future, success or failure of an enterprise will more and more depend on its ability to flexibly and quickly react to changes at the market, the development, or the manufacturing side. This means that the flow of work within a department, within a company, or even across companies may have to be quickly adapted. To meet this challenge enterprises are developing a growing interest in supporting their business processes more effectively and in streamlining their computer applications such that they behave "process-oriented".

In principle, workflow (WF) technology offers a promising approach for this. It allows to define processes explicitly, to integrate application components, and to deliver a state-aware control service. However, current WF technology is jumping much too short. After being implemented, processes are rather inflexible and later changes in the process schema cannot be mapped to running instances. These and other weaknesses limit the applicability of WF technology significantly and will lead to big headaches for its users.

The target of the ADEPT project is to develop the fundamentals for a WF technology which makes process-aware applications easy to implement and which is much more flexible than today's systems. Very challenging in this context is to achieve this in an efficient manner and without violating consistency and robustness.

In the first part, Peter Dadam will describe the demands for adequate WF technology and illustrate the "technological vision" we are trying to make reality in our research. In the second part, Manfred Reichert will discuss the technological approaches taken in the ADEPT project in order to meet these goals. Among other things, he will present the developed framework for dynamic WF changes, which enables both, the quick and correct propagation of WF type changes to in-progress WF instances and the ad-hoc adaptation of single WF instances.

The presentation will be complemented by a live demonstration of the experimental ADEPT workflow engine.

Peter Dadam is full professor at the University of Ulm and director of the DBIS department. Before he was director of the department for Advanced Information Management (AIM) at the IBM Heidelberg Science Center where he managed the AIM-P project on advanced database technology. Current research areas include cooperative information systems, WF management, and database technology and its use in advanced application areas.

Manfred Reichert is assistant professor in the DBIS department at the University of Ulm. He finished his PhD thesis on flexible WF management in May 2000. Current research topics include enterprise-wide

and cross-organizational workflows, enterprise application integration and workflow, and different aspects related to WF technology.

Minimal Enclosings of Group Divisible Block Designs

The birth of combinatorial design theory can be traced back to Euler's discovery of the Latin Square over 200 years ago. Since that time, Balanced Incomplete Block Designs have become one of the most studied type of design in combinatorial design theory. This can be attributed to the variety of applications they have in the design of statistical experiments. This talk will review the concept of Balanced Incomplete Block Designs, and then introduce a generalization - Group Divisible Designs (where 'Group' refers to an element in a partition of objects). Necessary conditions for the existence of such designs and when such conditions are sufficient will be discussed. The existence problem of minimal enclosings of Group Divisible Designs will be introduced, as will necessary conditions for such enclosings. A few simple examples of minimal enclosings for small Group Divisible Designs will be shown. Generalizations of such enclosings and open problems will be discussed as time permits. No knowledge of design theory or combinatorics will be assumed. An elementary knowledge of some concepts from graph theory might be helpful.

Rod Canfield

Locally Restricted Compositions*

Compositions $n=a_1+a_2+\cdots$, $a_k>0$, have been studied classically. More recently, compositions with the local restriction $a_k\ne a_{k+1}$ (Carlitz compositions) have been studied by various authors. We consider the compositions with more general local-nonequality restrictions, including multiline compositions. We obtain recursions, bounds on growth rate, and other properties of a randomly selected restricted composition.

Parameter Estimation for Stochastic Grammar Modeling of RNA Pseudoknots*

Stochastic grammar models of RNA pseudoknots have been introduced to automate RNA pseudoknot prediction. However, the accurate estimation of the probability parameters of such grammar models from training sequences is difficult because of the inherent context-sensitivity in these grammars. In particular, existing algorithms for parameter estimation, such as Inside-outside, are applicable only to stochastic context-free grammar (SCFG) models for RNA stem-loop structures.

We introduce a new parameter estimation algorithm Upward-downward for the stochastic grammar model of RNA pseudoknots developed recently. The algorithm generalizes inside and outside probabilities for pseudoknot substructures by propagating probabilities of crossing double helices upward and downward in the derivation tree to accomplish the computation of inside and outside probabilities. The algorithm is a non-trivial extension of Inside-outside to RNA pseudonot models which was heretofore not available.

*This is joint research with Drs. Liming Cai and Russell Malmberg. The paper is HERE.

Congzhou He

Memory-Efficient Pseudoknot Prediction with Stochastic Grammar Modeling

The prediction of RNA pseudoknotted structure is computationally intractable due to the structural complexity of crossing nucleotide base pairs. Almost all existing prediction algorithms entail O(n^4)

memory space, making it unrealistic to predict pseudoknots for RNA molecules of even moderate length. We use techniques that reduce the resource requirements significantly to O(n^2) in memory space without substantial sacrifice in running time, and which avoid an exhaustive search for crossing helices in pseudoknots. Experiments conducted on baterial tmRNA demonstrate that the improved algorithm with O(n^2) space requirement achieves the same prediction accuracy as the optimal prediction algorithm with O(n^4) space requirement.

Junfeng Qu

Bellman-Ford Algorithm and Arbitrage Opportunity

The use of computers in the finance industry has been marked with controversy lately as programmed trading -- designed to take advantage of extremely small fluctuations in prices -- has been outlawed at many Wall Street firms. The ethics of computer programming is a fledgling field with many thorny issues. The presentation tries to use the Bellman-Ford algorithm to discover the arbitrage opportunity in currency exchange. A tentative solution is proposed with further suggestions given.

CATS

Conjunctive Selection Conditions in Main Memory

Kenneth A. Ross*
Columbia University
kar@cs.columbia.edu

ABSTRACT

We consider the fundamental operation of applying a conjunction of selection conditions to a set of records. With large main memories available cheaply, systems may choose to keep the data entirely in main memory, in order to improve query and/or update performance.

The design of a data-intensive algorithm in main memory needs to take into account the architectural characteristics of modern processors, just as a disk-based method needs to consider the physical characteristics of disk devices. An important architectural feature that influences the performance of main memory algorithms is the branch misprediction penalty. We demonstrate that branch misprediction has a substantial impact on the performance of an algorithm for applying selection conditions.

We describe a space of "query plans" that are logically equivalent, but differ in terms of performance due to variations in their branch prediction behavior. We propose a cost model that takes branch prediction into account, and develop a query optimization algorithm that chooses a plan with optimal estimated cost. We also develop an efficient heuristic optimization algorithm.

We provide experimental results for a case study based on an event notification system. Our results show the effectiveness of the proposed optimization techniques. Our results also demonstrate that significant improvements in performance can be obtained by applying a methodology that takes branch misprediction latency into account.

1. INTRODUCTION

Main memories are getting bigger and cheaper. It is now feasible for many applications to store the application data completely in a main memory database, in order to improve query and/or update performance.

Many traditional database algorithms need to be reconsidered for main memory databases. In this paper, we focus on one commonly-used database operation, namely applying a conjunction of selection conditions to a set of database records. One wishes to obtain those records satisfying the conjunction of conditions in as efficient a way as possible.

Our discussion will take the perspective that the application's data is stored in a main memory database. However, the problem we shall address is also relevant for information processing systems that are not considered "traditional" database systems. Examples include search engines, event notification systems, and network management systems. In each of these types of systems, one commonly poses queries involving the selection of records satisfying a conjunction of conditions.

In a disk-based database, it is usual to consider the performance parameters of the disk devices when designing database algorithms. For example, the high cost of random I/O compared with sequential I/O leads to algorithms that process the data in physical order. The relatively large size of a disk block leads to algorithms that try to cluster related data into disk-block sized units.

In a main-memory database we face similar design criteria, although the device characteristics are different. A feature with a significant impact on algorithm design is the delay induced when the CPU executes a conditional branch instruction and predicts the outcome incorrectly (i.e., the branch misprediction penalty). All else being equal, algorithms that have fewer branch mispredictions are likely to perform better than alternatives.

In this paper we consider how to design efficient algorithms for applying a conjunction of selection conditions given the characteristics of the CPU and memory hierarchy. We show that the branch misprediction penalty can have a significant impact on the performance of an algorithm.

We propose a class of algorithms that we consider as potential "plans" for combining selection conditions. To address the branch prediction issue, we develop a cost model that takes branch prediction into account. We then develop an exhaustive query optimization algorithm for choosing among

*This research was supported by NSF grants IIS-98-12014, IIS-01-20939, EIA-98-76739, and EIA-00-91533. Part of this work was performed while the author was visiting the INRIA Rocquencourt research institute.

such plans in a cost-based fashion, using dynamic programming. We also derive results that allow us to safely prune the search space of potential plans. We then develop a heuristic optimization method with lower complexity that performs well in practice.

We present a case study of the proposed methods in the context of an event-based notification system [16, 8]. Our experimental results show that significant performance improvements can be obtained. Our optimization algorithm and its cost model are validated against actual performance.

Past work has identified that branch misprediction has a significant impact on modern database systems [1]. To our knowledge, the present paper provides the first discussion of methods for avoiding branch misprediction penalties in database systems.

2. BACKGROUND

Modern CPUs have a pipelined architecture in which many instructions are active at the same time, in different phases of execution. Conditional branch instructions present a significant problem in this context, because the CPU does not know in advance which of the two possible outcomes will happen. Depending on the outcome, different instruction streams should be read into the pipeline.

CPUs try to *predict* the outcome of branches, and have special hardware for maintaining the branching history of many branch instructions. Such hardware allows for improvements of branch prediction accuracy, but branch misprediction rates may still be significant. Branches that are rarely taken, and branches that are almost always taken are generally well-predicted by the hardware. The "worst-case" branch behavior is one in which the branch is taken roughly half of the time, in a random (i.e., unpredictable) manner. In that kind of workload, branches will be mispredicted half of the time.

A mispredicted branch incurs a substantial delay. [1] reports that the branch misprediction penalty for a Pentium II processor is 17 cycles.

As a result, one might aim to design algorithms for "kernel" database operations that exhibit good branch-prediction accuracy on modern processors [10]. In fact, this is precisely our approach.

Future architectures, such as Intel's IA-64, support a technique called "predication" that converts control dependencies (i.e., conditional branches) into data dependencies. This technique allows the elimination of some branch instructions. However, it is not always beneficial to use it [7]; sometimes the original branching code is more efficient. Thus we expect branch misprediction penalties to continue to be a significant issue for the next generation of architectures.

There has been some past work on main memory database performance. Since pointer following is inexpensive in a main-memory database, it can pay to store attribute values as pointers to some external piece of allocated memory, often called a *domain* [17, 23]. Specialized algorithms for query processing in main-memory databases have been proposed in [17]. In [20], the authors suggested several ways to improve the cache reference locality of query processing operations such as joins and aggregations. [3] proposes improving cache behavior by storing tables vertically and by using a cache conscious join method. Cache-sensitive indexes for main memory databases are described in [18, 19].

It has been observed that specialized memory-resident techniques allow substantial performance gains over buffer-resident data in a disk-based system [9, 13, 14]. More recently, [2] describes ways to organize pages in a disk-based database system so that database operations give good CPU performance when the pages are memory resident in the database buffer.

3. COMBINING SELECTIONS

We define the *selectivity* of a condition applied to a table to be the proportion of records in the table satisfying the condition. This definition applies whether we're testing a single condition or a conjunction of conditions. Since one typically does not know the exact selectivities in advance, one performs query optimization using estimates of the selectivities. For simplicity of presentation we assume that the selectivities are independent, so that one can multiply estimates of the single-condition selectivities to get joint selectivity estimates. Non-independent selectivities can also be handled by our techniques; see Appendix B.

Suppose we have a large table stored as a collection of arrays, one array per column, as advocated in [3].[1] The column datatypes are assumed to have fixed length. (Variable length attribute types can use the array representation by introducing an extra level of indirection, storing pointers in the array.) Let's number the arrays `r1` through `rn`. We wish to evaluate a number of selection conditions on this table, and return pointers (or offsets) to the matching rows.

Suppose the conditions we want to evaluate are `f1` through `fk`. For simplicity of presentation, we'll assume that each `fi` operates on a single column which we'll assume is `ri`. (The methods developed in this paper are not dependent on the assumption that the functions test just a single argument, or that a column is used in a single function.) So, for example, if `f1` tests whether the first attribute is equal to 3, then both the equality test and the constant 3 are encapsulated within the definition of `f1`. We also assume that functions are well-defined in a self-contained way, in the sense that they always execute without error for any possible parameter value. For example, if `f2` dereferences a pointer that is not guaranteed to be non-null, then `f2` must also encapsulate a precondition testing whether the pointer is null. `f2` cannot rely on `f1` testing that pointer, say, because we intend to reorder the execution of the functions. Functions are discussed at more length in Appendix D.

3.1 Context

Our discussion assumes that the cost of processing the selections is a significant cost within the overall query, and

[1] If we have a single array of rows, as opposed to an array per column, the formulation of the problem is the same. The disadvantage of row-wise storage is that it has poor data reference locality for scans that consult just a few columns.

therefore worth optimizing. This assumption is certainly true when the selections constitute the entire query. When the selections form the initial step of a more complex query, processing the selections may still be a significant (or even dominant) cost since a selective selection operation will need to consult many more records than operations applied after the selection.

We describe three typical contexts in which a set of selection conditions is applied. In the first context, we simply apply the conditions to each record in the underlying table. This approach would be used if indexes are not helpful, either because we lack the required index, or because the condition selects such a large proportion of the records that it is not worth the overhead of using the index.

In the second context, we identify one (or more) of the selection conditions as corresponding to an indexed attribute; using the index can speed up processing. In the third context, a selection condition is applied to a "dimension" table referenced by a foreign key in the main "fact" table. Preprocessing the dimension table can improve efficiency.

As we shall see, each of the contexts has a common structure: There is a loop that iterates over all (partially matching) records, and inside the loop is code to (a) test the records for the remaining conditions, (b) AND the results together, and (c) add qualifying record-ids to the answer list.

The straightforward way to code the selection operation applied to all records (context 1) would be the following. The result is returned in an array called `answer`. In each algorithm below, we assume that the variable `j` has been initialized to zero.

```
/* Basic Algorithm Structure */
for(i=0;i<number_of_records;i++) {
  if(f1(r1[i]) AND ... AND fk(rk[i]))
    {answer[j++] = i;}
  }
```

Alternatively, suppose that `f1` was a condition that could be evaluated efficiently using an index on `r1` (context 2). For example, `f1` might be an equality test, and using an index on `r1` we may be able to obtain an array `matches` of offsets `i` of records satisfying `f1(r1[i])`. Then the remaining conditions can be tested using the following code.

```
/* Index Algorithm Structure */
for(m=0;m<number_of_matches;m++) {
  i=matches[m];
  if(f2(r2[i]) AND ... AND fk(rk[i]))
    {answer[j++] = i;}
  }
```

Indexes may be combined by intersecting `match` arrays.

It is common for queries over a fact table in a data warehouse to place selections on dimension tables (context 3). Suppose `r1` was a foreign key (i.e., offset) to a dimension table, and that `f1` was a selection condition on some column `c` of the dimension table. Then `f1(r1[i])` could be written as `g1(c[r1[i]])`. Since dimension tables are generally small, it may pay to evaluate `g1` on all rows of `c` in advance, and store the result in a temporary array `t`. (This saves repetitive execution of `g1` on duplicate values.) Thus we could modify the basic algorithm structure to perform the selection as

```
/* Preprocess Dimension Table */
for(i=0;i<records_in_c;i++){t[i]=g1(c[i]);}
for(i=0;i<number_of_records;i++) {
  if(t[r1[i]] AND ... AND fk(rk[i]))
    {answer[j++] = i;}
  }
```

3.2 Implementing the Loop

In the following discussion we'll use the code from the first context, i.e., applying the selection conditions to all records one by one. However, similar principles apply to the other contexts. Translated into `C`, the code for the inner loop might be:

```
/* Algorithm Branching-And */
for(i=0;i<number_of_records;i++) {
  if(f1(r1[i]) && ... && fk(rk[i]))
    {answer[j++] = i;}
  }
```

The important point is the use of the `C` idiom "`&&`" in place of the generic "`AND`". (See Appendix A for a discussion of how `&&` is typically compiled into assembly language containing conditional branch instructions.) This implementation saves work when `f1` is very selective. When `f1(r1[i])` is zero, no further work (using `f2` through `fk`) is done for record `i`. However, the potential problem with this implementation is that its assembly language equivalent has `k` conditional branches. If the initial functions `fj` are not very selective, then the system may execute many branches. The closer each selectivity is to 0.5, the higher the probability that the corresponding branch will be mispredicted, yielding a significant branch misprediction penalty. (Recall the discussion of branch prediction effectiveness in Section 2.) An alternative implementation uses logical-and (`&`) in place of `&&`:

```
/* Algorithm Logical-And */
for(i=0;i<number_of_records;i++) {
  if(f1(r1[i]) & ... & fk(rk[i]))
    {answer[j++] = i;}
  }
```

Because the code fragment above uses logical "`&`" rather than a branching "`&&`", there is only one conditional branch in the corresponding assembly code instead of `k`. (Again, see Appendix A for a discussion of how `&` is compiled into assembly language.) We may perform relatively poorly when `f1` is selective, because we always do the work of `f1` through `fk`. On the other hand, there is only one branch, and so we expect the branch misprediction penalty to be smaller.

The branch misprediction penalty for that one branch may still be significant when the combined selectivity is close to

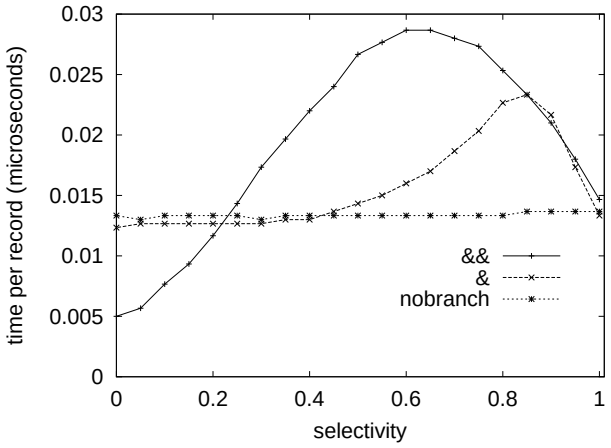

Figure 1: Three implementations: Pentium.

0.5. The following loop implementation has *no* branches within the loop.

```
/* Algorithm No-Branch */
for(i=0;i<number_of_records;i++) {
  answer[j] = i;
  j += (f1(r1[i]) & ... & fk(rk[i]));
  }
```

Note that we would not expect an optimizing compiler to be able to transform one of these plans into another. Most importantly, such transformations are not valid in the general case. For example, in the condition `(A && B)`, `A` may check that a pointer is not null, while `B` dereferences that pointer. Executing `(A && B)` makes sense, while executing `(A & B)` would cause an error if the pointer was null. While our assumption about functions does make `(A & B)` valid in the case where `A` and `B` represent functions `fi` and `fj`, it is not possible to communicate such information to modern compilers. Further, even if one was to extend the compiler with such a mechanism, the decision on whether to rewrite the code depends on database-level metadata, such as condition selectivities, that are not generally available to the compiler.

To see the difference between these three methods, we implemented them in `C` and ran them on a 750Mhz Pentium III under Linux, and a 300Mhz UltraSparc IIi under Solaris. In the following experiment, we used $\mathtt{k} = 4$ and let all of the `rj` arrays be offsets into an array `t` of `char`s of size 5000. Elements of `t` are either 1 or 0, simulating the preprocessing of conditions on dimension tables. The `fj` functions are then lookups in `t`. We ran several thousand scans over four arrays of size 3000, using the same `t` array. That way, both `t` and the arrays are in the L1 cache and the experiments will not reflect delays due to cache misses. (We briefly address caching issues Appendix D.) The code was compiled with `gcc` under maximum optimization, with several `register` hints present in the code.

Figure 1 shows the Pentium results. (See Appendix C for the Sun results.) While both architectures show some dependence on the selectivity, the Pentium results are more sensitive to the selectivity because the branch misprediction penalty is higher on that architecture [25]. The time per record is shown in microseconds on the vertical axis, measured against the probability that a test succeeds. The probability is controlled by setting an appropriate threshold for an element of the `t` array to be randomly set to 1. All functions in this graph have the same probability.

Our preliminary analysis of the three implementations is borne out by this graph. For low selectivities, the branching-and implementation does best by avoiding work, and the one branch that is frequently taken can be well-predicted by the machine. For intermediate selectivities, the logical-and method does best. However, when the combined selectivity gets close to 0.5, the performance worsens. The no-branch algorithm is best for nonselective conditions; it does more "work" but does not suffer from branch misprediction.

Each of the three implementations is best in some range, and the performance differences are significant. On other ranges, each implementation is about twice as bad as optimal. Thus we will need to consider in more depth how to choose the "right" implementation for a given set of query parameters.

Looking at the performance numbers, one might wonder why we care about per-record processing times that are fractions of a microsecond. The reason we care is that this cost is multiplied by the number of records, which may be in the tens or hundreds of millions. When we don't have an index, we have no choice but to perform a full scan of the whole table. Even when we're scanning fewer records per query, the overall performance in queries-per-second is directly impacted by these performance numbers. In a dynamic query environment, for example, we might be aiming for video-rate screen refresh, and thus require the completion of 30 queries per second for each user. See Section 5 for another example.

From now on, when we show an implementation, we will omit the `for` loop, just showing the code inside the loop.

4. OPTIMIZING INNER LOOP BRANCHES

Using standard database terminology, we will refer to a particular implementation of a query as a *plan*. We now formulate our optimization question:

> Given a number `k`, functions `f1` through `fk`, and a selectivity estimate p_m ($m = 1, \ldots, \mathtt{k}$) for each `fm`, find the plan that minimizes the expected computation time.

So far we have seen three ways to write the inner loop. Each such plan has different performance characteristics. There are, in fact, many additional plans that can be formed by combining the three approaches. An example that combines all three is the following:

```
/* A Mixed Algorithm (loop code omitted) */
  if((f1(r1[i]) & f2(r2[i])) && f3(r3[i]))
    { answer[j] = i;
      j += (f4(r4[i]) & ... & fk(rk[i]));
    }
```

Significantly, several of these combination plans turn out to be superior to the three basic methods shown in Figure 1 over some selectivity ranges.

We will focus on finding a plan, consisting of some combination of the three methods presented above, giving the best expected time. We remark that there are other methods besides the three we have chosen for evaluating the inner loop. For example, one could add the function values rather than ANDing them, and compare with `k` at the end. (This alternative method might be useful in a hypothetical architecture in which an addition operation was faster than a logical AND.) Nevertheless, we expect that on realistic architectures, the three basic methods are among the most efficient.

4.1 A Normal Form for Combined Plans

For now, let us just consider plans involving a combination of the "branching-and" and the "logical-and" algorithms. We formulate how these two algorithms can be mixed, and consider when certain combinations are never optimal. Based on this notion, we derive a normal form for potentially optimal plans, and enumerate them.

A first glance at the two algorithms might suggest that all we need to do is consider all expressions within the `if` condition that can be formed out of the two kinds of "and" operation. However, this is clearly too many because `&` is commutative,[2] and both `&` and `&&` are associative. Additionally, if we are only interested in finding at least one optimal plan, we need only consider expressions in which all "outer" conjunctions are via `&&` and the conjuncts are terms involving only `&`.

To justify this assertion, consider the expression `E` given by `E0 && (E1 & (E2 && E3))` for arbitrary expressions `E0`, `E1`, `E2` and `E3`. (We allow `E0` to be empty, in which case there is no outer `&&`.) Consider the alternative expression `E'` given by `E0 && E2 && (E1 & E3)`. We claim `E'` is always more efficient than `E` on a non-parallel machine. In both cases the expression `E0` is evaluated. If `E0` is false, the performance is equivalent. If `E0` is true, then `E2` is evaluated in both `E` and `E'`. If `E2` is true, then both plans are again equivalent in terms of performance, since both `E1` and `E3` will be evaluated, and the same number of operations will be performed. However, if `E2` is false, then `E'` is superior to `E` because (a) it does not evaluate `E1` and (b) it avoids one `&` operation. By repeatedly applying the transformation from `E` to `E'` whenever we have a subexpression matching `E`, we essentially "pull up" all instances of `&&` to the top level. Each such transformation does not harm the performance, and in many cases improves it.

[2]We mean commutative in terms of performance rather than in terms of logic. Both arguments of `&` are evaluated and ANDed together; the order of evaluation does not affect the overall performance. Similarly, when we talk about associativity, we mean in terms of performance.

The order of the inner conjunctions (via `&`) does not matter, due to commutativity, and the parenthesization of the outer conjunctions (via `&&`) does not matter, due to associativity. We thus consider the inner conjuncts as sets of basic expressions, and the outer conjunction as being parenthesized from left to right. As outlined above, there must be an optimal plan in this normal form.

DEFINITION 4.1. *A single-function condition is called a* basic term. *A conjunction via* `&` *of basic terms is called an* `&`-term. *A conjunction via* `&&` *of* `&`*-terms is called an* expression. □

Let $t_{m,n}$ denote the number of normal-form plans over n basic terms, with exactly m occurrences of `&&`. Then $t_{0,n} = 1$ for all n. For the inductive case, consider prepending (via `&&`) an additional `&`-term to an expression with m occurrences of `&&`. Then

$$t_{m+1,n} = \sum_{i=1}^{n-1} \binom{n}{i} t_{m,n-i}.$$

We are actually interested in a_n, the number of plans, given by $a_n = \Sigma_{k=0}^{n} t_{k,n}$. Then $a_0 = 1$ and for $n > 1$ one can rearrange the above recurrence to get:

$$a_n = \sum_{j=1}^{n} \binom{n}{j} a_{n-j}.$$

This recurrence has been well-studied, as early as 1859 [4]; see [21] for further references. One representation of the solution [24] is that a_n is the closest integer to $n!/(2\ln^{n+1}(2))$.

Algorithm No-Branch can be thought of as a potential optimization to remove the final `if` test of a combined method. There is thus just one way to apply the optimization: to replace

```
if(E1 && ... && Ek)
  {answer[j++] = i;}
```

with

```
if(E1 && ... && Ek-1)
  { answer[j] = i; j += Ek;}
```

where the `Ei` terms are `&`-terms. Thus we should consider plans both with and without this optimization; the total number of potentially optimal plans is now $2a_n$.

4.2 Cost Functions

To compare the cost of the various plans, we need a cost model. The basic parameters of the model are: r, the cost of accessing an array element `rj[i]` in order to perform operations on it; t, the cost of performing an `if` test; l, the cost of performing a logical "and"; m, the cost of a branch misprediction; p_i, the selectivity of basic term i equal to the probability that basic term number i is 1; a, the cost of writing an answer to the answer array and incrementing the

answer array counter; f_i, the cost of applying function `fi` to its argument.

In our model, we will assume that the processor is perfect in its branch prediction, i.e., that it predicts the branch to the next iteration will be taken when the selectivity $p \leq 0.5$, and will not be taken when $p > 0.5$.

Given a plan, we add up the expected cost given the selectivities and the structure of the algorithm. We count just the cost of the code inside the loop, and not the loop iteration cost itself (since that's the same across all methods). We emphasize that in practice, one must model the costs for the assembly-language instructions generated by the compiler, rather than directly modeling the cost of the `C` code (see Appendix A).

EXAMPLE 4.1. *Consider Algorithm No-Branch on k basic terms. The total cost for each iteration is* $kr + (k-1)l + f_1 + \cdots + f_k + a$. □

EXAMPLE 4.2. *Consider Algorithm Logical-And on k basic terms, with selectivities* $p_1, \ldots, p_k$. *The total cost for each iteration is* $kr+(k-1)l+f_1+\cdots+f_k+t+mq+p_1 \cdots p_k a$, *where* $q = p_1 \cdots p_k$ *if* $p_1 \cdots p_k \leq 0.5$ *and* $q = 1 - p_1 \cdots p_k$ *otherwise. The q term describes the branch prediction behavior: we assume the system predicts the branch to the next iteration will be taken exactly when* $p_1 \cdots p_k \leq 0.5$. □

EXAMPLE 4.3. *Consider Algorithm Branching-And on k basic terms, with selectivities* $p_1, \ldots, p_k$ *(in the order listed in the* `if` *condition). The cost formula is the solution for* c_1 *of the recurrence*

$$c_n = r + t + f_n + mq_n + p_n c_{n+1} \qquad (1 \leq n \leq k)$$

where $q_n = p_n$ *if* $p_n \leq 0.5$ *and* $q_n = 1 - p_n$ *otherwise, and* $c_{k+1} = a$. *Again, the* q_n *terms describe the branch prediction behavior; in this algorithm we can execute as many as k conditional branches.* □

While this model captures the important aspects of the problem that are common across most modern architectures, it is not an exact cost calculation. Several architecture-dependent features make it approximate, including: out-of-order execution of instructions, overlapping memory access and computation, imperfect branch prediction based on just the most recent branches, and the degree of instruction-level parallelism present.

DEFINITION 4.2. *Let* `E` *be an* `&`*-term. The* fixed cost *of* `E`, *written fcost*(`E`), *to be the part of the cost of* `E` *that does not vary with the selectivity of* `E`. *In particular, if* `E` *contains k basic terms using* `f1` *through* `fk`, *then fcost*(`E`) $= kr + (k-1)l + f_1 + \cdots + f_k + t$. □

We can combine the observations of Examples 4.2 and 4.3 to derive a general recurrence for mixed plans: Consider the plan P_1 given by

```
if (E && E1) {answer[j++] = i;}
```

where `E` is an `&`-term and `E1` is a nonempty expression. Then the cost of this plan is

$$fcost(\texttt{E}) + mq + pC \tag{1}$$

where p is the overall combined selectivity of `E`, $q = \min(p, 1-p)$, and C is the cost of the plan P_2:

```
if (E1) {answer[j++] = i;}
```

In particular, for P_1 to be an optimal plan, P_2 must also be an optimal plan (for fewer terms). We use this observation as the basis for developing a dynamic programming solution to our problem in Section 4.4. First, though, we investigate ways to limit the plans we consider by eliminating term orders that cannot be optimal.

4.3 Term Order in Optimal Plans

Hellerstein et al. consider *expensive predicates*, i.e., where the computation needed for evaluating whether the predicate is true or false dominates the overall cost [12]. In that context, it is shown that predicates should be ranked in ascending order according to the metric $\frac{selectivity-1}{cost\text{-}per\text{-}tuple}$. Our context differs in that our predicates are often *cheap*, meaning that other costs such as the branch misprediction penalty cannot be ignored. Further, there could be a *higher* misprediction penalty for a *lower* selectivity, meaning that this ranking would not be correct when the penalty is sufficiently high. Nevertheless, our derivation of term orders below bears some similarity to this rank ordering approach.

LEMMA 4.1. *Consider plans of the form*

```
if (E1 && E2 && E) {answer[j++] = i;}
```

where `E1` *and* `E2` *are nonempty* `&`*-terms, and* `E` *is an arbitrary (possibly empty) expression. Let* p_1 *and* p_2 *be the selectivities for* `E1` *and* `E2` *respectively. Such plans cannot be optimal if* $p_2 \leq p_1$ *and* $\frac{p_2-1}{fcost(\texttt{E2})} < \frac{p_1-1}{fcost(\texttt{E1})}$. □

A corollary of this lemma is that whenever two consecutive `&`-terms appear anywhere as conjuncts of `&&` (i.e., not just leftmost) in an optimal plan, then the one with lower selectivity must appear first if it has the same *fcost*.

Note that Lemma 4.1 says nothing about the case where there is an intervening expression between the two `&`-terms. An analogous statement to Lemma 4.1 when there are intervening expressions between `E1` and `E2` fails for two reasons. First, when $p_1 > 1/2$ it is always possible to find a sufficiently large branch misprediction penalty and a value for p_2 less than p_1 such that switching the two basic terms leads to an *inferior* plan. Second, even when $p_1 \leq 1/2$, the condition $\frac{p_2-1}{fcost(\texttt{E2})} < \frac{p_1-1}{fcost(\texttt{E1})}$ is not strong enough to guarantee that switching `E1` and `E2` is a win. Nevertheless, when there are intervening terms we can state the following weaker lemma.

LEMMA 4.2. *Consider plans of the form*

```
if (E1 && X1 && E2 && X2)
  {answer[j++] = i;}
```

where `X1` *and* `X2` *are arbitrary (possibly empty) expressions,* `E1` *and* `E2` *are nonempty* `&`*-terms with respective selectivities* p_1 *and* p_2*, and* $p_1 \leq 1/2$*. Such plans cannot be optimal if* $p_2 < p_1$ *and* $fcost(\texttt{E2}) < fcost(\texttt{E1})$*.* □

A corollary of Lemma 4.2 is that when all selectivities are at most 1/2, a relatively common case, we can order `&`-terms `E` with selectivity p by the pair $(fcost(\texttt{E}), p)$. In our case $(x, y) < (x', y')$ if $x < x'$ and $y < y'$. This ordering on `&`-terms is partial, since it is possible to have incomparable pairs. The partial order constrains the order of `&`-terms in optimal plans.

DEFINITION 4.3. *We call the pair* $(\frac{p-1}{fcost(\texttt{E})}, p)$ *the* c-metric *of* `&`*-term* `E` *having combined selectivity* p*. We call the pair* $(fcost(\texttt{E}), p)$ *the* d-metric *of* `&`*-term* `E` *having combined selectivity* p*.* □

Note that if `E1` is less than `E2` according to the d-metric, then `E1` is also less than `E2` according to the c-metric, but not vice versa. We use Lemmas 4.1 and 4.2 in the dynamic programming algorithm below.

4.4 Finding Optimal Plans

When the number of basic terms is small, we could simply enumerate all normal form plans and calculate the cost, choosing the plan with the smallest cost. However, the number of plans grows factorially in the number of basic terms (Section 4.1), and so alternative methods are necessary in general.

We propose a dynamic programming solution to the problem that is outlined below.

ALGORITHM 4.1. **Optimal-Plan** *Let* S *denote the set of basic terms, and let* k *be the cardinality of* S*. Create an array* $A[]$ *of size* 2^k *indexed by the subsets of* S*. The array elements are records containing: The number* n *of basic terms in the corresponding subset; the product* p *of the selectivities of all terms in the subset; a bit* b *determining whether the no-branch optimization was used to get the best cost, initialized to 0; the current best cost* c *for the subset; the left child* L *and right child* R *of the subplans giving the best cost.* L *and* R *range over indexes for* $A[]$*, and are initialized to* $\emptyset$*.*

In the loops over subsets of S*, we iterate in an order consistent with the partial order of subsets of* S*. In other words, if* $s_1 \subset s_2$*, then* s_1 *comes before* s_2 *in the loop. We call such an order an "increasing" order below. Note that a standard encoding of subsets as bitmaps yields an increasing order if we simply increment the bitmap on each iteration.*

1. */* Consider all plans with no* `&&`*s */*
   Generate all $2^k - 1$ *plans using only* `&`*-terms, one plan for each nonempty subset* s *of* S*. Store the computed cost (Example 4.2) in* $A[s].c$*. If the cost for the No-Branch algorithm is smaller, replace* $A[s].c$ *by that cost (Example 4.1) and set* $A[s].b = 1$*.*

2. *For each nonempty* $s \subset S$ *(in increasing order)*
   / s is the right child of an* `&&` *in a plan */*
   For each nonempty $s' \subset S$ *(in increasing order) such that* $s \cap s' = \emptyset$ */* s' is the left child */*
   if (the c-metric of s' *is dominated by the c-metric of the leftmost* `&`*-term in* s*) then*
   {/ do nothing; suboptimal by Lemma 4.1 */}*
   else if ($A[s'].p \leq 1/2$ *and the d-metric of* s' *is dominated by the d-metric of some other* `&`*-term in* s*) then*
   {/ do nothing; suboptimal by Lemma 4.2 */}*
   else {
   Calculate the cost c *for the combined plan (*s' `&&` s*) using Equation 1. If* $c < A[s' \cup s].c$ *then:*

   (a) *Replace* $A[s' \cup s].c$ *with* c*.*
   (b) *Replace* $A[s' \cup s].L$ *with* s'*.*
   (c) *Replace* $A[s' \cup s].R$ *with* s*. }*

At the end of the algorithm, $A[S].c$ *contains the optimal cost, and its corresponding plan can be recursively derived by combining the* `&`*-conjunction* $A[S].L$ *to the plan for* $A[S].R$ *via* `&&`*.* □

Because the loops over the subsets of S are performed in increasing order, any newly-generated partial plan will be considered as part of larger plans later on, within the same loop. One never has to revisit plans that have already been considered.

The utility of the metric tests is that we avoid generating a large number of intermediate-quality plans that improve on the currently computed best cost, without being optimal. In practice, we need to verify that the reduction of the search space afforded by these tests outweighs the costs of the tests themselves.

The complexity of this algorithm is $O(4^k)$ which, while exponential, is asymptotically much better than generating and testing all normal-form plans (Section 4.1). Note that the algorithm simultaneously solves the optimization problem for all subsets of S too, so that one run of the algorithm can cover many potential loop structures.

Since we are typically interested in small values of k, the exponential complexity is not a barrier to its use in practice. We implemented the optimization algorithm in `C++` and ran it on both the Pentium III and the UltraSparc. The optimization time itself was always less than 0.01 seconds when $k \leq 9$, for various probability values. We investigate how well the output of the optimization algorithm matched actual performance time in Section 5.1.

4.5 A Heuristic Optimization Algorithm

While the optimization algorithm of the previous section is guaranteed to find the optimal solution, it still has exponential complexity. Thus, if we were to be presented with an optimization problem having a sufficiently large number of conditions, it would not be practical. Additionally, when the number of records to be processed is only moderate, we would want to spend just a small amount of time on optimization; the method of the previous section may be too expensive compared with the expected gains in evaluation time.

To address this problem, we present a heuristic method that takes linear space and has complexity $O(k \log k)$ in the average case, and $O(k^2)$ in the worst case. While the heuristic method is not guaranteed to find the optimal solution, we will demonstrate experimentally that it finds good solutions.

We begin by ordering the terms of the conjunction in ascending order according to the metric $\frac{selectivity-1}{cost\text{-}per\text{-}tuple}$. Our intuition is that, as for the expensive predicate case, ordering predicates in this way will be generally effective. However, this is just the start of the process: we still need to decide how to evaluate the conjunction using the three kinds of plans described above.

We treat the conjunction of k conditions as if it were to be evaluated using a Logical-And plan. We then move from left to right within the plan, evaluating the cost of the plan formed by replacing an `&` by an `&&`. We keep moving from left to right as long as the measured cost decreases. As soon as the measured cost increases, or we reach the end of the list, we terminate the left-to-right traversal. If we didn't reach the end of the list, we then spawn two recursive suboptimization processes, one for the left half of the expression, and one for the right. As a final tweak (not within the recursion), we replace the rightmost Logical-And subplan by a No-Branch subplan if the latter has lower cost.

For example, consider the basic terms ordered according to the metric above as $E_1, E_2, \ldots, E_k$. We evaluate the cost of $E_1\&\&(E_2\& \ldots \&E_k)$, then $(E_1\&E_2)\&\&(E_3\& \ldots \&E_k)$, and so on, until the plan $(E_1\& \ldots \&E_i)\&\&(E_{i+1}\& \ldots \&E_k)$ is less costly than $(E_1\& \ldots \&E_{i+1})\&\&(E_{i+2}\& \ldots \&E_k)$. We then recursively apply the heuristic to the subexpressions $(E_1\& \ldots \&E_i)$ and $(E_{i+1}\& \ldots \&E_k)$ to get plans P_1 and P_2 respectively. The final returned plan is $P_1\&\&P_2$, with a possible modification of P_2 to use a No-Branch plan for its rightmost term.

The analysis of this algorithm is very similar to the analysis of quicksort. It takes linear space, worst-case quadratic time, and $k \log k$ time on average assuming randomly distributed termination points in the left-to-right traversal.

The intuition behind the method is that once we have decomposed a plan P into one of the form $P_1\&\&P_2$, then P_1 and P_2 can be optimized independently; they do not depend on each other. The placement of the top-level && within P is done heuristically, assuming that the plan for the right-hand-side is the Logical-And plan. At the cost of adding complexity, one could consider alternative plans for the right-hand-side in order to determine a better partitioning point.

We shall study the quality of plans generated by the heuristic optimization method experimentally in Section 5.1. In terms of optimization time, our implementation on both the Pentium III and the UltraSparc takes less than 0.01 seconds consistently for $k \leq 60$. For $k = 4$ the optimization time was consistently less than 16 microseconds.

5. CASE STUDY

To demonstrate that our solution constitutes a feasible solution to realistic classes of problems, we describe a case study in which we apply these techniques in the context of a prototype event-based notification system called "Le Subscribe" [16, 8].

Le Subscribe aims to store millions of subscriptions, and to match hundreds of events per second against these subscriptions. Each subscription specifies a conjunction of simple conditions to apply to events, such as numeric equalities and inequalities. Where possible, subscriptions are partitioned into clusters based on equality conditions in the subscriptions. When an event arrives, it needs to be matched against clusters that agree with the event on the value of the partitioning attribute(s), as well as against subscriptions having no equality conditions.

Subscriptions are grouped based on the number of conditions. So, subscriptions with two conditions are grouped together for example. A group with `k` conditions is stored as a collection of `k` one-dimensional arrays `r1[i]`, ..., `rk[i]`. The `i`th entry in each array is a condition from the `i`th subscription.

Conditions are simply pointers to memory locations containing boolean values. Whenever an event arrives, the global set of boolean values is updated to reflect the characteristics of the event. That way, repetitive checking of conditions by thousands of subscriptions is avoided. The overall performance of the matching system is measured by how many events per second can be matched for a given number of subscriptions.

Matching against a group of subscriptions takes place using a sequential scan of the corresponding arrays. For a discussion of how Le Subscribe employs prefetching, see [8]. Subscriptions do not change rapidly. Thus one can obtain good estimates of selectivity for each `ri` by either estimating the distribution of events, or by keeping track of historical selectivities.

It is important to realize that the selectivities in each cluster are unlikely to be extremely small, since most (if not all) of the equality conditions would have already been applied in the partitioning step. The remaining inequalities (such as `price<100`) may have selectivities distributed (not necessarily uniformly) across the whole $[0, 1]$ range.

The simplicity of the subscription language means that the functions `fj` are both cheap and small in number. Further, the functions that are actually executed in the inner loop are just pointer lookups: the code will look like `if (*r1[i]`

`&& *r2[i] ...`. This implementation is very similar to our dimension-table preprocessing example (context 3) in Section 3.1, with *every* function being treated in the same way.

We can reap two immediate benefits in terms of function specialization here. The first benefit is that all of the functions can be inlined, yielding very efficient code. The second, more subtle benefit is that we can get away with fewer pieces of code to implement all of the various candidate plans, because of the symmetry of the functions. For example, we can use the same subroutine to execute both the test `if (*r1[i] && *r2[i]) ...` and the "opposite" test `if (*r2[i] && *r1[i]) ...` by simply switching the positions of `r1` and `r2` in the parameter list when calling the subroutine.

The maximum number of subroutines we thus need to precompute is equal to the number of distinct normal form expressions when we consider all basic terms to be equivalent. A simple induction shows that for $n \geq 1$ basic terms we have 2^{n-1} such expressions. If we allow the No-Branch optimization, the number of expressions doubles, and the total is 2^n.

We expect in practice that the bulk of the subscriptions will have at most 6 basic expressions per subscription [16, 8]. Since the code for the inner loop is quite small, it is feasible to precompile all $2^1+2^2+\ldots+2^6 = 126$ code alternatives into the system, without using any sophisticated run-time code generation. For the small number of subscriptions having more than our predefined limit, we can use a generic loop. The generic loop will be more expensive per subscription than the specialized ones, but with few subscriptions of that form, the net cost will be small.

Based on the estimated selectivities, the best method for each group within each cluster can be determined off-line using the algorithm of Section 4.4. A function pointer can be stored with the sub-list to indicate which of the various plans should be used for this sub-list. (A permutation indicating the order of the arguments is also required.)

5.1 Validation

We validate our approach for an implementation consistent with the event notification scenario above. All functions `fi` are simple lookups in a corresponding character array `ti` of size 1000. Values in this array are either 1 or 0, set randomly according to a probability parameter p_i. The selectivities of each condition can thus be separately controlled.

We chose values for the cost model parameters that were consistent with both published reports [6, 1] and with the typical assembly code generated by `gcc`. The numbers for a Pentium III, measured in machine cycles, are: $r = 1$, $t = 2$, $l = 1$, $m = 17$, $a = 2$, $f_1 = \ldots = f_k = 1$.

In our first experiment, we show how the optimizer and the heuristic perform for four conditions when all probabilities are the same. This is the same scenario described by Figure 1. We ran many scans against a single cluster in memory, so that there is no cache miss penalty. Figure 2 shows the results for a 750 MHz Pentium III machine. The cost prediction of the optimizer is given as the solid line in the graph; the dotted line is the heuristic prediction. The actual performance numbers of all plans selected by the optimizer on some range are plotted as points. The order of the legend indicates the left-to-right ordering of ranges in which that plan was selected by the optimizer. In particular, the nobranch variant of the branching-and plan was optimal for $p \leq 0.14$; the nobranch variant of the `(1&2) && (3&4)` plan was selected from $p = 0.15$ to $p = 0.45$; the nobranch version of the `(1&2&3) && 4` plan was chosen for $p = 0.46$ through $p = 0.52$; for $p \geq 0.53$, the nobranch plan was chosen.

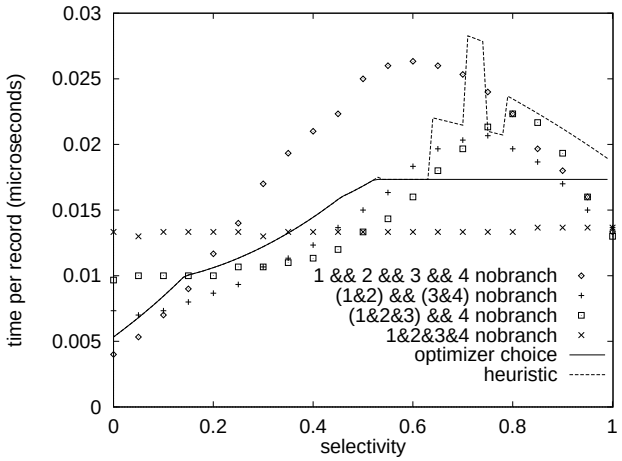

Figure 2: Prediction and actual performance.

For architecture-dependent reasons that we've already mentioned we don't expect our cost models to be exact cost estimates. Thus, we don't expect a perfect match of predicted cost with actual cost. The optimizer consistently overestimates the performance by about 20%. Nevertheless, the optimizer's choice is usually the best method for the given range.

To quantify how well our model measures branch misprediction, we compared the model's estimate of the number of mispredicted branches per record with the actual number of mispredictions. The actual number is obtained by using the hardware counters available on Pentium III processors to count the exact number of branch mispredictions; we used the "rabbit" tool to perform the actual counting [11]. The results for the branching-and plan, the plan having the most branches, are given in Figure 3. The closeness of the curves indicates that we are doing a good job of modeling branch misprediction.

The heuristic performs well except for high probabilities, when the no-branch algorithm is best. This observation suggests a simple modification to the heuristic algorithm: compare the result of the heuristic algorithm with the no-branch algorithm as a final step before choosing a plan.

In our second example, we consider a four-way conjunction in which the selectivities are unequal. The selectivity of the first condition is varied between 0 and 1, and is plotted on the x-axis. We let the second condition have a selectivity of

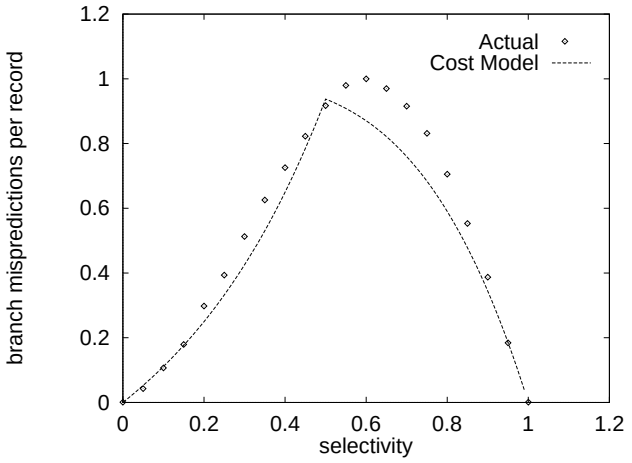

Figure 3: Branch misprediction count.

0.25, the third a selectivity of 0.5, and the fourth a selectivity of 0.75. Figure 4 shows the results. There are three plans

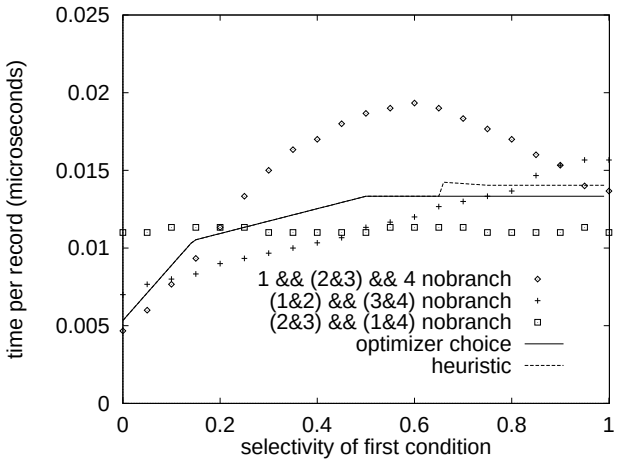

Figure 4: Unequal probabilities.

chosen by the optimizer in different ranges; the boundaries of those ranges are clear from the bumps in the optimizer selection curve. We see that when condition 1 is very selective, it appears on its own at the beginning of the test. When is it moderately selective, it is combined with the second condition. When it is not very selective, it appears at the right of the test. The heuristic performs adequately, although it gives plans about 10% worse than optimal for high probabilities.

5.2 Impact

We now try to measure the degree to which our techniques would affect the overall performance of subscription matching for Le Subscribe. Consider an example based on [8] in which there are six million subscriptions, and for which a number L of those subscriptions contain just inequality predicates. Because these subscriptions cannot be hash-partitioned, Le Subscribe would sequentially scan all L subscriptions for each event.

Using the parameter settings of [8], a default method would need between 12 and 45 nanoseconds per event per record. When L exceeds 150,000, i.e., 2.5% of the subscriptions, the cost of processing this subscription array (which is linear in L) dominates the overall cost. Our optimization techniques allow significant improvements (up to a factor of two) in this component of the cost. As a result, significant improvements in event throughput can be realized.

6. CONCLUSIONS

We have considered the problem of applying a conjunction of selection conditions to a large number of records in main memory. We have proposed a framework in which plans come from a space of plans representing combinations of three basic techniques. We have developed a cost model for plans that takes branch misprediction into account. We have developed a cost-based optimization technique using dynamic programming, for choosing among a space of plans, and have also developed a heuristic method of lower complexity. We have implemented an experimental case study based on a real-world event-notification system, and shown that significant performance gains can be achieved in that context.

The extent to which these kinds of performance gains can also be achieved in other kinds of query processing systems is highly dependent on the nature of their "inner loops." It is conceivable that many systems, including conventional database systems, have a relatively high overhead even for basic operations. For example, in order to handle arbitrary data types (possibly allowing null values) in a general way there may need to be some extra code in the inner loop. The benefits of our optimizations are significant only when the inner loops are tight, i.e., when the branch prediction overhead is a significant fraction of the total cost of the inner loop.

APPENDIX

A. COMPILING IF STATEMENTS

In `C`, there is a distinction between the use of `&` and `&&` in conditional tests. This is best understood by considering the translation of a `C` code fragment into assembly code. We show two `C` code fragments, one for each of `&` and `&&`, and show the corresponding pseudo-assembly code next to it. Assume that the integer variables `a` and `b` are in registers `ra` and `rb` respectively.

```
if (a&b) {          load        rc,ra
  <innercode>       and         rc,rb
}                   compare     rc,0
<body>              branch-eq   bodylabel
                    <innercode>
                  bodylabel:
                    <body>
```

```
if (a&&b) {         compare     ra,0
  <innercode>       branch-eq   bodylabel
}                   compare     rb,0
<body>              branch-eq   bodylabel
                    <innercode>
                  bodylabel:
                    <body>
```

For `&&`, if the first argument is zero, we branch immediately to the body code, without checking the second argument. For `&`, we perform a logical `and` of the two arguments, and then check for zero. The `&` code has one conditional branch, while the `&&` code has two. The code for `&` could potentially be optimized. For example, if there is no further need for one of `a` or `b` after the test, we could use one of those registers and omit the load into `rc`. On many machines, the logical `and` instruction automatically sets the condition codes, meaning that a separate compare with zero is not needed.

B. NON-INDEPENDENT SELECTIVITIES

For selectivities that are not independent, the dynamic programming method of Section 4.4 still applies. When optimizing the subplan for a subset S of the attributes, one assumes that all branches in the complement of S have succeeded. Thus for an attribute $A_i \in S$, we use the conditional selectivity $p_i|\bar{S}$, i.e., the selectivity that the test on A_i succeeds given that the tests on all attributes in the complement of S have succeeded.

Note that for non-independent selectivities, sub-optimization steps no longer generate optimal sub-plans for fewer attributes, since the selectivities are conditioned on attributes not appearing in the subplan. Also, it may be difficult to represent all of the conditional selectivities: there are exponentially many of them corresponding to different combinations of attributes S.

C. SUN RESULTS

The results for the experiment of Section 3.2 on a Sun UltraSparc are given in Figure 5. Unlike the Pentium, as the

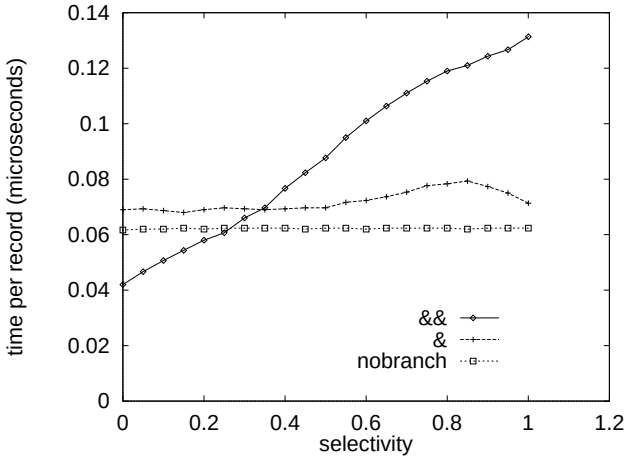

Figure 5: Three implementations: Sun.

selectivity approaches 1, the performance of the `&&` plan continues to worsen. The reason for this behavior is that the Sun can execute multiple instructions at a time. For the `&` algorithm and the nobranch algorithm, there are plenty of opportunities for executing multiple instructions in parallel. Instructions for the second test can be overlapped with instructions for the first, for example. However, in the `&&` algorithm there is much more dependence on the control flow, resulting in less effective parallelism. Taking such effects into account is a direction for future research. Note that even the first step of our approach (pulling up all instances of `&&` to the top level in Section 4.1) is not necessarily justified if subexpressions can be evaluated in parallel on a superscalar processor.

D. PREFETCHING AND FUNCTIONS

We need to address two important performance barriers: the cost of transferring data from RAM to the CPU cache, and the cost of evaluating functions. In this section we outline solutions to these barriers.

A potential performance problem is that we may have significant latency due to cache misses on the `r` arrays. After each cache-line's worth of entries from each `r` array is used, we have to wait until the next cache-line is brought into the cache from RAM. Given the tightness of the inner loop, this delay could be significant. This penalty can be reduced by employing *prefetching* [22, 6]. One instructs the processor to bring the `r` cache lines into the cache ahead of their actual use, using an explicit assembly language `prefetch` instruction. On a Pentium 4, the hardware *automatically* prefetches data ahead of its use for common access patterns, such as sequential access.

If we were to naively implement the code as written, we would need to execute a function call for each function evaluation. If the functions are known at compile time, they can be inlined, avoiding this overhead. Thus, if we know that certain "canned" queries are frequently posed, we can compile a single specialized loop for each one if we can derive estimates for the function cost and selectivity for the optimization algorithm. Since the loop code is small, we can probably tolerate thousands of such queries with a small expansion in the executable code size.

However, for ad-hoc queries we need to be able to allow the functions to be specified at run-time. There are two complementary problems. First, executing a function call (and potentially dereferencing a function pointer as well) may be a significant performance overhead in a tight inner loop. Secondly, we don't know the selectivities and function costs until query time, and these statistics are important for the selection of the appropriate inner-loop plan. There are several potential solutions to this problem. We outline one below.

When responding to an ad-hoc query, we still may have time to perform the optimization described above, compile a new version of the loop, with the appropriate combination of `&&`s and `&`s, and link it into the running code. Systems such as Tempo [5, 15] allow such run-time compilation. Run-time code specialization of this sort would be beneficial only if the optimization time plus the compilation time are smaller than the improvement in the running-time of the resulting plan. As we saw in Sections 4.4 and 4.5, the optimization time is relatively small. The code to be compiled is also relatively small. For scans of large tables, such an approach may indeed pay off.

THE NUMBER OF IRREDUCIBLE POLYNOMIALS AND LYNDON WORDS WITH GIVEN TRACE*

F. RUSKEY†, C. R. MIERS‡, AND J. SAWADA†

Abstract. The *trace* of a degree n polynomial $f(x)$ over $GF(q)$ is the coefficient of x^{n-1}. Carlitz [*Proc. Amer. Math. Soc.*, 3 (1952), pp. 693–700] obtained an expression $I_q(n,t)$ for the number of monic irreducible polynomials over $GF(q)$ of degree n and trace t. Using a different approach, we derive a simple explicit expression for $I_q(n,t)$. If $t > 0$, $I_q(n,t) = (\sum \mu(d)q^{n/d})/(qn)$, where the sum is over all divisors d of n which are relatively prime to q. This same approach is used to count $L_q(n,t)$, the number of q-ary Lyndon words whose characters sum to t mod q. This number is given by $L_q(n,t) = (\sum \gcd(d,q)\mu(d)q^{n/d})/(qn)$, where the sum is over all divisors d of n for which $\gcd(d,q)|t$. Both results rely on a new form of Möbius inversion.

AMS subject classifications. 05T06, 11T06

PII. S0895480100368050

1. Introduction.

The *trace* of a degree n polynomial $f(x)$ over $GF(q)$ is the coefficient of x^{n-1}. It is well known that the number of degree n irreducible polynomials over $GF(q)$ is given by

$$I_q(n) = \frac{1}{n}\sum_{d|n}\mu(d)q^{n/d}, \tag{1.1}$$

where $\mu(d)$ is the Möbius function. Less well known is the formula

$$I_2(n,1) = \frac{1}{2n}\sum_{\substack{d|n\\ d \text{ odd}}}\mu(d)2^{n/d}, \tag{1.2}$$

which is the number of degree n irreducible polynomials over $GF(2)$ with trace 1 (this can be inferred from results in Jungnickel [3, section 2.7]). One purpose of this paper is to refine (1.1) and (1.2) by enumerating the irreducible degree n polynomials over $GF(q)$ with a given trace. Carlitz [1] also solved this problem, arriving via a different technique at an expression that is different but equivalent to the one given below. Our version of the result is stated in Theorem 1.1.

THEOREM 1.1. *Let q be a power of prime p. The number of irreducible polynomials of degree $n > 0$ over $GF(q)$ with a given nonzero trace t is*

$$I_q(n,t) = \frac{1}{qn}\sum_{\substack{d|n\\ p\nmid d}}\mu(d)q^{n/d}. \tag{1.3}$$

‡Department of Mathematics and Statistics, University of Victoria, Clearihue Building, Room D268, 3800 Finnerty Road, Victoria, BC V8P 5C2, Canada (crmiers@math.uvic.ca).

Note that the expression on the right-hand side of (1.3) is independent of t and that $I_q(n,0)$ can be obtained by subtracting

$$I_q(n,0) = I_q(n) - (q-1)I_q(n,1).$$

A Lyndon word is the lexicographically smallest rotation of an aperiodic string. If $L_q(n)$ denotes the number of q-ary Lyndon words of length n, then it is well known that $L_q(n) = I_q(n)$. The *trace* of a Lyndon word is the sum of its characters mod q. Let $L_q(n,t)$ denote the number of Lyndon words of trace t. The second purpose of this paper is to obtain an explicit formula for $L_q(n,t)$. This result is stated in Theorem 1.2.

THEOREM 1.2. *For all integers $n > 0$, $q > 1$, and $t \in \{0,1,\ldots,q-1\}$,*

$$L_q(n,t) = \frac{1}{qn} \sum_{\substack{d|n \\ \gcd(d,q)|t}} \gcd(d,q)\mu(d)q^{n/d}.$$

Note that $I_q(n,t) = L_q(n,s)$ whenever $t \neq 0$ and $\gcd(n,s) = 1$. In order to prove Theorems 1.1 and 1.2 we need a new form of Möbius inversion. This is presented in the next section.

2. A generalized Möbius inversion formula. The defining property of the Möbius functions is

$$\sum_{d|n} \mu(d) \;=\; [\![n = 1]\!], \tag{2.1}$$

where $[\![P]\!]$ for proposition P represents the "Iversonian convention": $[\![P]\!]$ has value 1 if P is true and value 0 if P is false (see [4, p. 24]).

DEFINITION 2.1. *Let $\mathcal{R}$ be a set, $\mathbb{N} = \{1,2,3,\ldots\}$, and let $\{X(d,t)\}_{t\in\mathcal{R},d\in\mathbb{N}}$ be a family of subsets of $\mathcal{R}$. We say that $\{X(d,t)\}_{t\in\mathcal{R},d\in\mathbb{N}}$ is* recombinant *if*

(i) $X(1,t) = \{t\}$ *for all $t \in \mathcal{R}$ and*

(ii) $\{e' \in X(d',e) : e \in X(d,t)\} = \{e \in X(dd',t)\}$ *for all $d,d' \in \mathbb{N}, t \in \mathcal{R}$.*

THEOREM 2.2. *Let $\{X(d,t)\}_{t\in\mathcal{R},d\in\mathbb{N}}$ be a recombinant family of subsets of $\mathcal{R}$. Let $A : \mathbb{N}\times\mathcal{R} \to \mathcal{C}$ and $B : \mathbb{N}\times\mathcal{R} \to \mathcal{C}$ be functions, where $\mathcal{C}$ is a commutative ring with identity. Then*

$$A(n,t) = \sum_{d|n} \sum_{e\in X(d,t)} B\left(\frac{n}{d}, e\right)$$

for all $n \in \mathbb{N}$ and $t \in \mathcal{R}$ if and only if

$$B(n,t) = \sum_{d|n} \mu(d) \sum_{e\in X(d,t)} A\left(\frac{n}{d}, e\right)$$

for all $n \in \mathbb{N}$ and $t \in \mathcal{R}$.

Proof. Consider the sum, call it S, on the right-hand side of the first equation

$$\begin{aligned} S &= \sum_{d|n} \sum_{e\in X(d,t)} B\left(\frac{n}{d}, e\right) \\ &= \sum_{d|n} \sum_{e\in X(d,t)} \sum_{d'|(n/d)} \sum_{e'\in X(d',e)} \mu(d')A\left(\frac{n}{dd'}, e'\right) \\ &= \sum_{d|n} \sum_{dd'|n} \mu(d') \sum_{e\in X(d,t)} \sum_{e'\in X(d',e)} A\left(\frac{n}{dd'}, e'\right). \end{aligned}$$

Now substitute $f = dd'$ and use recombination to get

$$\begin{aligned}
S &= \sum_{d|n} \sum_{f|n} [\![f = dd']\!] \mu\left(\frac{f}{d}\right) \sum_{e \in X(d,t)} \sum_{e' \in X(d',e)} A\left(\frac{n}{f}, e'\right) \\
&= \sum_{f|n} \sum_{d|f} \mu\left(\frac{f}{d}\right) \sum_{e \in X(f,t)} A\left(\frac{n}{f}, e\right) \\
&= \sum_{f|n} \sum_{e \in X(f,t)} A\left(\frac{n}{f}, e\right) \sum_{d|f} \mu\left(\frac{f}{d}\right) \\
&= \sum_{f|n} \sum_{e \in X(f,t)} A\left(\frac{n}{f}, e\right) [\![f = 1]\!] \\
&= A(n,t).
\end{aligned}$$

Verification in the other direction is similar and is omitted. □

LEMMA 2.3. *Let $d \in \mathbb{N}$ and e, t be members of an additive monoid $\mathcal{R}$. The sets $\{e : de = t\}$ form a recombinant family.*

Proof. Here de means $e + e + \cdots + e$ (d terms). Suppose that $de = t$ and $d'e' = e$. Clearly, $dd'e' = t$. Conversely, if $dd'e' = t$, then $d'e'$ is equal to some element of $\mathcal{R}$, call it e. Then $d'e' = e$ and $de = t$. □

COROLLARY 2.4. *For a fixed prime power q, the sets $X_q(d,t) = \{e \in GF(q) : de = t\}$ form a recombinant family of subsets of $GF(q)$.*

COROLLARY 2.5. *For a fixed integer q, the sets $X_q(d,t) = \{e \in \mathbb{Z}_q : de \equiv t(q)\}$ form a recombinant family of subsets of $\mathbb{Z}_q$, where $\mathbb{Z}_q$ are the integers mod q.*

3. Irreducible polynomials with given trace. In this section, the irreducible polynomials with a given trace are counted. We begin by introducing some notation that will be used in the remainder of the paper. We use Jungnickel [3] as a reference for terminology and basic results from finite field theory.

The trace of an element $\beta \in GF(q^n)$ over $GF(q)$ is denoted $Tr(\beta)$ and is given by

$$Tr(\beta) = \beta + \beta^q + \beta^{q^2} + \cdots + \beta^{q^{n-1}}.$$

If $\beta \in GF(q^n)$ and d is the smallest positive integer for which $\beta^{q^d} = 1$, then $f(x)$ is the minimal polynomial of β, denoted $\mathrm{Min}(\beta)$, where

$$f(x) = (x - \beta)(x - \beta^q) \cdots (x - \beta^{q^{d-1}}).$$

The value of d must be a divisor of n.

Let $\mathbf{Irr}_q(n,t)$ denote the set of all monic irreducible polynomials over $GF(q)$ of degree n and trace t. By $a \cdot \mathbf{Irr}_q(n,t)$ we denote the multiset consisting of a copies of $\mathbf{Irr}_q(n,t)$. Classic results of finite field theory imply the following equality of multisets:

$$\bigcup_{\beta \in \mathrm{GF}(q^n)} \{\mathrm{Min}(\beta)\} = \bigcup_{d|n} d \cdot \mathbf{Irr}_q(d) = \bigcup_{d|n} \frac{n}{d} \cdot \mathbf{Irr}_q\left(\frac{n}{d}\right), \tag{3.1}$$

where $\mathbf{Irr}_q(d)$ is the set of monic irreducible polynomials of degree d over $GF(q)$. From (3.1) it is easy to derive (1.1) via a standard application of Möbius inversion.

Now we restrict the equality (3.1) to trace t field elements to obtain

$$\bigcup_{\substack{\beta\in \mathrm{GF}(q^n)\\ Tr(\beta)=t}} \{\mathrm{Min}(\beta)\} = \bigcup_{d|n} \frac{n}{d}\cdot\left\{f\in \mathbf{Irr}_q\left(\frac{n}{d}\right)\ :\ Tr(f^d)=t\right\} \tag{3.2}$$

$$= \bigcup_{d|n} \frac{n}{d}\cdot\left\{f\in \mathbf{Irr}_q\left(\frac{n}{d}\right)\ :\ d\cdot Tr(f)=t\right\} \tag{3.3}$$

$$= \bigcup_{d|n}\bigcup_{de=t} \frac{n}{d}\cdot\left\{f\in \mathbf{Irr}_q\left(\frac{n}{d}\right)\ :\ Tr(f)=e\right\} \tag{3.4}$$

$$= \bigcup_{d|n}\bigcup_{de=t} \frac{n}{d}\cdot\left\{f\in \mathbf{Irr}_q\left(\frac{n}{d},e\right)\right\}. \tag{3.5}$$

Note that the equation $de = t$ is asking whether the d-fold sum of $e \in GF(q)$ is equal to $t \in GF(q)$. We use the notation $GF(q^n, t)$ for the set of elements in $GF(q^n)$ with trace t, for $t = 0, 1, \ldots, q-1$, where $q = p^m$ and p is prime. Consider the map ρ that sends α to $\alpha + \gamma$, where $\gamma \in GF(q^n)$ has trace 1. We claim that $\rho(GF(q^n, t)) = GF(q^n, t+1)$, and so the number of elements is the same for each trace value. Thus

$$|GF(q^n, t)| = q^{n-1}.$$

Taking cardinalities in (3.5) gives

$$q^{n-1} = \sum_{d|n}\sum_{de=t} \frac{n}{d} I_q\left(\frac{n}{d}, e\right).$$

From Theorem 2.2 and Corollary 2.4, we obtain

$$I_q(n,t) = \frac{1}{qn}\sum_{d|n}\sum_{de=t} \mu(d) q^{n/d}.$$

The equation $de = t$ where d is an integer and $e, t \in GF(q)$ has a unique solution e if $t \neq 0$ and $p \nmid d$. If $t = 0$, then there is one solution $e = 0$ if $p \nmid d$ and there are q solutions if $p \mid d$. Thus, if $t \neq 0$, then

$$I_q(n,t) = \frac{1}{qn}\sum_{\substack{d|n\\ p\nmid d}} \mu(d) q^{n/d},$$

thereby proving Theorem 1.1. Otherwise, if $t = 0$, then

$$I_q(n,0) = I_q(n,1) + \frac{1}{n}\sum_{\substack{d|n\\ p\mid d}} \mu(d) q^{n/d}.$$

4. Lyndon words with given trace. If $\mathbf{a} = a_1 a_2 \cdots a_n$ is a word, then we define its trace mod q, $Tr_q(\mathbf{a})$, to be $\sum a_i \bmod q$. Let $L_q(n,t)$ denote the number of q-ary Lyndon words of length n and trace t mod q. Note that any q-ary string of length n can be expressed as the concatenation of d copies of the rotation of some Lyndon word of length n/d for some $d \mid n$. Note further that there are precisely q^{n-1}

words of length n with trace t because any word of length $n-1$ can have a final nth character appended in only one way to have trace t. It therefore follows that

$$q^{n-1} = \sum_{d|n} \sum_{de \equiv t(q)} \frac{n}{d} L_q\left(\frac{n}{d}, e\right). \tag{4.1}$$

This can be solved using Theorem 2.2 and Corollary 2.5 to yield

$$nL_q(n,t) = \sum_{d|n} \mu(d) \sum_{de \equiv t(q)} q^{n/d-1}.$$

Hence

$$L_q(n,t) = \frac{1}{qn} \sum_{\substack{d|n \\ \gcd(q,d)|t}} \gcd(q,d)\mu(d) q^{n/d}. \tag{4.2}$$

Equation (4.2) is true because $de \equiv t(q)$ has a solution if and only if $\gcd(d,q) \mid t$. If a solution exists, then it has precisely $\gcd(d,q)$ solutions (e.g., [2, Corollary 33.22, p. 821]). This proves Theorem 1.2.

We could also consider the more general question of computing $L_{q,r}(n,t)$, the number of q-ary Lyndon words with trace mod r, and derive similar but more complicated formulae. If $M_q(n,t)$ is the number of q-ary length n strings whose characters sum to t, then clearly $M_q(1,t) = [\![0 \le t < q]\!]$ and for $n > 1$

$$M_q(n,t) = \sum_{i=0}^{q} M_q(n-1, t-i).$$

If $T_{q,r}(n,t)$ denotes the number of q-ary length n strings with trace mod r equal to t, then

$$T_{q,r}(n,t) = \sum_{s \equiv t(r)} M_q(n,s).$$

Using the same approach as before

$$L_{q,r}(n,t) = \frac{1}{n} \sum_{d|n} \mu(d) \sum_{de \equiv t(r)} T_{q,r}\left(\frac{n}{d}, e\right).$$

The equation for $L_{q,r}(n,t)$ seems to produce no particularly nice formulae, except in the case seen previously where $q = r$ or if $q = 2$. When $q = 2$, $M_2(n,t) = \binom{n}{t}$ and

$$T_{2,r}(n,t) = \sum_{s \equiv t(r)} \binom{n}{s}.$$

However, in this case there is already a well-known formula for the number of Lyndon words with k 1's, namely,

$$P_2(n,k) = \frac{1}{n} \sum_{d|\gcd(n,k)} \mu(d) \binom{n/d}{k/d},$$

from which we obtain $L_{2,r}(n,t) = \sum_{s \equiv t(2)} P_2(n,s)$.

5. Final remarks. Our generalized Möbius inversion theorem can be extended to a Möbius inversion theorem on posets. Background material on Möbius inversion on posets may be found in Stanley [5]. We state here the modified definition of recombinant and the inversion theorem but omit the proof.

DEFINITION 5.1. *Let $\mathcal{P}$ be a poset, let $\mathcal{R}$ be a set, and let $\{X(y,x,t)\}_{x,y\in\mathcal{P},y\preceq x,t\in\mathcal{R}}$ be a family of subsets of $\mathcal{R}$. The family $\{X(y,x,t)\}_{x,y\in\mathcal{P},y\preceq x,t\in\mathcal{R}}$ is* recombinant *if*

(i) *$X(x,x,t)=\{t\}$ for all $t\in\mathcal{R}$ and*

(ii) *$\{e'\in X(z,y,e) : e\in X(y,x,t)\}=\{e\in X(z,x,t)\}$ for all $z\preceq y\preceq x\in\mathcal{P}, t\in\mathcal{R}$.*

We note that if $\mathcal{P}$ is the divisor lattice and $\mathcal{R}$ is an additive monoid, then the collection $\{X(x,y,t)\}_{x,y\in\mathcal{P},x\leq y,t\in\mathcal{R}}$ where $X(x,y,t)=\{e\in\mathcal{R} : (y/x)e=t\}$ is recombinant, as per Lemma 2.3.

THEOREM 5.2. *Let $\mathcal{P}$ be a poset, let $\mathcal{R}$ be a set, and let $\{X(y,x,t)\}_{x,y\in\mathcal{P},y\preceq x,t\in\mathcal{R}}$ be a recombinant family. Let $A:\mathcal{P}\times\mathcal{R}\to\mathcal{C}$, and $B:\mathcal{P}\times\mathcal{R}\to\mathcal{C}$, be functions where $\mathcal{C}$ is a commutative ring with identity. Then*

$$A(x,t)=\sum_{y\preceq x}\sum_{e\in X(y,x,t)}B(y,e)$$

for all $x\in\mathcal{P}$ and $t\in\mathcal{R}$ if and only if

$$B(x,t)=\sum_{y\preceq x}\mu(y,x)\sum_{e\in X(y,x,t)}A(y,e)$$

for all $x\in\mathcal{P}$ and $t\in\mathcal{R}$. (Here $\mu(y,x)$ is the Möbius function of the poset $\mathcal{P}$.)

Tables of the numbers $I_q(n,t)$ and $L_q(n,t)$ for small values of q and n may be found on Frank Ruskey's combinatorial object server (COS) at www.theory.csc.uvic.ca/~cos/inf/{lyndon.html,irreducible.html}. They also appear in Neil Sloane's on-line encyclopedia of integer sequences (at http://www.research.att.com/~njas/sequences/) as $I_2(n,0)=L_2(n,0)=$ A051841, $I_2(n,1)=L_2(n,1)=$ A000048, $I_3(n,0)=L_3(n,0)=$ A046209, $I_3(n,1)=L_3(n,1)=$ A046211, $L_4(n,0)=$ A054664, $I_4(n,1)=L_4(n,1)=$ A054660, $L_5(n,0)=$ A054661, $I_5(n,1)=L_5(n,1)=$ A054662, $L_6(n,0)=$ A054665, $L_6(n,1)=$ A054666, $L_6(n,2)=$ A054667, $L_6(n,3)=$ A054700.

Acknowledgment. The authors wish to thank Aaron Gulliver for helpful discussions regarding this paper.

Abstract : These seminar notes represent the proceedings (some in French) of a seminar devoted to the analysis of algorithms and related topics. The subjects covered include combinatorial models and random generation, symbolic computati- on, asymptotic analysis, average-case analysis of algorithms and data structures and some computational number theory.

Résumé : Ces notes de seminaires representent les actes, pour la plupart en anglais, d'un seminaire consacre a l'analyse d'algorithmes et aux domaines connexes. Les themes abordes comprennent : modeles combinatoires, generation aleatoire, calcul formel, analyse asymptotique, analyse en moyenne d'algorithmes et de structures de donnees, ainsi qu'un peu de theorie algorithmique des nombres.

Automatic Asymptotics and Generating Functions

Bruno Salvy
INRIA Rocquencourt

September 16, 1992

[summary by Bruno Salvy]

Abstract

Computer algebra systems can be of help in the asymptotic analysis of combinatorial sequences. Several algorithms are presented, most of which have been implemented in Maple.

Introduction

We assume a sequence is given, either by its first terms or by a combinatorial description of a class of objects it enumerates. The main tool we use is the *generating function* of the sequence. The idea is to consider this formal power series as an analytic function. When the series has a non-zero radius of convergence, Cauchy's theory makes it possible to find an asymptotic estimate of the sequence we started with.

1. From the sequence to the series

The preferred method naturally depends on the available information concerning the sequence.

Empirical method. When only the first few terms of the sequence are known, there are *a priori* an infinite number of possible sequences, and there seems to be little sense in looking for an asymptotic behaviour. However, there is quite often a "simple" sequence defined by these first terms. This approach was initiated by F. Bergeron and S. Plouffe [2], who looked for Padé approximants of the generating series. When the number of non-zero coefficients of the Padé approximant is "significantly" smaller than the number of given terms of the sequence, it is natural to conjecture that the generating series is rational and that a closed-form was found. This method can be extended by applying it to the logarithmic derivative or to the functional inverse of the given power series, which yields nice generating functions.

With P. Zimmermann, we applied this idea of looking for a "simple" generating function given its first coefficients to the quest of "holonomic" sequences, i.e. sequences satisfying a linear recurrence with polynomial coefficients. Rather than looking for a Padé approximant, this recurrence is sought by an undeterminate coefficients method. When the number of non-zero coefficients of the recurrence is "sufficiently" smaller than the number of given terms, the recurrence is conjectured as being satisfied by the whole sequence. This is implemented in the Gfun package [12].

Both these methods are very efficient in practice. Among the approximately 6000 sequences of the next edition of Sloane's book [14], roughly 25% of the sequences are thus conjectured rational, and an extra 5% are conjectured holonomic non-rational [9].

Combinatorial method. A large number of sequences f_n enumerate the number of objects of size n in some *decomposable* combinatorial data-structure. This means that the structure can be expressed in terms of a small combinatorial toolbox comprising cartesian product, disjoint union, list, set, cycle and basic atoms. Thus the structure "functional graph" (the graph of an application of a set of n elements into itself) is

expressed as a set of connected components, these components being cycles of trees, these trees themselves being recursively defined as the cartesian product of a node (the root of the tree) by a set of trees.

The $\Lambda\Upsilon\Omega$ system, developed jointly with P. Zimmermann and Ph. Flajolet [3, 4] implements a translation of these combinatorial specifications into equations relating the corresponding generating functions. In the example of functional graphs, the first part of the system will produce the following equations:

$$\mathrm{FuncGraph}(z) = \exp(\mathrm{comp}(z)), \quad \mathrm{comp}(z) = \log[1/(1-\mathrm{tree}(z))], \quad \mathrm{tree}(z) = z\,\exp(\mathrm{tree}(z)).$$

A second part of the system then attempts to find an explicit form of the generating function from this system. For, in its current state, the asymptotic part of the $\Lambda\Upsilon\Omega$ system can only handle explicit generating functions. In this example, thanks to Maple's W function, the following "explicit" form is obtained:

$$\frac{1}{1+W(-z)}.$$

Conclusion. Two very different methods have been described to obtain the generating function of a sequence. The first one finds *holonomic* generating functions, i.e. solutions of linear differential equations with polynomial coefficients. The second one is more combinatorial and finds generating functions that obey functional equations expressed in terms of some "elementary" functions. In some cases, these equations can be solved.

Known algorithms to get "explicit" forms from these equations can be summarised as follows.

- Liouvillian solutions of linear differential equations can be obtained by Kovacic's algorithm for the case of order 2. This algorithm is (at least partially) implemented in most computer algebra systems. An algorithm due to M. Singer treats the general case, but is not practical. The third order has been made practical by F. Ulmer, but there is no generally available implementation;
- Hypergeometric solutions of linear differential equations can be found by an algorithm due principally to M. Petkovšek, without any limitation on the order of the equation [8];
- Elementary functional equations can only be solved in some special cases.

2. From generating functions to asymptotics

When the generating series defines an analytic function, Cauchy's formula yields the nth Taylor coefficient as

$$[z^n]f(z) = \frac{1}{2i\pi}\oint \frac{f(z)}{z^{n+1}}dz.$$

The path of integration is a closed contour containing the origin and no other singularity.

We are looking for an asymptotic estimate as n tends to infinity. First of all, Hadamard's rule implies that the coefficients grow roughly as $1/R^n$, where R is the radius of convergence. This relates the exponential growth of the Taylor coefficients of a generating function to the location of its singularities. Besides, simple functions whose coefficients are known, such as $1/(1-z)^\alpha$, give the intuition that sub-exponential growth of the coefficients is related to the local growth of the generating function in the neighbourhood of its singularity of smallest modulus. This can be made precise.

2.1. Singularity analysis. In 1878, G. Darboux treated the case of algebraic singularities. This result was extended by R. Jungen in 1934 to handle singularities in $(1-z)^\alpha \log^k(1-z)$, where k is a non-negative integer. Finally, Ph. Flajolet and A. Odlyzko [5] described the more general case where the exponents of $(1-z)$ and of the logarithm are complex numbers. These methods yield a full asymptotic expansion of the Taylor coefficients.

This leads to the following algorithm to find the asymptotic expansion of coefficients of a generating function.

(1) Locate the singularities of smallest modulus;
(2) Compute the expansion of the function in the neighbourhood of these singularities;
(3) Translate this expansion into the expansion of the coefficients.

The last step above is easy. We now insist on how the first two steps can be automated. This depends on the type of equation defining the generating function.

When the generating function is given as a solution to a linear differential equation, its singularities are found among the poles of the coefficients of the equation and the roots of its leading coefficient. Since the coefficients are polynomials, singularities in this case are therefore algebraic numbers. When the generating function is given explicitly in terms of elementary functions, it is easy to find a set of points containing the singularities by a recursive algorithm.

Then one has to compare the moduli of the singularities. Algebraic numbers can be compared by purely algebraic methods using resultants and Sturm sequences. It is also possible to make use of guaranteed numerical estimates, see [6]. In the more general case of elementary constants one is confined to heuristics, the problem being related to difficult questions of transcendency.

Once the dominant singularities have been located, one looks for the local behaviour of the generating function in the neighbourhood of these singularities. When the function is given explicitly as an exp-log function (functions built up from $\mathbb{Q}$ and x by field operation, exp and $x \mapsto \log|x|$), a recent algorithm due to J. Shackell [13] makes it possible to compute the local expansion. When the generating function is holonomic, the possible behaviours have been given by E. Fabry in 1885, and have the form

$$\exp[P(1/(1-(z/\rho)^{1/d}))](1-z/\rho)^{\alpha}\sum_{k=0}^{K}\phi_k(z)\log^k(1-z/\rho),$$

where ϕ_k are formal power series in $1-z/\rho$. Such local solutions can be determined automatically [15]. Once a basis of local solutions has been found, one has to find the right linear combination in terms of the first elements of the sequence. While these elements are given by the Taylor expansion of the function at the origin, we have a basis of local solutions at the singularity. Besides, the formal power series ϕ_k are generally divergent. One must then resort to the theory of resummation [1].

2.2. Saddle-point method. When the function is entire or has a singularity of a more "violent" type than a mere algebraico-logarithmic type, it is often possible to use a saddle-point method. Setting $h(z) = \log(f(z)) - (n+1)\log z$, the contour of Cauchy's integral is deformed to pass through a point (*the saddle-point*) where $h'(z) = 0$. With a few extra hypotheses, Cauchy's integral is then concentrated in the neighbourhood of the saddle-point and the integral can be approximated by a Gaussian. If we denote the saddle-point by R, the nth coefficient is then estimated as

$$[z^n]f(z) \approx \frac{f(R)}{R^{n+1}\sqrt{2\pi h''(R)}}.$$

To automate this method and the approximations it requires, one uses a theorem due to W. K. Hayman [7], which makes it possible to decide sufficient conditions under which the method applies. A last technical problem is that the saddle-point is often only available as an asymptotic expansion deduced from the equation $h'(R) = 0$. An algorithm to compute this expansion under very general conditions has been developed in [11].

Abstract :
The paper deals with systems of ODEs containing polynomial nonlinearities and random inhomogeneous terms. Applying perturbation method pathwise solutions are found in form of power series with respect to a parameter eta controlling the nonlinearities. Under the assumption that for eta=0 the system is stable and that the inhomogeneous terms are bounded the radius of convergence of the perturbation series is estimated. Further, it is proved that the perturbation series form stationary solutions if the inhomogeneous terms are stationary.

Robust Text Analysis via Underspecification

Frank Schilder*

Department for Informatics
Vogt-Kölln-Str. 30
22527 Hamburg
Germany

Abstract

This paper is concerned with the robust analysis of the discourse structure of a text via underspecification. Most current discourse theories (e.g. Rhetorical Structure Theory (RST) by Mann and Thompson (1988), Abduction by Hobbs *et al.* (1993) or Segmented Discourse Representation Theory (SDRT) by Asher (1993)) require detailed world and context knowledge for the derivation of the discourse structure. A discourse structure for a given text has to be obtained in every case. For an ambiguous discourse a high number of structures may be generated.

The present approach instead derives an *underspecified* discourse structure for text based on a limited set of discourse cues. Only when evidence for a discourse relation or a set of discourse relations is given, for example, via a discourse marker is the discourse structure further specified.

After providing background information on underspecification and SDRT, a general framework of an underspecified discourse grammar is outlined. This framework captures scope ambiguities of discourse relations, introduces to the SDRT representation the underspecification of the discourse relation that links two segments, and further specifies the content of an abstract topic node that dominates a segment.

1. Introduction

A robust processing of text that results in the text's discourse structure is not easy to achieve. Even a small and relatively simple text presupposes an extensive body of world knowledge. The derivation of the discourse structure, however, can be useful for many text processing tasks such as automatic text summarising, text retrieval and information extraction. Hence a robust, but not too thorough analysis of a text can help to improve these tasks. So far most current discourse theories presuppose a rich knowledge representation system including an inference machine. Hence robustness is only very rarely found in discourse theories which is partly due to the complexity of the theoretical undertaking. Many questions in discourse processing are still unsolved, such as anaphora resolution.

*Many thanks to Christie Manning for her help and support.

A few studies that try to aim at a more robust derivation of the rhetorical structure of a text have already been carried out. Marcu (1999), for example, employs decision-based learning techniques for rhetorical parsing. A crucial prerequisite for the success of the parser, however, is a discourse corpus tagged with rhetorical and semantic information. Unfortunately, there is still a lack of such corpora and compiling these corpora is quite work intensive and time-consuming.

In addition to the need to have more robust text processing tools for Natural Language Processing tasks such as summarising, a robust and seemingly shallow modelling of discourse processing may more accurately mirror what humans do while reading a text. A reader can grasp the gist of an article even when only skimming it. On reading the same article again the reader may build a more detailed representation of the article's structure and content, but it is questionable whether she will ever build up a complete and fully specified discourse structure. In contrast, current discourse theories specify that every single segment has to be put into a hierarchical order regarding the rest of the text. There is no empirical evidence that human readers actually do such a thing and certainly they do not do it as thoroughly as current discourse theories predict. On the contrary, studies on discourse annotation, as well as psycholinguistic research, suggest that readers do not always fully specify the discourse structure and anaphoric relations within a text.

A study on discourse annotation by (Marcu *et al.*, 1999), for example, suggests that human annotators of text employ a wait-and-see-approach while tagging text according to discourse structure. Log files created during their empirical studies showed that the annotators simultaneously maintained a high number of unrelated parts of discourse. This finding contradicts the view that a newly processed discourse unit is immediately incorporated in the discourse structure derived so far. Psychological investigations also show that readers do not always specify in every detail what the rhetorical structure of a text is.[1]

Hence, the main assumption of this paper is that the discourse structure should not, and even cannot always be precisely determined. The hierarchical structure that all current discourse theories assume cannot be pinned down as concretely as these theories demand. Instead, the discourse structure is only partly spelled out. There may be some passages in the text that can be fully specified with respect to the discourse structure, but other parts of the texts may not. There the discourse structure is left *underspecified*.

In this paper, the underspecification of the discourse structure is used to develop a general framework for discourse processing. Such a framework provides a base for a system that derives a formalisation in every case, even when crucial knowledge sources are not available. Consequently, the system draws heavily on underspecification techniques as they have already been successfully employed for the semantic analysis of sentences.

So far, only a few studies have been carried out on applying underspecification formalisms to discourse grammars (Gardent & Webber, 1998; Schilder, 1998). The current paper goes beyond these approaches by focusing on the underspecified representation of all possible discourse relations. Also discussed is how the topic information covering a more concise and abstract representation of larger text spans can be incorporated into the representation. Moreover, a method for specifying an upper bound of all conceivable readings is provided before a description of a preliminary implementation and an example derivation are discussed. Finally, future extensions of the framework and the implementation are discussed in the conclusion.

[1] See Garrod and Sanford (1985) for experiments on underspecified anaphoric references.

2. Background

This section provides some background information on underspecification techniques used in sentence and discourse semantics as well as a concise introduction to SDRT. SDRT has been chosen as the basic formal framework for the given approach, because it offers a high degree of formal machinery for capturing a wide variety of discourse phenomena including discourse attachment and constraints on anaphora resolution. For a robust text analysis, however, this rich formalism is rather a hindrance. Nevertheless, it may be useful to work within such a formal framework where robust techniques on drawing inferences on world knowledge can be incorporated as soon as they are developed. The general approach taken by this paper is to leave out parts of the theory that are computationally unattractive, but allow them to be substituted by robust methods at a later time.

2.1. Underspecification

Underspecification formalisms provide a formal system that can be used for the concise representation of more than one reading for an ambiguous sentence such as (1):

(1) Every man loves a woman.

The logical form may be

a. $\forall x \exists y\ man(x) \rightarrow (woman(y) \wedge love(x, y))$, or

b. $\exists y \forall x\ man(x) \rightarrow (woman(y) \wedge love(x, y))$

Within an underspecification formalism such as the hole-semantics proposed by Bos (1995) a representation is derived that leaves open the ordering between the two quantifiers. This is done by ordering constraints between sub-formulae (i.e. $\leq$ holding for sub-formulae of the Predicate Logic). Figure 1 reflects this partial ordering between sub-formulae.

More precisely, the ordering constraints hold between labels. Note that the sub-formulae in figure 1 are labelled either as a *hole* (e.g. h_o) or a *plug* (e.g. l_1). Resolving the representation means filling the *holes* (i.e. h_0, h_1, h_2) with *plugs* (i.e. l_1, l_2, and l_3).[2]

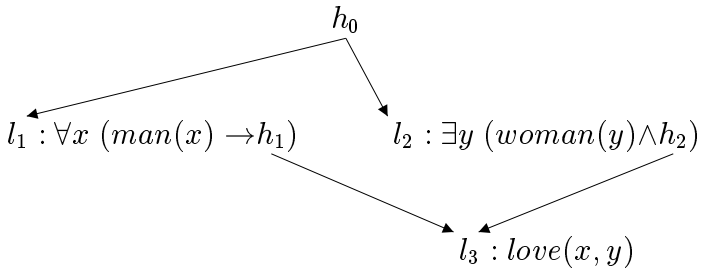

Figure 1: Two formulae can be derived from this underspecified representation

Similarly, discourse grammars have been developed that also allow underspecification. Here the scope of the to-be-derived rhetorical relations may be left open. Consider (2):

[2]There are two conceivable pluggings for the underspecified representation in figure 1: (a) $h_0 = l_1 \wedge h_1 = l_2 \wedge h_2 = l_3$ and (b) $h_0 = l_2 \wedge h_1 = l_3 \wedge h_2 = l_1$.

(2) (a) I try to read a novel (b) if I feel bored or (c) I am unhappy. (Gardent & Webber, 1998)

The discourse in (2) is ambiguous with respect to the expressed discourse structure. Either the speaker tries to read a novel provided one of the two conditions in (b) and (c) hold or the speaker tries to read a book *or* she is unhappy. As Gardent and Webber (1998) show, these two readings can be represented by leaving the structural relations between scope-bearing discourse relations underspecified. A formal representation is presented in figure 2. A tree logic is used to represent several trees in one representation (i.e. forest) instead of one tree for each reading, by employing dominance constraints on node labels similar to the ordering constraints for the hole-semantics. Such constraints on node labels are imposed indicating the strict dominance relation or the dominance relation, which is transitive. The strict dominance relation (i.e. parent relation) is drawn with a straight line, whereas the dominance relation is indicated by the dotted line.[3]

The forest representation in figure 2 can give rise to the following specified readings: (i) *a if (b or c)* or (ii) *(a if b) or c*.

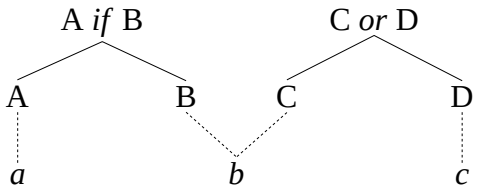

Figure 2: The underspecified discourse structure for (2).

2.2. Segmented Discourse Representation Theory (SDRT)

SDRT can be seen as a natural extension of DRT (Kamp & Reyle, 1993). Within DRT Discourse Representation Structures (DRSs) are defined as pairs $\langle U, C \rangle$, with U a (finite and possibly empty) set of discourse referents, and C a (finite) set of conditions. A shortcoming of DRT is that longer discourse are represented as a conjunction of conditions. No hierarchical structure between different discourse segments can be captured by DRT. SDRT, on the other hand, allows segmental information to be added via discourse relations. Similar to a DRS, an SDRS is defined as a pair $\langle \mathcal{U}, \mathcal{C} \rangle$, with $\mathcal{U}$ a (finite) set of discourse segments, and $\mathcal{C}$ a (finite) set of SDRS conditions. Those conditions on $\mathcal{U}$ are obtained by applying a discourse relation to the discourse segments from $\mathcal{U}$.

It is important to note that the definition of an SDRS is recursive. The universe $\mathcal{U}$ consists of discourse segments which are either DRSs (i.e. basic case) or again SDRSs. Following Asher (1996) DRSs and SDRSs will be labelled ($\{K_1, \ldots, K_n\}$). Labels will become more important for the underspecified version of SDRT. But let us first present the formal recursive definition of an SDRS given as a pair of sets containing labelled DRSs or SDRSs, and the discourse relations holding between them.

[3]The two different approaches (i.e. hole-semantics and underspecification via dominance relations) are different ways to express underspecification. Using dominance relations is a more general way to capture underspecification, since the differentiation between holes and labels is not necessary.

Definition 1 (SDRS) *Let $K_1 : \alpha_1 \ldots K_n : \alpha_n$[4] be a labelled DRSs or SDRSs and R a set of discourse relations. The tuple $\langle \mathcal{U}, \mathcal{C} \rangle$ is an SDRS if*

(a) $\mathcal{U}$ is a labelled DRS and $\mathcal{C} = \emptyset$ or

(b) $\mathcal{U} = \{K_1 \ldots, K_n\}$ and $\mathcal{C}$ is a set of SDRS conditions. An SDRS condition is a discourse relation such as $D(K_1, \ldots, K_n)$, where $D \in R$.

For the basic case (i.e. $\langle K, \emptyset \rangle$) K labels a DRS representing the semantic context of a sentence:

(3) Pedro owns a donkey.

K :

$x\ y\ s$
Pedro(x) donkey(y) owns(s,x,y)

A clause that contains a verb constitutes a segment. For two segments a discourse relation has to be derived that furthermore introduces a hierarchical ordering indicated by a graph representation. Within this graph the nodes are the labelled SDRSs and the edges are discourse relations. Apart from the discourse relations, which impose the hierarchical ordering, 'topic' relations add more internal structure to this graph. If a sentence α is the topic of another sentence β, this is formalised as $\alpha \Downarrow \beta$.[5] This symbol also occurs in the graph, indicating a further SDRS condition. The graph representation illustrates the hierarchical structure of the discourse and in particular the open attachment site for newly processed sentences. Basically the constituents on the so-called 'right frontier' of the discourse structure are assumed to be available for further attachment (cf. Webber (1991)).[6]

As mentioned earlier, SDRT exploits discourse relations to establish a hierarchical ordering of discourse segments. How the discourse relations such as *Narration* or *Elaboration* are derived is left to an axiomatic theory called DICE (DIscourse in Commonsense Entailment) that uses a non-monotonic logic. Formally, this theory is expressed by means of the Comonsense Entailment (CE) (Asher & Morreau, 1991).

Taking the reader's world knowledge and Gricean-style pragmatic maxims into account, DICE provides a formal theory of discourse attachment. The main ingredients are defaults describing laws that encode the knowledge we have about the discourse relation and discourse processing. Two such laws are given here as an example for giving an impression of the type of information that has to be formalised:

Narration A common 'topic' is required for the two sentences α and β. It is the preferred relation for narrative texts and hence inferred by default if other information is not given.

[4] Greek symbols are normally used to described the semantic representation of sentences.

[5] A further SDRS condition is *Focus Background Pair* (FBP) which is introduced by *background*.

[6] See Asher (1996, p. 24) for a formal definition of openness in SDRT.

Elaboration The event described by the second sentence β is a part of the event of the first one α.

It may be concluded from this brief description of the theory's main ingredients that even for a rather short text an extensive body of world knowledge has to be encoded to feed the non-monotonic reasoning system. There has been some discussion within this theoretical framework to what extend this load of encoding common sense can be partly avoided. A proposal by Asher and Fernando (1997) employs underspecification. However, this proposal does not address the question of how an underspecified topic may look or how all conceivable readings can be derived for a given underspecified representation. In particular, the open attachment points for an underspecified DRS are not described.

Another extension of SDRT in Schilder (1998) gives a precise definition of the open attachment points by using a tree logic based on tree description grammar by Kallmeyer (1996). The Underspecified SDRT (USDRT), however, does not allow the underspecification of the discourse relation that links two segments, nor is the number of all conceivable readings for a given underspecified representation defined.

Both approaches lack especially a specification on how discourse markers may constrain an underspecified SDRS. Within the SDRT framework, only little work has been done on how discourse marker may constrain the derivation of the discourse structure.

3. Underspecification and discourse processing

The starting point of the current proposal to a robust discourse grammar is the underspecified version of SDRT (Asher, 1993) defined in (Schilder, 1998) called USDRT. In the following section, a further development to this theory is presented which outlines new treatments regarding (a) the underspecification of the discourse relation(s), (b) the determination of the topic within the discourse structure and (c) the derivation of the maximal number of conceivable readings for a given underspecified representation.

After formally defining an underspecified discourse structure, different ways of constraining the structure according to discourse clues are discussed in section 3.2. A short description of a partial implementation of the formalism as well as a derivation of an example discourse are given.

3.1. Underspecification via tree descriptions

The proposed formalism employs a tree logic that allows a concise representation of all conceivable discourse tree structures. Analogous to other approaches to underspecification (e.g. (Reyle, 1993; Bos, 1995; Pinkal, 1996)), the underspecification between the sub-formulae (i.e Segmented Discourse Representation Structures (SDRSs)[7]) is expressed by labels and the (immediate) dominance relations that hold between these labels specify the ordering between daughter nodes. The definition of an underspecified USDRS is as follows (cf. (Schilder, 1998)):

[7]The semantic content of a sentence is represented by a DRS, larger sequences by an SDRS.

Definition 2 (USDRS) *Let S be a set of DRSs, L a set of labels, $\mathcal{R}$ a set of discourse relations. Then U is a USDRS confined to the tuple $\langle S, L, \mathcal{R} \rangle$ where U is a finite set consisting of conditions of the following form:*

- *structural information*
  - *immediate dominance relation: $K_1 \lhd K_2$, where $K_1, K_2 \in L$*
  - *dominance relation: $K_1 \lhd^* K_2$, where $K_1, K_2 \in L$*
  - *precedence relation: $K_1 \prec K_2$, where $K_1, K_2 \in L$*
  - *equivalence relation: $K_1 \approx K_2$, where $K_1, K_2 \in L$*
- *content information*
  - *sentential (i.e. universe): $s_1 : \alpha$, where $s_1 \in L, \alpha \in S$*
  - *segmental (i.e. conditions):*
    - *discourse relation(s) connecting two segments: $K_{R1} : relation(\mathcal{P}, K'_{R1}, K''_{R2})$, where $\mathcal{P} \subseteq \mathcal{R}$, and K_{R1}, K''_{R1}, and $K''_{R1} \in L$*
    - *topic information: $K^{\mathcal{T}}_{R1} : \mathcal{T} \subseteq \{\alpha, \beta\}$*

A USDRS consists on the one hand of content information specifying the DRSs and the conditions imposed on them. In contrast to the original definition of USDRT, a discourse relation *set* $\mathcal{P}$ provides the link between (S)DRSs. Former approaches to underspecification of discourse structure (Asher & Fernando, 1997; Schilder, 1998) do not provide an appropriate formalisation for the underspecification of the discourse relations. These approaches deal with underspecified discourse relations in the same way as scope ambiguity. However, there is a crucial difference between these two forms of ambiguity: scope ambiguity can easily be resolved by computing all combinations of scope-bearing operators. The discourse relations, on the other hand, cannot be resolved by determining the scope of all relations. The relations have to be inferred from world knowledge and the information provided by the context.

Within the standard SDRT account, only one relation must be obtained by considering world knowledge as well as additional discourse knowledge. Applying this system leads to a disambiguation of the given discourse with all conceivable readings. The SDRT approach is problematic with respect to the following two aspects. Firstly, the non-monotonic reasoning system comes with computational costs that one may not want to bear. Secondly, deriving all readings for an ambiguous discourse could be computationally intractable, since all conceivable readings are derived. Hence, any derivation within the modified version of USDRT presented here starts with a structure as shown in figure 3.[8]

In the following, important features of this underspecified representation are described in more detail.

3.1.1. Underspecified discourse relations.

In the case that the discourse relation is not known for two segments then $\mathcal{P} = \mathcal{R}$. After taking into account further restrictions, only a subset of discourse relations is possible. The underspecification of the discourse relation set $\mathcal{R}$ is expressed via a lattice structure. The set

[8] The description for the tree is $K_\top \lhd^* K^{\mathcal{T}}_{R1} \wedge K^{\mathcal{T}}_{R1} \lhd K_{R1} \wedge K_{R1} \lhd K'_{R1} \wedge K_{R1} \lhd K''_{R1} \wedge K'_{R1} \lhd^* s_1 \wedge K''_{R1} \lhd^* s_2$.

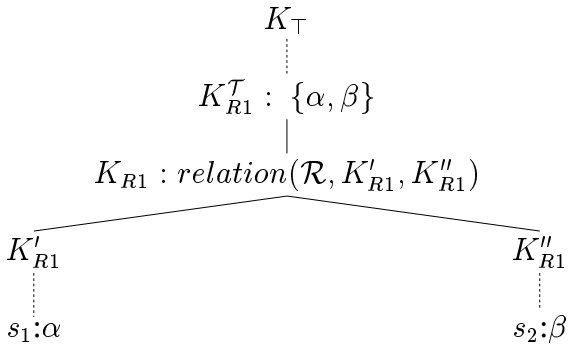

Figure 3: Underspecified discourse structure

of the relations can therefore easily be constrained by means of an intersection operation. The ordering of the discourse relation lattice for the four relations *Narration, Result, Elaboration* and *Explanation,* for example, can be found in figure 4.

There has been some discussion of how many discourse relations there are. The number of relations proposed by different approaches to discourse range from two (Polanyi, 1988) to as many as needed (Mann & Thompson, 1988). Still, the successful application of the current proposal does not depend on the outcome of this discussion. For an actual implementation only a subset of relations may be chosen including, for instance, *Explanation*. The output of such a system would miss many relations and dependencies expressed by the text, but still be able to cover at least all causal relations that hold between the described situations.[9]

For the theoretical considerations and the constraints on anaphora resolution two relation sets are particularly important: the subordinating relation set $\overline{\mathcal{S}}$ (e.g. *Narration*) and the subordinated relation set $\underline{\mathcal{S}}$ (e.g. *Elaboration*). A relation from the latter set allows attachment to both discourse segments, whereas the former set consists of relations that close off the preceding discourse.

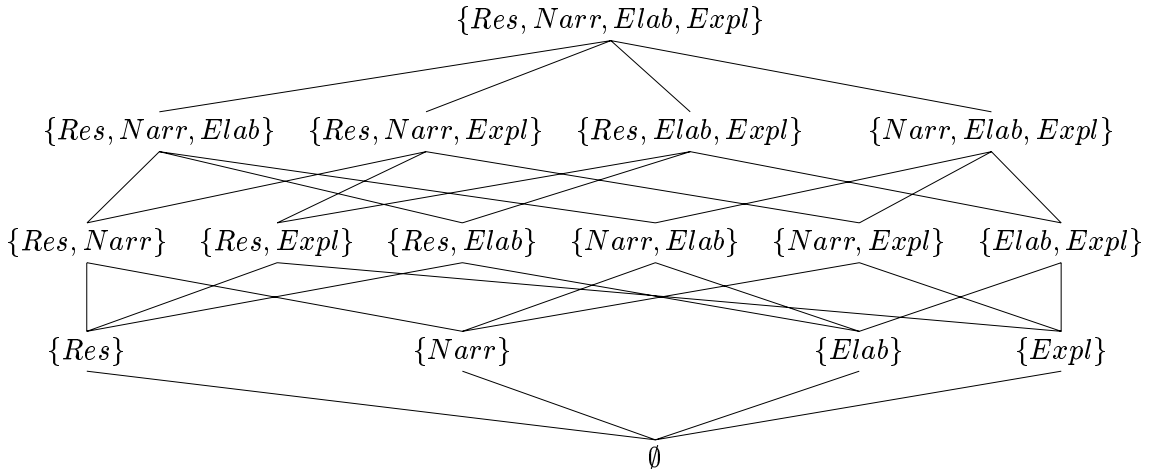

Figure 4: The discourse relation lattice for four discourse relations

[9]The number of used discourse relations is currently being further investigated. A starting point for this investigation is the work on discourse clues by Knott (1996).

3.1.2. Topic information

The topic node plays an important role for the discourse representation. It contains information in an abstract form as to what the given segment is about. Note that the usage of the term topic has varied widely in the literature. Some researchers (e.g. (Sgall *et al.*, 1986; Büring, 1997)) understand topic as a part of a sentence indicated by the linguistic surface structure. The topic structure to be investigated by the current paper, however, goes beyond the surface structure and covers larger text spans.

The definition of a common topic (i.e. $\Downarrow$) was already introduced by standard SDRT, but only as a further restriction regarding discourse attachment. I adopt the topic node as defined in Schilder (1998). In this case, the topic node is given as an additional feature for every segment.[10] However, it is not entirely clear what this node contains. For a first approximation on the content of the topic node, two types of discourse structures for two segments α and β are distinguished:

1. a subordinating structure is triggered by discourse relations such as *Narration* or *Result*. These relations close off the preceding discourse. Consequently, only the last mentioned segment β is accessible for the following discourse and the topic node gets filled by it.

2. a subordinated structure is derived for discourse relations such as *Elaboration* or *Explanation*. Here both segments remain open for attachment, the topic node gets filled by the first segment α.

Additionally, I allow a third (preliminary) discourse structure that also has an effect on the topic node:

3. a coordinated structure does not distinguish between the two segments. Both segments end up in the topic node (cf. figure 3).

The question of how to specify the topic node is the subject of other current research. For the time being, the node can contain these three types of sets reflecting (1) a subordinating, (2) a subordinated or (3) a coordinated structure. The last structure is also applied when the discourse structure is left underspecified.

3.1.3. Derivation of all readings

Note that for an underspecified representation the number of conceivable readings grows quite rapidly. Ten clauses connected via nine discourse relations have 4862 different discourse tree structures. The number of all conceivable readings can be computed via the Catalan number:[11] $C_n = \frac{(2n)!}{(n+1)!n!}$. The Catalan number provides the solution for an extensive body of combinatorial problems. The number C_n describes, for instance, the maximal number of rooted binary trees with n internal nodes. Binary trees are also the representation of the discourse structure described by USDRT with the exemption of having an additional internal topic node. Note that the discourse relation(s) always relate *two* segments. Hence the number of possible discourse structures for *n* discourse relations is C_n.

[10] The value of the topic node can be compared to the nucleus in RST.

[11] See Sloane, N. J. A. Sequences A000108/M1459 in "An On-Line Version of the Encyclopedia of Integer Sequences." `http://www.research.att.com/~njas/sequences/eisonline.html`

In addition to the discourse *tree* structure, USDRT also determines the content of the node. For a fully specified discourse structure, one specific discourse relation can be derived. The number of possible readings therefore depends on the number of discourse relations. Consequently, the total number for a discourse structure containing of n discourse relations sets (i.e. internal nodes) is $C_n \times \mid \mathcal{R} \mid^n$.

Proof 1 (sketch) The maximal number of discourse structures for a USDRS with $n+1$ segments connected via n discourse relations is determined by the Catalan number C_n. Assuming that $\mathcal{R}$ is the set of all conceivable discourse relations, there are at most $C_n \times \mid \mathcal{R} \mid^n$ different discourse trees.

We show via induction that every underspecified discourse structure of n clauses can be translated into a rooted binary tree with n leaves. Remember that the Catalan number gives the number of possible trees for a given rooted binary tree with $n+1$ leaves:

The top node $\top$ is the root of the given tree. SDRSs as defined in Definition 1 are binary tree structures, because the discourse relation possesses only two arguments. Consequently, we obtain C_n different discourse structures for $n+1$ clauses.

Finally, it has to be shown that the $relation$ node can vary with respect to the derived discourse relation. For $\mid \mathcal{R} \mid$ possible discourse relations, there are $\mid \mathcal{R} \mid^n$ different ways of assigning a discourse relations to the n internal $relation$ nodes: by assigning a unique number out of $\{1, \ldots, \mid \mathcal{R} \mid\}$ to every relation in $\mathcal{R}$, the internal nodes of the discourse structure can be represented as a $\mathcal{R}$-nary number. There are $\mid \mathcal{R} \mid^n$ different numbers for a given $\mathcal{R}$-nary number of length n.

3.2. Constraining the underspecified representation

There are several steps for determining a more specified representation of the discourse structure. First, all discourse units have to be extracted. Discourse units are clauses that contain a verbal phrase or are separated by punctuation.[12] Second, the discourse structure is built. This can be done with different degrees of specification.

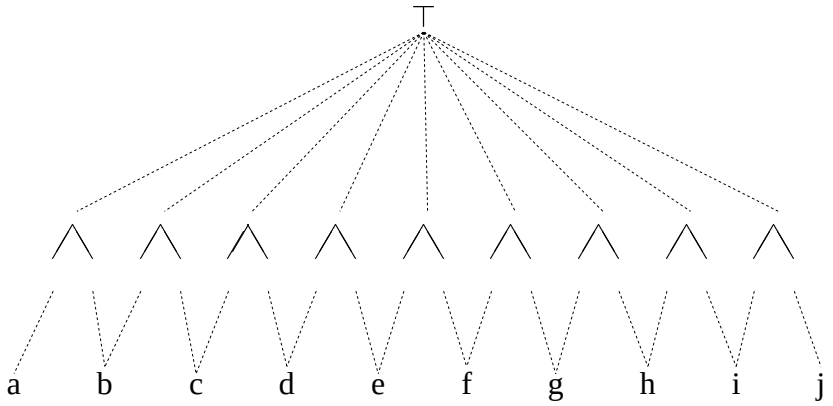

Figure 5: the discourse structure underspecified

[12]The definition of a discourse unit varies among discourse theories. More research is needed here to determine precisely what a discourse unit constitutes. The current definition is only a working hypothesis.

1. **Total underspecification.** Discourse units are connected via the set of all possible rhetorical relation $\mathcal{R}$. However, no restriction is given here and hence the number of readings that is covered by the representation grows according to the Catalan number. The underspecified tree structure figure 5 allows for $4862 \times \mid \mathcal{R} \mid^{9}$ different readings.

2. **Underspecification restricted by discourse markers.** The totally underspecified representation can be further restricted when discourse clues are taken into account.

3. **(Partial) resolution via world knowledge.** Finally, the discourse structure can be resolved, or partially resolved, or to different degrees restricted, provided the appropriate world and background knowledge is available.[13] How far the structural ambiguities can be eliminated depends on how well the encoded theory covers world and background knowledge.

Clearly, for a robust processing only total underspecification or underspecification restricted by discourse markers are available. However, future developments on robust processing of world knowledge can easily be incorporated.

3.2.1. Implementation

The proposed discourse theory has been partly implemented. First, a discourse grammar taking into account punctuation and discourse clues determines the discourse units and has as an output a USDRS.[14] In the following some rules are named in Definite Clause Grammar (DCG) notation.

```
%% a discourse grammar fragment (without discourse semantics)
%% in DCG notation
%%
%% a discourse may be a sentence or a question.
d(P2) --> s(P2).
d(P2) --> q(P2).

%% a discourse consists of
%% a discourse clue <discourse marker|empty>,
%% a clause,
%% a discourse clue <discourse marker|(punctuation, discourse marker)|empty>,
%% and  another disourse
d --> dclue(D), cl, D, d.

% a sentence
s --> cl, fullstop.

% a question
q --> cl, questionmark.

fullstop --> ['.'].
questionmark --> ['?'].
```

[13] Certain types of domain-specific knowledge would be fairly easy to formalise.

[14] The current implementation, however, does not consider all clues that could constrain the discourse structure. Those clues are to be determined on the result of an extensive corpus study.

```
%% a clause consists of words
cl --> words.
words --> word, words.
words --> [].

%% a word must not be a punctuation sign or a discourse marker
word --> [W],{<not a punctation sign or a discourse marker>}.

% lexicon look up
dclue(D)--> {lexicon(dclue,Word,D)}, Word.

%% lexicon
lexicon(dclue,['Contrary', to],[',']).
lexicon(dclue,[],['.', 'Yet']).
...
```

The discourse semantics is derived during the parse of the discourse. The tree descriptions are encoded in the following way:

```
td(<Holes>, <Trees>, <Dominance>)
```

`<Holes>` is a list that contains the set of labels that dominate other labels (e.g. h in $l \lhd^* h$) and can be "plugged" by an appropriate other label. `<Trees>` is a list of fully specified trees presented in the following general form:

```
<Mothernode>/[<Daughter1>,...,<DaughterN>].
```

Remember that the nodes are also labelled (e.g. `T1:Topic/R1:relation(R)/[K1,K2]`). And finally the dominance constraints for the tree description can be found in `<Dominance>` (e.g. `leq(K1,T2)`). Given this representation, all conceivable readings are calculated by using Bos' plugging algorithm (Bos, 1995).[15]

3.2.2. Underspecified derivation

Let us now go through an example text and derive an underspecified representation for the given discourse structure.

(4) (a) CONTRARY to some headlines at the end of last week, (b) America's stock-market bubble has not burst. (c) Yet the market turmoil has prompted one topical economic question: (d) how much might a crash hurt America's economy?

(e) The answer of many American optimists is that (f) a slump in share prices would not trigger a recession, (g) because the real economy is fundamentally so sound. (h) *It* is, (i) *they* argue, much healthier than Japan's in the late 1980s or East Asia's economies in the mid-1990s, just before their bubbles burst. (j) It is certainly true that America has much to boast about: [...] (source: *The Economist*)

[15] A more efficient algorithm such as recently proposed by (Koller *et al.*, 2000) could easily be adopted for the implementation.

The totally underspecified representation for the given text can be found in figure 5. There are ten clauses connected via nine discourse relation sets. This rather short segment allows already for $4862\times \mid \mathcal{R} \mid^{9}$ different discourse structures.

To restrict this number, discourse clues and punctuation signs are taken into account. In sequence (4) the discourse clues are underlined. The first clause contains the marker *contrary to*. This discourse cue phrase expresses a contrast.[16] Hence the discourse relation *Contrast* is derived for the relation set connecting the first two clauses. According to the constraints on openness defined by SDRT, this relation closes off preceding discourse segments. Consequently, the second clause (4b) ends up in the topic node.

The next clause (4c) also contains a discourse cue that expresses a contrast (i.e. *Yet*). Again the discourse relation *Contrast* can be derived.

The next clue we can get comes from the punctuation. The double column indicates an explanation in the given context. However, there are other contexts where the double column triggers a direct speech instead. Since other indicators (e.g. quotes) are missing, the relation *Explanation* can be determined for (4c+d).

For the following clause (4e) no discourse cue can be found. Accordingly, the set of all conceivable discourse relations $\mathcal{R}$ is assigned to connect (4d) and (4e).

The entire sentence (4e-f), that consists of three clauses, exhibits the same scope ambiguity as already analysed by Gardent and Webber for example sequence (2). Note that although the discourse cue *because* triggers an *Explanation* relation, the attachment site is underspecified (see figure 6).

After considering the discourse cues in (4a-g), the resulting underspecified discourse structure represents $4\times \mid \mathcal{R} \mid^{6}$ different readings. Originally, this part of the example sequence could have had $132\times \mid \mathcal{R} \mid^{6}$ different discourse structures.

Finally, I would like to highlight the influence of the discourse structure on the set of possible antecedents for anaphoric expressions. Note that the conceivable antecedents for the pronouns *it* and *they* in (4h) and (4i) are still accessible (i.e. *America's economy* in (4d)/*the real economy* in (4g) and *American optimists* in (4e)).

4. Conclusions and further directions

The current paper has shown how an underspecified representation of discourse structure can provide a robust representation format for text analysis. A text is first analysed as an underspecified discourse structure of $n + 1$ clauses connected by n discourse relation sets. It was also shown that the number of possible readings can be computed by the Catalan number C_n. The totally underspecified representation can furthermore be further restricted by the discourse cues found in the text.

Summarising, an underspecified version of SDRT (Schilder, 1998) was extended and the following features were added:

- Underspecifying the conceivable discourse relations via a lattice structure

[16] Considering Knott's taxonomy there are several kinds of coherence relations expressing a contrast. For the time being only a very general *Contrast* relation is assumed following the SDRT account that does not make a finer distinction.

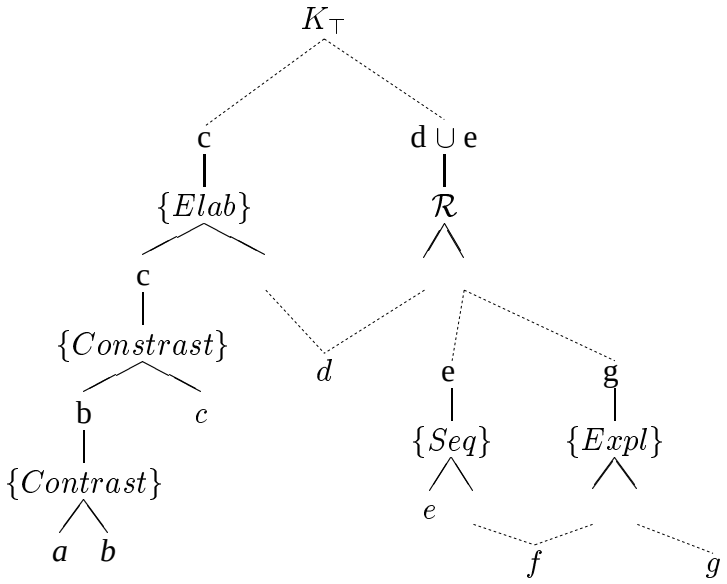

Figure 6: the discourse structure partially resolved according to discourse markers

- Restricting the set of possible readings by discourse cues

Directions of current and future work are:

- The contribution of cue phrases, especially punctuation and formatting cues (e.g. section, paragraph formatting)
- The relationship between the underspecified discourse structure and the set of possible antecedents for anaphoric expressions
- The determination of the topic for a given text segment

February 5, 2002 – REVISED

Abstract

In this article, I suggest that calculus instruction should include a wider variety of examples of convergent and divergent series than is usually demonstrated. In particular, a number of convergent series, such as $\sum_{k\geq 1} \frac{k^3}{2^k}$, are considered, and their exact values are found in a straightforward manner. We explore and utilize a number of mathematical topics, including manipulation of certain power series and recurrences.

During my most recent spring break, I read William Dunham's book *Euler: The Master of Us All* [3]. I was thoroughly intrigued by the material presented and am certainly glad I selected it as part of the week's reading.

Of special interest were Dunham's comments on series manipulations and the power series identities developed by Euler and his contemporaries, for I had just completed teaching convergence and divergence of infinite series in my calculus class. In particular, Dunham [3, p. 47-48] presents Euler's proof of the Basel Problem, a challenge from Jakob Bernoulli to determine the

exact value of the sum $\sum_{k\geq 1} \frac{1}{k^2}$. Euler was the first to solve this problem by proving that the sum equals $\frac{\pi^2}{6}$.

I was reminded of my students' interest in this result when I shared it with them just weeks before. I had already mentioned to them that exact values for relatively few families of convergent series could be determined. The obvious examples are geometric series $\sum_{k\geq 0} r^k$ (with $|r| < 1$) and telescoping series. I also remembered their disappointment when I observed that the exact numerical value of most convergent series cannot be determined in a straightforward way. I tried to excite them with the notion that the convergence or divergence of a given series could be determined via the Integral Test, Limit Comparison Test, Ratio or Root Test, but this was received with little enthusiasm.

But now I return to Dunham's book. In [3, p. 41], Dunham notes that Jakob Bernoulli [2, p. 248-249] proved

$$\sum_{k\geq 1} \frac{k^2}{2^k} = 6 \tag{1}$$

and

$$\sum_{k\geq 1} \frac{k^3}{2^k} = 26. \tag{2}$$

Many teachers of calculus will recognize at least two things about (1) and (2). First, these series are made-to-order examples to demonstrate convergence with the Ratio Test. Such examples, where the summands are defined by the ratio of a polynomial and an exponential function, can be found in a number of calculus texts, such as [4] and [5]. Second - a much more negative admission - is that we rarely teach students how to prove equalities like (1) and (2). We usually stop at demonstrating that such series converge, and move on to other matters. This is the case with the two calculus texts mentioned above, and it is an unfortunate situation to say the least.

I contend that students of first-year calculus would be better served if we provided a few more tools to them for finding **exact** values of convergent infinite series. Oddly enough, the series in (1) and (2) are ideal for such a task.

My goal in this note is to present two approaches to finding the exact value of

$$a(m,n) := \sum_{k\geq 1} \frac{k^n}{m^k}$$

with $|m| > 1$ and $n \in \mathbb{N} \cup \{0\}$ (of which Bernoulli's examples (1) and (2) are special cases).

We begin by noting that, for each $|m| > 1$, $\left|\frac{1}{m}\right| < 1$, so that $a(m,0)$ is a convergent geometric series. Moreover,

$$\begin{aligned} a(m,0) &= \sum_{k\geq 1} \frac{1}{m^k} \\ &= \frac{1}{m} + \sum_{k\geq 2} \left(\frac{1}{m}\right)^k \\ &= \frac{1}{m} + \frac{1}{m}\sum_{k\geq 1} \left(\frac{1}{m}\right)^k \\ &= \frac{1}{m} + \frac{1}{m} a(m,0). \end{aligned}$$

Solving for $a(m,0)$, we see that it equals $\frac{1}{m-1}$. Of course, this result easily follows from the usual formula for the sum of a convergent geometric series.

Next, we obtain a recurrence for $a(m,n),\ n \geq 1$, in terms of $a(m,j)$ for $j < n$. Note that

$$\begin{aligned} a(m,n) &= \sum_{k\geq 1} \frac{k^n}{m^k} \\ &= \frac{1}{m} + \sum_{k\geq 2} \frac{k^n}{m^k} \\ &= \frac{1}{m} + \frac{1}{m}\sum_{k\geq 1} \frac{(k+1)^n}{m^k} \\ &= \frac{1}{m}\left[1 + \sum_{k\geq 1} \frac{(k+1)^n}{m^k}\right]. \end{aligned}$$

The argument up to this point is exactly that used in finding the formula for $a(m,0)$ above. We now employ the binomial theorem, a tool that should be in the repertoire of first-year calculus students.

$$\begin{aligned} a(m,n) &= \frac{1}{m}\left[1+\sum_{k\geq 1}\frac{\left(\sum_{j=0}^{n}\binom{n}{j}k^j\right)}{m^k}\right] \\ &= \frac{1}{m}\left[1+\sum_{j=0}^{n}\binom{n}{j}\sum_{k\geq 1}\frac{k^j}{m^k}\right] \\ &= \frac{1}{m}\left[1+\sum_{j=0}^{n-1}\binom{n}{j}\sum_{k\geq 1}\frac{k^j}{m^k}+\sum_{k\geq 1}\frac{k^n}{m^k}\right] \\ &= \frac{1}{m}\left[1+\sum_{j=0}^{n-1}\binom{n}{j}a(m,j)+a(m,n)\right] \\ &= \frac{1}{m}a(m,n)+\frac{1}{m}\left[1+\sum_{j=0}^{n-1}\binom{n}{j}a(m,j)\right] \end{aligned}$$

Solving for $a(m,n)$ yields

$$\left(1-\frac{1}{m}\right)a(m,n)=\frac{1}{m}\left[1+\sum_{j=0}^{n-1}\binom{n}{j}a(m,j)\right]$$

or

$$a(m,n)=\left(\frac{1}{m-1}\right)\left[1+\sum_{j=0}^{n-1}\binom{n}{j}a(m,j)\right]. \tag{3}$$

As a sidenote, it is interesting to see from (3) that, for rational values of m, the numerical value of $a(m,n)$ must be rational for all $n \geq 0$. This can be proven via induction on n. We noted above that $a(m,0)=\frac{1}{m-1}$ which is rational as long as m is rational. Then, assuming $a(m,j)$ is rational for $0 \leq j \leq n-1$, (3) implies $a(m,n)$ is also rational. Hence, no values such as $\frac{\pi^2}{6}$ will arise as values for $a(m,n)$ whenever m is rational.

The recurrence in (3) can be used to calculate with relative ease the **exact** value of

$$a(m,n)=\sum_{k\geq 1}\frac{k^n}{m^k}$$

for all $|m| > 1$ and $n \in \mathbb{N} \cup \{0\}$. For example, since

$$a(2,0) = \sum_{k \geq 1} \frac{1}{2^k} = 1,$$

we have

$$\begin{aligned} a(2,1) &= \sum_{k \geq 1} \frac{k}{2^k} \\ &= \left(\frac{1}{2-1}\right)\left[1 + \binom{1}{0} a(2,0)\right] \\ &= 1 + 1 = 2, \end{aligned}$$

and

$$\begin{aligned} a(2,2) &= \sum_{k \geq 1} \frac{k^2}{2^k} \\ &= 1 + \binom{2}{0} a(2,0) + \binom{2}{1} a(2,1) \\ &= 1 + 1 + 2 \cdot 2 = 6, \end{aligned}$$

which is the result labeled (1). Finally,

$$\begin{aligned} a(2,3) &= \sum_{k \geq 1} \frac{k^3}{2^k} \\ &= 1 + \binom{3}{0} a(2,0) + \binom{3}{1} a(2,1) + \binom{3}{2} a(2,2) \\ &= 1 + 1 + 3 \cdot 2 + 3 \cdot 6 = 26, \end{aligned}$$

which is (2).

Of course, recurrence (3) could be used to calculate $a(m,n)$ for larger values of m and n. However, this might prove tedious for extremely large values of n. With this in mind, we now approach the calculation of $a(m,n)$ from a second point of view.

We begin with the familiar power series representation for the function $\dfrac{1}{1-x}$:

(4) $$\frac{1}{1-x} = 1 + x + x^2 + x^3 + x^4 + \ldots, \text{ where } |x| < 1$$

Andrews [1] recently extolled the virtues of (4) in the study of calculus. Our goal in this section is to manipulate (4) via differentiation and multiplication to obtain a new power series of the form

$$f_n(x) := x + 2^n x^2 + 3^n x^3 + 4^n x^4 + \ldots = \sum_{k\geq 1} k^n x^k$$

for a fixed positive integer n. This is done by applying the $x\frac{d}{dx}$ operator to $\frac{1}{1-x}$ n times. Then $a(m,n)$ equals $f_n\left(\frac{1}{m}\right)$, which is easily computed once $f_n(x)$ is written as a rational function. (Note that we define $f_0(x)$ by $f_0(x) := x\left(\frac{1}{1-x}\right) = \sum_{k\geq 1} x^k$.)

As an example, we apply the $x\frac{d}{dx}$ operator to $\frac{1}{1-x}$ and get

$$x\frac{d}{dx}\left(\frac{1}{1-x}\right) = x\frac{d}{dx}(1 + x + x^2 + x^3 + x^4 + \ldots)$$

or

$$f_1(x) = \frac{x}{(1-x)^2} = x + 2x^2 + 3x^3 + 4x^4 + \ldots = \sum_{k\geq 1} kx^k.$$

Hence,

$$\sum_{k\geq 1} \frac{k}{2^k} = f_1\left(\frac{1}{2}\right) = \frac{\frac{1}{2}}{\left(1-\frac{1}{2}\right)^2} = 2.$$

We can apply the $x\frac{d}{dx}$ operator to $\frac{1}{1-x}$ twice to obtain $f_2(x)$:

$$\begin{aligned} f_2(x) &= x\frac{d}{dx}\left(x\frac{d}{dx}\left(\frac{1}{1-x}\right)\right) \\ &= x\frac{d}{dx}\left(\frac{x}{(1-x)^2}\right) \\ &= \frac{x^2+x}{(1-x)^3}. \end{aligned}$$

Thus,

$$f_2(x) = \frac{x^2+x}{(1-x)^3} = x + 2^2x^2 + 3^2x^3 + 4^2x^4 + \ldots = \sum_{k\geq 1} k^2x^k.$$

Hence,

$$\sum_{k\geq 1}\frac{k^2}{2^k} = f_2\left(\frac{1}{2}\right) = \frac{\frac{1}{2}+\left(\frac{1}{2}\right)^2}{\left(1-\frac{1}{2}\right)^3} = 6$$

upon simplification. This, as we have already seen, is (1).

Additional applications of the $x\frac{d}{dx}$ operator can be performed to yield

$$\begin{aligned}
f_1(x) &= \frac{x}{(1-x)^2} = \sum_{k\geq 1} kx^k,\\
f_2(x) &= \frac{x^2+x}{(1-x)^3} = \sum_{k\geq 1} k^2x^k,\\
f_3(x) &= \frac{x^3+4x^2+x}{(1-x)^4} = \sum_{k\geq 1} k^3x^k,\\
f_4(x) &= \frac{x^4+11x^3+11x^2+x}{(1-x)^5} = \sum_{k\geq 1} k^4x^k,\\
f_5(x) &= \frac{x^5+26x^4+66x^3+26x^2+x}{(1-x)^6} = \sum_{k\geq 1} k^5x^k, \text{ and}\\
f_6(x) &= \frac{x^6+57x^5+302x^4+302x^3+57x^2+x}{(1-x)^7} = \sum_{k\geq 1} k^6x^k.
\end{aligned}$$

We see that

$$f_n(x) = \frac{g_n(x)}{(1-x)^{n+1}}$$

for each $n \geq 1$ where $g_n(x)$ is a certain polynomial of degree n. Indeed, the functions $g_n(x)$ are well-known. Upon searching N.J.A. Sloane's On-Line Encyclopedia of Integer Sequences [6] for the sequence

$$1, 1, 1, 1, 4, 1, 1, 11, 11, 1, 1, 26, 66, 26, 1, \ldots,$$

which is the sequence of coefficients of the polynomials $g_n(x)$, we discover that these are the **Eulerian numbers** $e(n, j)$. They are defined, for each value of j and n satisfying $1 \leq j \leq n$, by

(5) $e(n, j) = je(n-1, j) + (n-j+1)e(n-1, j-1)$ with $e(1, 1) = 1$.

With this notation, it appears that, for $n \geq 1$,

$$f_n(x) = \frac{\sum_{j=1}^{n} e(n,j)x^j}{(1-x)^{n+1}}.$$

Using (5), this assertion can be proven in a straightforward manner via induction. Moreover, we know from [6, Sequence A008292] that

$$e(n,j) = \sum_{\ell=0}^{j} (-1)^\ell (j-\ell)^n \binom{n+1}{\ell}.$$

This can be used to write the rational version of $f_n(x)$ for any $n \geq 1$ in a timely way. So, for example, we see that

$$f_8(x) = \frac{x^8 + 247x^7 + 4293x^6 + 15619x^5 + 15619x^4 + 4293x^3 + 247x^2 + x}{(1-x)^9},$$

which implies

$$\sum_{k\geq 1} \frac{k^8}{5^k} = f_8\left(\frac{1}{5}\right) = \frac{1139685}{2048}.$$

We have thus seen two different ways to compute the exact value of $\sum_{k\geq 1} \frac{k^n}{m^k}$ with $|m| > 1$ and $n \in \mathbb{N} \cup \{0\}$, one with a recurrence and one with power series. I encourage us all to share at least one of these techniques with our students the next time we are exploring infinite series.

FACTORIAL FACTORS

John R. Silvester
Department of Mathematics
King's College London

Preliminaries: the product of n successive positive integers is divisible by $n!$. For if we choose n elements from a set of order m, where $m \quad n$, we may choose the first element m ways, the second $m \quad 1$ ways, and so on, giving

$$m(m \quad 1)(m \quad 2)\ldots(m \quad n+1)$$

possible (ordered) choices. If we make one choice equivalent to another when its elements are a permutation of the elements of the other, we separate the set of choices into equivalence classes of $n!$ elements each, so that

$$\frac{m(m \quad 1)(m \quad 2)\ldots(m \quad n+1)}{n!}$$

is the number of possible (unordered) choices of n objects from m. This is also written $\binom{m}{n}$ or ${}^{m}C_{n}$, and is the coefficient of x^n in the (binomial) expansion of $(1+x)^m$.

Here is a hoary old problem that reappears every Christmas:

According to the song, how many presents did my true love send to me?

(N.B. A partridge in a pear tree counts as *one* present.)

Let (r, s, t) denote the r^{th} present of type s received on the t^{th} day of Christmas.

So, for example, $(3, 5, 8)$ stands for the 3^{rd} of the 5 gold rings received on the 8^{th} day.

We must count all integer triples (r, s, t) with

$$1 \leq r \leq s \leq t \leq 12,$$

or (equivalently)

$$1 \leq r < s' < t'' \leq 14$$

(where s' means $s+1$, and t'' means $t+2$), and so the answer is

$$\binom{14}{3} = \frac{14 \times 13 \times 12}{3!} = 364.$$

A simpler problem: evaluate $1 + 2 + 3 + \ldots + n$.

Solution (by counting): write it as

$$(1) + (1 + 1) + (1 + 1 + 1) + \ldots + (1 + 1 + \ldots + 1)$$

where the last bracket contains n 1's. Then let (r, s) denote the r^{th} 1 in the s^{th} bracket. We must count all integer pairs (r, s) with

$$1 \leq r \leq s \leq n,$$

or (equivalently)

$$1 \leq r < s' \leq n + 1,$$

and so the answer is

$$\binom{n+1}{2}.$$

Thus

$$\sum_{r=1}^{n} r = \binom{n+1}{2}$$

or, more suggestively,

$$\sum_{r=1}^{n} \binom{r}{1} = \binom{n+1}{2}, \quad \text{or} \quad \sum_{r=0}^{n} \binom{r+1}{1} = \binom{n+2}{2}.$$

In the partridge-in-a-pear-tree problem, the number of presents received on day s was $1+2+\ldots+s=\binom{s+1}{2}$, so the solution amounted to saying that

$$\sum_{s=1}^{12}\binom{s+1}{2}=\binom{14}{3},\quad\text{or}\quad\sum_{s=0}^{11}\binom{s+2}{2}=\binom{11+3}{3}.$$

In fact, for any n,

$$\sum_{s=0}^{n}\binom{s+2}{2}=\binom{n+3}{3},$$

and more generally (as we shall prove next)

$$\sum_{s=0}^{n}\binom{s+k}{k}=\binom{n+k+1}{k+1}.$$

Proof: note first that $\binom{s+k}{k}$ is the number of ways of choosing integers a_1, a_2, ..., a_k with $1 \leq a_1 < a_2 < \ldots < a_k \leq s+k$, or

$$1 \leq a_1 < a_2 < \ldots < a_k < s+k+1.$$

Put $a_{k+1} = s+k+1$, and then as s runs from 0 to n, altogether we get the number of ways of choosing a_1, a_2, ..., a_k, a_{k+1}, with

$$1 \leq a_1 < a_2 < \ldots < a_k < a_{k+1} \leq n+k+1,$$

and this is just $\binom{n+k+1}{k+1}$, as required.

Alternative proof: we have

$$1 + y + y^2 + \ldots + y^{n+k} = \frac{y^{n+k+1} \quad 1}{y \quad 1},$$

and on putting $y = 1 + x$ this becomes

$$1 + (1 + x) + (1 + x)^2 + \ldots + (1 + x)^{n+k} = \frac{(1 + x)^{n+k+1} \quad 1}{x}.$$

The result follows on comparing coefficients of x^k on each side.

More applications: note that

$$s^2 = \binom{s}{2} + \binom{s+1}{2}. \qquad (\star)$$

This is pretty obvious anyway; but can be seen by counting.

We must count all (a, b) with $1 \leq a \leq s$ and $1 \leq b \leq s$.

For each such pair (a, b) we have

$$a < b \quad \text{or else} \quad b \leq a,$$

so we have

$$1 \leq a < b \leq s \quad \text{or else} \quad 1 \leq b < a' \leq s + 1,$$

which give the first and second terms of $(\star)$, respectively.

From ($\star$) we have

$$\begin{aligned}
\sum_{s=1}^{n} s^2 &= \binom{n+1}{3} + \binom{n+2}{3} \\
&= \frac{(n+1)n(n \quad 1)}{6} + \frac{(n+2)(n+1)n}{6} \\
&= \frac{n(n+1)\ (n \quad 1) + (n+2)}{6} \\
&= \frac{n(n+1)(2n+1)}{6}.
\end{aligned}$$

Alternatively,

$$\begin{aligned}
4\sum_{s=1}^{n} s^2 &= \sum_{s=1}^{n} (2s)^2 \\
&= \sum_{s=1}^{n} \binom{2s}{2} + \binom{2s+1}{2} \\
&= \sum_{s=2}^{2n+1} \binom{s}{2} \\
&= \binom{2n+2}{3} \\
&= \frac{(2n+2)(2n+1)(2n)}{6},
\end{aligned}$$

so now divide each side by 4.

Now for the cubes. s^3 is the number of ways of choosing (p, q, r) with $1 \leq p \leq s$, $1 \leq q \leq s$, and $1 \leq r \leq s$.

Case 1: $|\{p, q, r\}| = 3$, that is, p, q, r are distinct. This now subdivides into $3! = 6$ cases according to the relative sizes of p, q, and r: for example, one case is $1 \leq p < q < r \leq s$, and the total count for case 1 is $6 \binom{s}{3}$.

Case 2: $|\{p, q, r\}| = 2$, so that two of p, q, r are equal, but different from the third. We can choose the two that are equal in 3 ways, and then the third is either greater or less than the others, so again there are 6 cases; for example, one is $1 \leq p = q < r \leq s$, and the total count for case 2 is $6 \binom{s}{2}$.

Case 3: $|\{p, q, r\}| = 1$, or $p = q = r$, so that $1 \leq p = q = r \leq s$, and the count here is just s, or $\binom{s}{1}$.

So

$$s^3 = 6\binom{s}{3} + 6\binom{s}{2} + \binom{s}{1},$$

and therefore

$$\sum_{s=1}^{n} s^3 = 6\binom{n+1}{4} + 6\binom{n+1}{3} + \binom{n+1}{2}.$$

We shall show, *by counting*, that this is the same as

$$\left(\sum_{s=1}^{n} s\right)^2,$$

so that its value is

$$\frac{n^2(n+1)^2}{4}.$$

Recall that $1 + 2 + \ldots + n$ is the number of pairs (a, b) with $1 \leq a < b \leq n+1$. So $(1+2+\ldots+n)^2$ is the number of 4-tuples (a, b, c, d) with $1 \leq a < b \leq n+1$ and $1 \leq c < d \leq n+1$.

Case 1: $|\{a, b, c, d\}| = 4$. There are 6 subcases:

$$1 \leq a < b < c < d \leq n+1, \qquad 1 \leq a < c < b < d \leq n+1,$$
$$1 \leq a < c < d < b \leq n+1, \qquad 1 \leq c < a < b < d \leq n+1,$$
$$1 \leq c < a < d < b \leq n+1, \qquad 1 \leq c < d < a < b \leq n+1.$$

So the total count here is

$$6 \binom{n+1}{4}.$$

Case 2: $|\{a,b,c,d\}| = 3$. Again, there are 6 subcases:

$$1 \le a = c < b < d \le n+1, \qquad 1 \le a = c < d < b \le n+1,$$
$$1 \le c < a = d < b \le n+1, \qquad 1 \le a < b = c < d \le n+1,$$
$$1 \le a < c < b = d \le n+1, \qquad 1 \le c < a < b = d \le n+1.$$

So the total count here is

$$6 \binom{n+1}{3}.$$

Case 3: $|\{a,b,c,d\}| = 2$. Here $1 \le a = c < b = d \le n+1$, so the count for this case is

$$\binom{n+1}{2}.$$

To sum up (!),

$$\begin{aligned}
\sum_{s=1}^{n} s^3 &= 6\binom{n+1}{4} + 6\binom{n+1}{3} + \binom{n+1}{2} \\
&= \left(\sum_{s=1}^{n} s\right)^2 \\
&= \binom{n+1}{2}^2 .
\end{aligned}$$

The reader is invited to find an alternative proof by showing that

$$\binom{n+1}{2}^2 = 6\binom{n+1}{2}\binom{n+2}{4}$$

and that

$$\binom{n+2}{4} = \binom{n+1}{4} + \binom{n+1}{3}.$$

Do either of these formulae generalize?

Yet again, we know

$$s^2 = \binom{s}{2} + \binom{s+1}{2},$$

and you can easily obtain (by counting!) that

$$s^3 = \binom{s}{3} + 4\binom{s+1}{3} + \binom{s+2}{3}.$$

Exercise: obtain coefficients a_{ij} such that

$$s^r = a_{r1}\binom{s}{r} + a_{r2}\binom{s+1}{r} + \ldots + a_{rr}\binom{s+r}{r}\quad 1$$

for the next few values of r, and investigate the properties of the Pascal-like triangle of numbers a_{ij}.

You should get:

... ...

By courtesy of the On-Line Encyclopedia of Integer Sequences (www.research.att.com/~njas/sequences/) I now know that the above numbers are the *Eulerian numbers* and the triangle is known as *Euler's number triangle*. Given a permutation $\rho : i \mapsto \rho_i$ of $\{1, 2, \ldots, n\}$, we write the list of images $\{\rho_1, \rho_2, \ldots, \rho_n\}$; in this list, an *ascent* is a pair of adjacent elements that are in descending order. For example, if $n = 6$ and ρ sends $\{1, 2, 3, 4, 5, 6\}$ to $\{2, 4, 5, 3, 1, 6\}$ respectively, then ρ has two ascents, $\{5, 3\}$ and $\{3, 1\}$.

The Eulerian number $\left\langle {n \atop k} \right\rangle$, where $0 \leq k < n$, is defined to be the number of permutations of $\{1, 2, \ldots, n\}$ having exactly k ascents.

Immediate observations: for $0 \leq k \leq n \quad 1$, $\left\langle {n \atop k} \right\rangle$ is a positive integer, with $\left\langle {n \atop 0} \right\rangle = 1$ and $\left\langle {n \atop n-1} \right\rangle = 1$; and obviously

$$\left\langle {n \atop 0} \right\rangle + \left\langle {n \atop 1} \right\rangle + \ldots + \left\langle {n \quad n \atop n \quad 1} \right\rangle = n!.$$

Next, $\left\langle {n \atop k} \right\rangle = \left\langle {n \atop n-1-k} \right\rangle$, by observing that, if ρ is paired with ρ', where $\rho'_i = n+1 \quad \rho_i$, all i, then the number of ascents in ρ plus the number of ascents in ρ' is $n \quad 1$. Also the relation

$$\left\langle {n \atop k} \right\rangle = (n \quad k) \left\langle {n \quad 1 \atop k \quad 1} \right\rangle + (k+1) \left\langle {n \quad 1 \atop k} \right\rangle$$

comes from observing that if n is inserted into a permutation of $1, 2, \ldots, n \quad 1$ to produce a permutation of $1, 2, \ldots, n$, then it can be inserted in any of n places, and the number of ascents either stays the same or goes up by 1.

Now for s^r. We have that s^r is equal to the number of ways of choosing $n_1, n_2, \ldots, n_r$ with $1 \leq n_i \leq s$, all i. For each such choice, rearrange the n_i in increasing order; this is unambiguous for distinct values, but where two or more n_i have the *same* value, arrange them so that their *subscripts* are in *decreasing* order. Let the new order be $n_{\rho 1}, n_{\rho 2}, \ldots, n_{\rho r}$, which defines a unique permutation ρ.

For example, if $s \quad 5$ and $r = 6$, and $n_1 = 4$, $n_2 = 1$, $n_3 = 4$, $n_4 = 3$, $n_5 = 4$ and $n_6 = 5$, then we have the multiple inequality

$$n_2 < n_4 < n_5 \leq n_3 \leq n_1 < n_6,$$

and ρ sends $1, 2, 3, 4, 5, 6$ to $2, 4, 5, 3, 1, 6$ respectively. If instead we had written $n_1 = 5$ and $n_6 = 6$, we would have obtained the stronger condition

$$n_2 < n_4 < n_5 \leq n_3 < n_1 < n_6.$$

Each choice of $n_1, n_2, \ldots, n_r$ thus gives rise to exactly one permutation ρ. The corresponding multiple inequality involves $1 \le n_{\rho 1}$, $n_{\rho 2}, \ldots, n_{\rho r} \le s$ in that order; if we now insert into this list "$\le$" at each ascent of ρ, and "$<$" elsewhere, then the condition obtained (or maybe a stronger one) is satisfied by our chosen n_i.

The number of ways of solving this multiple inequality, if there are exactly k weak inequalities, is $\binom{s+k}{r}$, and so if we lump together the permutations having the same number of ascents, we obtain

$$s^r = \left\langle {r \atop 0} \right\rangle \binom{s}{r} + \left\langle {r \atop 1} \right\rangle \binom{s+1}{r} + \ldots + \left\langle {r \atop r} \right\rangle \binom{s+r}{r} \binom{1}{1}.$$

This is the equation

$$s^r = a_{r1} \binom{s}{r} + a_{r2} \binom{s+1}{r} + \ldots + a_{rr} \binom{s+r}{r} \binom{1}{1}$$

on page 19, with $a_{rk} = \left\langle {r \atop k-1} \right\rangle$.

Here is a different sort of counting argument. How do we set about finding a basis for a vector space? For example, if we want a basis $\{\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3\}$ for $\mathbb{R}^3$, we choose the first element, $\mathbf{v}_1$, to be any vector in $\mathbb{R}^3$ *except* the zero vector; that is, we avoid the zero-dimensional subspace.

For the second element, $\mathbf{v}_2$, we can choose any vector not linearly dependent on $\mathbf{v}_1$; that is, we avoid the 1-dimensional subspace spanned by $\mathbf{v}_1$.

For the final element, $\mathbf{v}_3$, we can choose any vector not linearly dependent on $\mathbf{v}_1$ and $\mathbf{v}_2$; that is, we avoid the 2-dimensional subspace spanned by $\mathbf{v}_1$ and $\mathbf{v}_2$.

Now let's do this using a different field of scalars: we'll use the field $\mathbb{F}$, which we are going to suppose is *finite*: specifically, suppose $|\mathbb{F}| = q$. (For example, we might choose $\mathbb{F} = \mathbb{Z}_p$, integers modulo a prime number p. In that case we would have $q = p$.)

Over such a field, an r-dimensional space (or subspace of a space) must be isomorphic to $\mathbb{F}^r$, and so will contain q^r elements.

So, to choose a basis $\{\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3\}$ of $\mathbb{F}^3$, we have a choice of $q^3 \quad 1$ vectors for $\mathbf{v}_1$, a choice of $q^3 \quad q$ vectors for $\mathbf{v}_2$, and a choice of $q^3 \quad q^2$ vectors for $\mathbf{v}_3$. Thus the number of different bases is

$$(q^3 \quad 1)(q^3 \quad q)(q^3 \quad q^2).$$

More generally, the number of different bases of $\mathbb{F}^n$ is

$$(q^n - 1)(q^n - q)(q^n - q^2)\dots(q^n - q^{n-1}),$$

since there are q^n vectors altogether, and at the $(r+1)^{\text{th}}$ step we are trying to avoid the q^r vectors in some r-dimensional subspace.

Of course, if we write the elements of a basis in a different order, we get another basis, and this means that the different bases fall into equivalence classes of $n!$ bases each, under the action of permuting the elements. It follows that

$$\frac{(q^n - 1)(q^n - q)(q^n - q^2)\dots(q^n - q^{n-1})}{n!}$$

is an integer, being the number of *unordered* bases of $\mathbb{F}^n$.

Thus we have proved that

$$n! \,\Big|\, (q^n - 1)(q^n - q)(q^n - q^2)\dots(q^n - q^{n-1}).$$

Alternative posh argument: the general linear group $\mathrm{GL}_n(\mathbb{F})$, of all invertible $n \times n$ matrices over $\mathbb{F}$, has order

$$(q^n - 1)(q^n - q)(q^n - q^2)\dots(q^n - q^{n-1}),$$

the successive brackets being the number of choices for successive rows of an invertible matrix. The permutation matrices (obtained by permuting the rows, or columns, of the identity matrix) form a subgroup of this, of order $n!$, and the result follows by Lagrange's theorem.

Now, if $q = |\mathbb{F}|$, where $\mathbb{F}$ is a field, then $\mathbb{F}$ contains a minimal subfield (isomorphic to) $\mathbb{Z}_p$, where p is a prime number, the *characteristic* of $\mathbb{F}$. (p is the additive order of 1 in $\mathbb{F}$, necessarily prime, and $\mathbb{Z}_p$ is the *prime subfield* of $\mathbb{F}$.)

But this means that $\mathbb{F}$ can be regarded as a vector space over $\mathbb{Z}_p$. Since it is finite, it is certainly finite-dimensional; and if its dimension is r then $\mathbb{F} \cong \mathbb{Z}_p^r$ (as $\mathbb{Z}_p$-spaces), and therefore $q = p^r$.

So **the order of a finite field is a prime power**; and in fact for every prime power there is (up to isomorphism) precisely one finite field of that order.

To recap, we have proved that

$$n! \,\Big|\, (q^n - 1)(q^n - q)(q^n - q^2)\dots(q^n - q^{n-1}), \qquad (\star)$$

but we now see that our proof will not work if q is not a prime power.

In fact, $(\star)$ true for every q, though the proof is a bit fiddly. What we shall do is calculate, for *every* prime p, how many times p divides each side of $(\star)$, and compare.

How many times does p divide $n!$?

p divides *once* into each of p, $2p$, $3p$, . . . ;
a *second* time into each of p^2, $2p^2$, $3p^2$, . . . ;
a *third* time into each of p^3, $2p^3$, $3p^3$, . . . ;

and so on. The number of multiples of m that are less than or equal to n is the integer part of n/m, which we denote $[n/m]$. We conclude: $n!$ is divisible by p^r (and not by p^{r+1}), where

$$r = \left[\frac{n}{p}\right] + \left[\frac{n}{p^2}\right] + \left[\frac{n}{p^3}\right] + \ldots .$$

(This makes sense, as all but a finite number of terms on the right are zero.)

Note that

$$r < \frac{n}{p} + \frac{n}{p^2} + \frac{n}{p^3} + \ldots = \frac{n}{p}\left(1 \quad \frac{1}{p}\right)^{-1} = \frac{n}{p \quad 1}.$$

Next, note that

$$\begin{aligned} & (q^n \quad 1)(q^n \quad q)(q^n \quad q^2)\ldots(q^n \quad q^{n-1}) \\ = \; & q^s(q^n \quad 1)(q^{n-1} \quad 1)(q^{n-2} \quad 1)\ldots(q \quad 1) \end{aligned}$$

where

$$s = 0 + 1 + 2 + \ldots + (n \quad 1) = \frac{n(n \quad 1)}{2}.$$

Since p is prime, either $p \mid q$ or else p and q are coprime. In the first case, we need to show that

$$r \leq \frac{n(n \quad 1)}{2}.$$

If $n = p = 2$, then $r = [n/p] = 1$ and also $\frac{n(n-1)}{2} = 1$. On the other hand, if $n > 2$ or $p > 2$ (or both) then

$$2 \leq (n \quad 1)(p \quad 1),$$

whence

$$\frac{n}{p \quad 1} \leq \frac{n(n \quad 1)}{2},$$

and the result follows, since, as we have already shown, $r < \frac{n}{p \quad 1}$.

In the other case, when p and q are coprime, we know that p divides $q^{p-1} \quad 1$, by Fermat's little theorem; and likewise it divides $q^{2(p-1)} \quad 1$, $q^{3(p-1)} \quad 1$, and so on. The number of terms $(q^s \quad 1)$ divisible by p on the RHS of $(\star)$ is thus at least $\left\lceil \frac{n}{p \quad 1} \right\rceil$. But we know $r \leq \frac{n}{p \quad 1}$, and since r is an integer, we must have $r \leq \left\lceil \frac{n}{p \quad 1} \right\rceil$. This finishes the proof: in all cases,

$$n! \,\Big|\, (q^n \quad 1)(q^n \quad q)(q^n \quad q^2) \ldots (q^n \quad q^{n-1}).$$

Suppose we want to combine n elements of some set under a non-associative binary operation. (So $n \quad 2$.) How many ways can we do this, i.e., how many ways can we put in the brackets?

For example, if $n = 3$, the answer is 2, for we can write

$$a(bc) \quad \text{or} \quad (ab)c.$$

Again, if $n = 4$, the answer is 5, for we can write

$$a(b(cd)), \quad a((bc)d), \quad (ab)(cd), \quad (a(bc))d, \quad \text{or} \quad ((ab)c)d.$$

Here is a neat way of getting a formula for the answer, for n symbols. In elementary group theory, the "product" ab, or (ab), is often written using some special symbol such as $\star$, so we might write $a \star b$, to emphasize that this is not (necessarily) ordinary multiplication. We are going to do this, but perversely we shall write it as $\star ab$, not $a \star b$. In this notation, we don't need any brackets! For example, $(ab)c$ is written $\star\star abc$, and $a(bc)$ is written $\star a \star bc$.

To reverse the process, replace each $\star$ by a LH bracket, and you then find there is a unique way of inserting RH brackets to make the answer make sense. For instance,

$$\star\star\, a\; b \star c\; d \to ((ab(cd \to ((ab(cd) \to ((ab)(cd) \to ((ab)(cd)).$$

The symbols a, b, c, ... are just place-holders, so we shall write them *all* as a. A particular way of bracketing a product of n elements can now be represented by a string of $2n$ 1 symbols, n a's and n 1 $\star$'s.

Not every such string is legal, i.e., makes sense: for example, when $n = 2$ the possible strings are

$$\star aa, \quad a \star a, \quad \text{and} \quad aa\star,$$

but only the first of these is legal. However, we make the crucial observation that a suitable (and unique) cyclic permutation of each of the illegal strings will legalize them.

We prove this for general n by induction. We just did the first case, $n = 2$. For larger n, we claim that some cyclic permutation of any given string will contain the sub-string $\star aa$.

Since we have more a's than $\star$'s in our given string, some cyclic permutation of the string (possibly trivial) will bring two or more a's together. However many successive a's occur, they must be preceded by a $\star$ (in the cyclic ordering), so that a cyclic permutation (possibly trivial) will produce the sequence $\star aa$.

We now replace $\star aa$ by a, and this reduces us to the case of $n \quad 1$ a's and $n \quad 2$ $\star$'s, so the result follows by induction.

Here is a worked example with $n = 5$:

$$
\begin{array}{rcccccccccc}
 & a & \star & a & \star & a & a & \star & \star & a & \\
 & a & \star & a & & a & & \star & \star & a & \\
 & a & & a & & & & \star & \star & a & \\
\text{Cycle:} & & & a & & & & \star & \star & a & a \\
 & & & a & & & & \star & & a & \\
\text{Cycle again:} & & & & & & & \star & & a & a \\
 & & & & & & & & & a &
\end{array}
$$

So we *should* have started three from the end:

$$
\begin{array}{rcccccccccc}
 & \star & \star & a & a & & \star & a & \star & a & a \\
\text{which represents} & (& (& a & a) & & (& a & (& a & a))).
\end{array}
$$

We have shown that the number of ways of bracketing a product of n elements is the number of cyclic orderings of $2n \quad 1$ symbols, of which n are the same and the remaining $n \quad 1$ are the same. This is

$$\frac{(2n \quad 2)!}{n!(n \quad 1)!},$$

which we'll denote by $f(n)$. Here are the first few values:

n :	2	3	4	5	6	7	8	9	10
$f(n)$:	1	2	5	14	42	132	429	1430	4862

Rodica Simion

Combinatorial statistics on type-B analogues of noncrossing partitions and restricted permutations

We define type-B analogues of combinatorial statistics previously studied on noncrossing partitions and show that analogous equidistribution and symmetry properties hold in the case of type-B noncrossing partitions. We also identify pattern-avoiding classes of elements in the hyperoctahedral group which parallel known classes of restricted permutations with respect to their relations to noncrossing partitions.

Triangles with Integer Sides and Sharing Barrels

David Singmaster

Barrel sharing problems have been common recreational problems since the Middle Ages. The most common version has three persons wanting to share 7 full, 7 half-full and 7 empty barrels so that each gets the same amount of contents and the same number of barrels. I consider the general problem with *N* of each type of barrel. The number of solutions is seen to be the same as the number of triangles with integer sides and perimeter *N.* These triangles were studied in [**7**] and [**4**] by use of intricate summations. Their work is exposited and extended in [**6**]. Here I give a geometric approach using triangular coordinates which is easier to understand and brings out several further properties, including the connection between the number of incongruent triangles and the partitions into at most three parts. At the end I study more general barrel sharing problems.

Sharing Barrels

Suppose we have *N* barrels of each type: full, half-full and empty. Let $f_i,\ h_i,\ e_i$ be the number of these that the i-th person receives, $i = 1,2,3$. These are clearly nonnegative integers and we shall assume this from now on. Then we have a fair sharing if and only if the following conditions hold.

$$\begin{aligned} &f_i + h_i + e_i = N, \text{ for } i = 1,2,3. \\ &f_i + h_i/2 = N/2, \text{ for } i = 1,2,3. \\ &\sum_i f_i = \sum_i h_i = \sum_i e_i = N. \end{aligned} \tag{1}$$

A little observation and manipulation shows that (1) implies $e_i = f_i$ and $h_i = N - 2f_i$, and hence that (1) is solved by knowing the f_i subject to:

$$\begin{aligned} &\sum_i f_i = N; \\ &f_i \le N/2, \text{for } i = 1,2,3. \end{aligned} \tag{2}$$

Integral Triangles

It is well known and easily seen that three nonnegative lengths x, y, z can form a triangle if and only if the three triangle inequalities hold:

$$x + y \ge z,\ y + z \ge x,\ z + x \ge y. \tag{3}$$

If we set $x + y + z = p$, then (3) is equivalent to:

$$x \le p/2,\ y \le p/2,\ z \le p/2 \tag{4}$$

(The triangle is nondegenerate if and only if the inequalities are all strict.) Hence the solutions for sharing *N* barrels of each type are just the integral lengths that form a triangle of perimeter *N.*

Triangular Coordinates

Consider a triangle of sides x, y, z, and perimeter p. Since $x + y + z = p$, we can view (x, y, z) as a point on the plane $x + y + z = p$, in the triangle cut off by the planes $x = 0$, $y = 0$, $z = 0$. This gives the standard representation of (x, y, z) in triangular coordinates as shown in Figure 1 for the case $p = 5$. (Ignore the broken lines in Figure 1b for the moment.) Letting the spacing between lines be our unit of distance, the point (x, y, z) is located x units from the right edge, y units from the left edge and z units from the bottom edge of the triangle. It is a classic property of the equilateral triangle that the sum of the perpendicular distances from an interior point (x, y, z) to the sides, i.e., $x + y + z$, is a constant, namely the altitude.

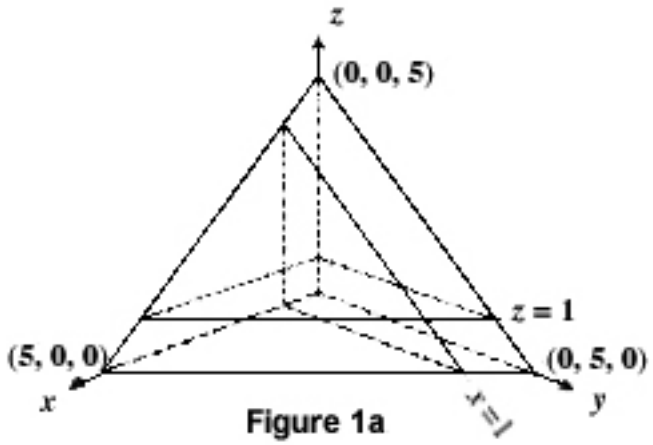

Figure 1a

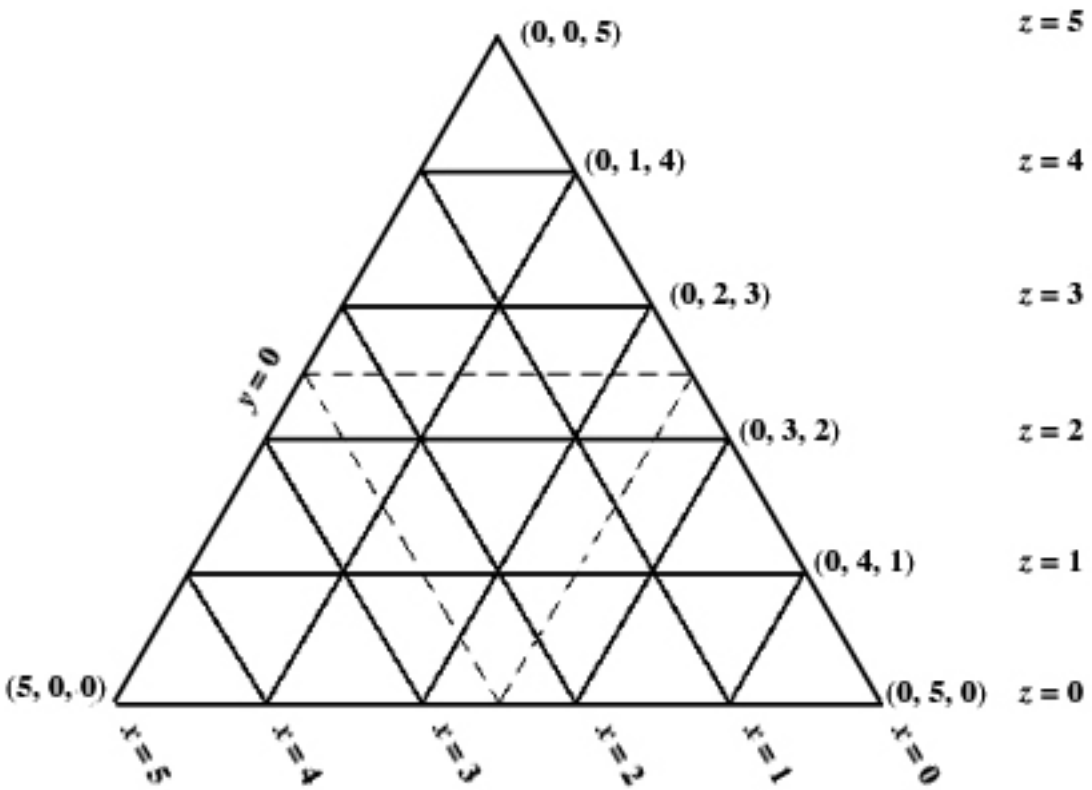

Figure 1b

Triangular coordinates for $p = 5$

If we consider integral values of x, y, z with an integral sum p, we see that these points (x, y, z) form a triangular array having $p + 1$ points along an edge. We denote such an array as **TA**$(p + 1)$. **TA**$(p + 1)$ clearly has $1 + 2 + \cdots + (p + 1) = (p + 1)(p + 2)/2 = T(p + 1)$ points, where $T(p)$ denotes the pth triangular number.

The points along the edges of **TA**$(p + 1)$ correspond to at least one of x, y, z being 0, so the interior points correspond to all lengths being positive. These thus form a triangular array **TA**$(p - 2)$ with $T(p - 2)$ points. Readers will find it useful to draw diagrams as they read on.

The Number of Integral Triangles

In our triangular coordinates, we see that (x, y, z) corresponds to an integral triangle of perimeter p if and only if it is an integer point in **TA**$(p + 1)$ that lies inside the central region cut off by condition (4): $x \le p/2, y \le p/2, z \le p/2,$, as indicated by the broken lines in Figure 1b for $p = 5$.

Let $T_1(p)$ be the number of integral triangles of perimeter p and let $T_2(p)$ be the number that are nondegenerate.

If p is odd (as in Figure 1b), let $p = 2q + 1$. Then the central region cut off by our conditions (4) is a triangle with base on the line $z = q$. This line contains $p + 1 - q = q + 2$ points, but the cut-off region omits the two end points, so our region is a **TA**(q), which contains $T(q)$ points. (Alternatively, take $T(2q + 2) - 3T(q + 1)$ to obtain $T(q)$.) All of these points correspond to nondegenerate triangles, so we have shown that $T_1(p) = T_2(p) = T(q)$. These are precisely the solutions of our barrel sharing problem for p barrels of each type.

If p is even, let $p = 2q$. Then the central region cut off by condition (4) is a triangle whose base is the whole line $z = q$, hence it is a **TA**$(q + 1)$ and we have $T_1(p) = T(q + 1)$. This is the number of solutions of our barrel sharing problem, since we do not restrict ourselves to nondegenerate solutions. But our central region certainly does contain degenerate triangles. We can remove all of these by excluding the lines $z = q, y = q, x = q$. This leaves a central region which is a **TA**$(q - 2)$, so $T_2(p) = T(q - 2)$. (As before, these results can be obtained by subtracting from $T(p + 1)$.)

Note that both $p = 2q - 2$ and $p = 2q + 1$ give the same central region **TA**(q) of integer points corresponding to triangles of perimeter p, while both $p = 2q + 1$ and $p = 2q + 4$ give the same central region **TA**(q) of integer points corresponding to nondegenerate triangles of perimeter p. The latter half of the last sentence is the geometric basis of Theorem 3 in [**7**]. From these observations, we see that $T_1(p) = T_2(p + 3)$. This is also easily seen since adding one to each length gives a one-to-one correspondence between the triangles being counted.

The Number of Incongruent Integral Triangles

In enumerating the solutions of the barrel sharing problems, we do not really care which person gets which share, since each share is fair. If x, y, z is a fair distribution of full barrels, then we consider this as equivalent to y, x, z, etc. I.e.,all six permutations of x, y, z are considered as equivalent solutions.

Viewing x, y, z as sides of a triangle, there are six ways in which it can be congruent to another triangle. That is, one triangle is congruent to another if and only if the sides of one are a permutation of the sides of the other. These correspond to the six permutations of x, y, z and to the six symmetries of our triangular region.

So to count the number of inequivalent solutions of the barrel sharing problem or to count the number of incongruent integral triangles, we need to count the points of our central triangular region that are inequivalent under the symmetries of the triangle.

Let $T_3(p)$ be the number of incongruent integral triangles of perimeter p and let $T_4(p)$ be the number of those that are nondegenerate. Let $N(q)$ be the number of inequivalent points in $\mathbf{TA}(q)$. Figure 2 shows the inequivalent points for $q = 4,5$. Then $T_3(2q-2) = T_3(2q+1) = N(q)$ and $T_4(2q+1) = T_4(2q+4) = N(q)$. Again, there is a shift of three between the general case and the nondegenerate case, i.e., $T_3(p) = T_4(p+3)$.

Figure 2
Inequivalent points for $q = 4, 5$

Theorem 1 $N(q+3) = N(q) + [(q+4)/2]$.

Proof. The array **TA**(q + 3) *is* obtained by bordering **TA**(q). The new inequivalent points are those in the border and they comprise half of a bordering edge. Such an edge has $q + 3$ points and we must count the midpoint when $q + 3$ is odd, giving $[(q+4)/2]$ new inequivalent points.

Corollary 1.1. *The sequence ($N(q)$) is determined by the recurrence in Theorem 1 and the initial conditions:* $N(1) = N(2) = 1, N(3) = 2$. *These values can be extended backward, consistently with the Theorem, to* $N(0) = N(-1) = N(-2) = N(-3) = N(-4) = 0$.

Corollary 1.2. $N(q + 6) = N(q) + q + 5$.

Repeated use of Corollary 1.*2* gives us the following.

Corollary 1.3. *Let* $q - 1 = 6k + r$, *with* $0 < r < 6$.
If $r = 0$, *then* $N(q) = 6T(k) + I = 3k(k + 1) + 1$.
If $r \neq 0$, *then* $N(q) = 6T(k) + r(k + 1) = (3k + r)(k + 1)$.

This corollary holds for $q \geq -4$ and can be extended backward.
Corollaries 1 and *3* contain Theorems 1 and 2 of [**7**], but seem much simpler to me.

Table I
p =2q or 2q + 1

p	q	$T(p)$	$N(p)$	$T_1(p)$	$T_2(p)$	$T_3(p)$	$T_4(p)$

Relation to Partitions

Looking up the sequence $N(q)$ in Sloane's invaluable handbook [**10**], one finds that it is the same as the number of ways that $q - 1$ can be partitioned into at most three parts. To see this, view **TA**(q) as the points (x, y, z) such that $x + y + z = q - 1$. Then taking just the inequivalent points is precisely the same as taking the partitions of $q - 1$ into at most three parts. Let $P_d(n)$ denote the number of partitions of n into at most d parts, so we have $N(n + 1) = P_3(n)$. Then Theorem 1 is a form of the known result that $P_3(n+3) = P_3(n) + P_2(n+3)$. This says that a partition of $n + 3$ either has 3 positive parts, and hence arises from a partition counted by $P_3(n)$ by adding 1 to each part, or has a zero part, and hence arises from a partition counted by $P_2(n+3)$ by adding an extra part of 0. We see also that the number of partitions of $n + 3$ into exactly three parts (i.e., with no zero parts) is just $P_3(n)$.

We have seen that $T_3(2n-2) = N(n)$ and that the latter is equal to $P_3(n-1)$. We can see this another way as follows. $T_3(2n-2)$ counts those triples x_1, x_2, x_3 such that $\sum_i x_i = 2n-2$, with $0 \le x_i \le n-1$. Letting $y_i = n-1-x_i$, we have that $\sum_i y_i = n-1$, with $0 \le y_i \le n-1$. Hence the triple y_1, y_2, y_3 is a partition of $n - 1$.

(The pretty correspondence between x_i and y_i has occurred to several people. It is in my unpublished *1982* paper on integral triangles and was also found by both N. J. Fine and P. Pacitti [**6**, pp. 45-46].)

In the context of barrel sharing, when $N = 2n - 2$, then the x_i are the f_i of Section 1 and so $y_i = N/2 - f_i = h_i/2$. This shows that, for even *N,* the sharing of barrels is determined by sharing the *N/2* pairs of half-full barrels in any way.

Similar arguments apply for the odd case and for the nondegenerate cases. For sharing $N = 2n + 1$ barrels of each type, each person must receive an odd number of half-full barrels. Thus the sharing is determined by giving each person one half-full barrel and then distributing the remaining $(N - 3)/2 = n - 1$ pairs of half-full barrels in any way. Thus $T_3(2n+1) = T_3(2n-2) = P_3(n-1)$.

In [**4**] (and [**6**]), it is shown that the number of partitions of n into three positive parts, i.e., $P_3(n-3)$ is $\{n^2/12\}$, where $\{x\}$ is the nearest integer to x, and hence that $T_4(n) = \{n^2/12\} - \lfloor n/4 \rfloor \cdot \lfloor (n+2/4 \rfloor$. I leave it to the reader to ponder the connection between this and my results: $T_4(2q+1) = T_4(2q+4) = N(q) = P_3(q-1)$, Theorem 1 and its corollaries.

Historical Comments and Other Versions

The earliest examples of barrel sharing problems that I know of are in the ninth century collection attributed to Alcuin [**3**]. His problem 12 is our standard problem with 10 barrels of each type. Problem 51 is a variant - there are four barrels containing 10, 20,30,40 measures of wine and they are to be equally divided among four sons. Alcuin says only that the first two sons should take the 10 and 40 while the other two sons take the 20 and 30. Clearly some shifting of contents is required if each son is to get 25 measures of wine.

In the thirteenth century, Abbot Albert [**1**] gives the problem of dividing nine barrels containing $1,2,\kappa\ ,9$ measures among three persons.

In Bachet [**5**], we find examples where there are different numbers of barrels of the three types and an example where the barrels must be divided among four persons. (Ahrens [**2**] says that some of this material was added by the nineteenth century editor - I haven't seen earlier editions of [**5**] to verify this.)

If we have F full barrels, H half-full barrels and E empty barrels, then condition (1) becomes the following.

$$\begin{gathered} f_i + h_i + e_i = (F+H+E)/3, \text{ for } i = 1,2,3 \\ f_i + h_i/2 = (F + H/2)/3, \text{ for } i = 1,2,3 \\ \sum_i f_i = F, \sum_i h_i = H, \sum_i e_i = E. \end{gathered} \tag{5}$$

When is there an integral solution? The existence of an integral solution imposes certain constraints on *F, H, E,* namely that $2F + H$ and $F + H + E$ must be divisible by 3. These are easily seen to be equivalent to: $F \equiv H \equiv E \pmod 3$. However, we already know that $F = H = E = 1$ has no solution, but looking closer gives the following.

Theorem 2. *There is a fair sharing of F full; H half-full and E empty barrels among three people if and only if*

$$F \equiv H \equiv E (\mathrm{mod}\, 3), \text{ and } H \neq 1$$

Proof. This is a special case of Theorem 3 below.

Initially I thought that the number of solutions of (5) could be found since a solution of (5) would be given by knowing the f_i subject to:

$$\begin{aligned} &\sum_i f_i - F; \\ &f_i \leq (F + H/2)/3, \text{ for } i = 1,2,3. \end{aligned} \tag{6}$$

However, one must also have $0 \leq f_i \leq F$ and $f_i \leq (F + H + E)/3$, and further, that $0 \leq h_i \leq H, h_i \leq (2F + H)/3, h_i \leq (F + H + E)/3$ and $0 \leq e_i \leq E, e_i \leq (F + H + E)/3$. These 11 sets of inequalities give a rather complex set of conditions on the f_i and the same holds if we try to express solutions in terms of the h_i or e_i.

If we wish to share N barrels of each type among k persons, then condition (7) holds.

$$\begin{aligned} f_i + h_i + e_i &= 3N/k, \text{ for } i = 1,2,\ldots,k. \\ 2f_i + h_i &= 3N/k, \text{ for } i = 1,2,\ldots,k. \\ \sum_i f_i &= \sum_i h_i = \sum_i e_i = N. \end{aligned} \tag{7}$$

Again, a solution is determined by knowing the f_i, now subject to simple conditions similar to (2):

$$\begin{aligned} &\sum_i f_i = N; \\ &f_i \leq 3N/2k, \text{ for } i = 1,2,\ldots,k \end{aligned} \tag{8}$$

Geometrically, this leads to simplicial coordinates in k - *1* dimensions, but the problem is no longer the same as finding k integral lengths which form a k-gon of perimeter N, for which the conditions are:

$$\begin{aligned} &\sum_i f_i = N; \\ &f_i \leq N/2, \text{ for } i = 1,2,\ldots,k \end{aligned} \tag{9}$$

It is possible to generalize and extend the previous ideas to find the number of inequivalent solutions of (9), but it is not very illuminating and does not give the simple connection with partitions that occur for $k = 3$. Further, this is not the number of incongruent integral k-gons of perimeter N, since, e.g., this considers a, b, c, d as the same as b, a, c, d and since a quadrilateral with sides a, b, c, d has infinitely many incongruent shapes.

Obviously, one can combine both of Bachet's ideas and try to divide F, H, E among four or k persons. Ozanam [**9**] gives a confused version of this — he seems to start with $F = H = E = 8$, divided among four people, but gives a solution *for* $F = E = 6$, $H = 12$, though he seems to distinguish 6 half-full barrels from 6 half-empty barrels. Some trial and error leads to the following.

Theorem 3. *There is a fair sharing of F full, H half-full and E empty barrels among k people if and only if:*

(a) $F \equiv E \pmod{k}$;
(b) $H \equiv -2F \pmod{k}$;
(c) *if* $(2F + H)/k$ is odd, then $H \geq k$. (10)

Proof. The conditions for a fair sharing are:

(a) $f_i + h_i + e_i = (F + H + E)/k$, for $i = 1, 2, \kappa, k$;
(b) $2f_i + h_i = (2F + H)/k$, for $i = 1, 2, \kappa, k$;
(c) $\sum_i f_i = F, \sum_i h_i = H, \sum_i e_i = E.$ (11)

From (11 -a & b), we get $f_i - e_i = (F - E)/k$ for each i, so that (10-a & b) must hold if there is a solution. If $(2F + H)/k$ is odd, then (11-b) shows that h_i is odd, hence $h_i \geq 1$, for each i. Hence $H \geq k$ and the "only if" part of the theorem is proven.

Suppose that condition (10) holds. Let $F \equiv f \pmod{k}$, with $0 \leq f < k$. If $f = 0$, then we have $F \equiv H \equiv E \equiv 0 \pmod{k}$ and there is an easy solution. Suppose now that $f > 0$. Distribute 1, 0, 1 (i.e., 1 full, 0 half-full and 1 empty barrel) to f people and 0, 2, 0 to the remaining $k - f$ people. This leaves $F - f$, $H - 2(k - f)$, $E - f$ barrels. We have $F - f \equiv E - f \equiv 0$ and $H - 2(k - f) \equiv H + 2f \equiv 0 \pmod{k}$, so these remaining barrels can be easily shared. So we will have a fair sharing, provided only that $H \geq 2(k - f)$, which we rewrite as $(2f + H)/k \geq 2$. Since $f > 0$, we have that $(2f + H)/k > 0$. If $(2f + H)/k = 1$,, then also $(2F + H)/k$ is odd and (10-c) says that $H \geq k$, which gives $(2f + H)/k > 1$.. Hence $(2f + H)/k \geq 2$ and our distribution can indeed be carried out to give a fair sharing.

Note that for $k = 3$, we have $-2 \equiv 1 \pmod{k}$, so that condition (10) simplifies to give the conditions in Theorem 2.

Kraitchik [**8**] has varied the problem still further by having 9 barrels of each of the following five types: full, 3/4 full, 1/2 full, 1/4 full and empty, to be divided among 5 people!

The Sphere Packing Problem

N. J. A. Sloane

Abstract. A brief report on recent work on the sphere-packing problem.

1991 Mathematics Subject Classification: 52C17
Keywords and Phrases: Sphere packings; lattices; quadratic forms; geometry of numbers

1 Introduction

The sphere packing problem has its roots in geometry and number theory (it is part of Hilbert's 18th problem), but is also a fundamental question in information theory. The connection is via the sampling theorem. As Shannon observes in his classic 1948 paper [37] (which ushered in the age of digital communication), if f is a signal of bandwidth W hertz, with almost all its energy concentrated in an interval of T secs, then f is accurately represented by a vector of $2WT$ samples, which may be regarded as the coordinates of a single point in $\mathbb{R}^n$, $n = 2WT$. Nearly equal signals are represented by neighboring points, so to keep the signals distinct, Shannon represents them by n-dimensional 'billiard balls', and is therefore led to ask: what is the best way to pack 'billiard balls' in n dimensions?

This talk will report on a few selected developments that have taken place since the appearance of Rogers' 1964 book on the subject, proceeding upwards in dimension from 2 to 128. The reader is referred to [16] (especially the third edition, which has 800 references covering 1988-1998) for further information, definitions and references. See also the lattice data-base [31].

2 Dimension 2

The best packing in dimension 2 is the familiar 'hexagonal lattice' packing of circles, each touching six others. The centers are the points of the root lattice A_2. The *density* Δ of this packing is the fraction of the plane occupied by the spheres: $\pi/\sqrt{12} = 0.9069\ldots$.

In general we wish to find Δ_n, the highest possible density of a packing of equal nonoverlapping spheres in $\mathbb{R}^n$, or $\Delta_n^{(L)}$, the highest density of any packing in which the centers form a lattice. It is known (Fejes Tóth, 1940) that $\Delta_2 = \Delta_2^{(L)} = \pi/\sqrt{12}$. An n-dimensional lattice Λ of determinant d and minimal nonzero squared length (or *norm*) μ has packing radius $\rho = \sqrt{\mu}/2$ and density $\Delta = V_n\rho^n/\sqrt{\det\Lambda}$, where

$V_n = \pi^{n/2}/(n/2)!$ is the volume of a unit sphere. The *center density* of a packing is $\delta = \Delta/V_n$.

We are also interested in packing points on a sphere, and especially in the 'kissing number problem': find τ_n (resp. $\tau_n^{(L)}$), the maximal number of spheres that can touch an equal sphere in $\mathbb{R}^n$ (resp. in any lattice in $\mathbb{R}^n$). It is trivial that $\tau_2 = \tau_2^{(L)} = 6$.

3 Dimension 3

In spite of much recent work ([20], [21]) Δ_3 is still unknown; nor is Δ_n known in any dimension above 2. It is conjectured that $\Delta_3 = \pi/\sqrt{18} = 0.74048\ldots$, as in the face-centered cubic (f.c.c.) lattice A_3. Muder [28] has shown that $\Delta_3 \le 0.773055\ldots$. It is worth mentioning, however, that there are packings of congruent ellipsoids with density considerably greater than $\pi/\sqrt{18}$ [3].

In two dimensions the hexagonal lattice is (a) the densest lattice packing, (b) the least dense lattice covering, and (c) is geometrically similar to its dual lattice. There is a little-known three-dimensional lattice that is similar to its dual, and, among all lattices with this property, is both the densest packing and the least dense covering. This is the m.c.c. (or *mean-centered cuboidal*) lattice [11] with Gram matrix

$$\frac{1}{2}\begin{bmatrix} 1+\sqrt{2} & 1 & 1 \\ 1 & 1+\sqrt{2} & 1-\sqrt{2} \\ 1 & 1-\sqrt{2} & 1+\sqrt{2} \end{bmatrix} .$$

In a sense this lattice is the geometric mean of the f.c.c. lattice and its dual the body-centered cubic (b.c.c.) lattice. Consider the lattice generated by the vectors $(\pm u, \pm v, 0)$ and $(0, \pm u, \pm v)$ for real numbers u and v. If the ratio u/v is respectively 1, $2^{1/2}$ or $2^{1/4}$ we obtain the f.c.c., b.c.c. and m.c.c. lattices. The m.c.c. lattice also recently arose in a different context, as the lattice corresponding to the period matrix of the hyperelliptic Riemann surface $w^2 = z^8 - 1$

4 Dimensions 4–8

Table 1 summarizes what is presently known about the sphere packing and kissing number problems in dimensions ≤ 24. Entries enclosed inside a solid line are known to be optimal, those inside a dashed line optimal among lattices.

The large box in the 'density' column refers to Blichfeldt's 1935 result that the root lattices $\mathbb{Z} \simeq A_1$, A_2, $A_3 \simeq D_3$, D_4, D_5, E_6, E_7, E_8 achieve $\Delta_n^{(L)}$ for $n \le 8$. It is remarkable that more than 60 years later $\Delta_9^{(L)}$ is still unknown.

The large box in the right-hand column refers to Watson's 1963 result that the kissing numbers of the above lattices, together with that of the laminated lattice Λ_9, achieve $\tau_n^{(L)}$ for $n \le 9$. Odlyzko and I [16, Ch. 13] and independently Levenshtein determined τ_8 and τ_{24}. The packings achieving these two bounds are unique [16, Ch. 14].

Dim.	Densest packing	Highest kissing number	
1	$\mathbb{Z} \simeq \Lambda_1$	2	
2	$A_2 \simeq \Lambda_2$	6	
3	$A_3 \simeq D_3 \simeq \Lambda_3$	12	
4	$D_4 \simeq \Lambda_4$	24	
5	$D_5 \simeq \Lambda_5$	40	
6	$E_6 \simeq \Lambda_6$	72	
7	$E_7 \simeq \Lambda_7$	126	
8	$E_8 \simeq \Lambda_8$	240	
9	Λ_9	272	(306 from P_{9a})
10	Λ_{10} (P_{10c})	336	(500 from P_{10b})
12	K_{12}	756	(840 from P_{12a})
16	$BW_{16} \simeq \Lambda_{16}$	4320	
24	Leech $\simeq \Lambda_{24}$	196560	

Table 1: Densest packings and highest kissing numbers known in low dimensions. (Parenthesized entries are nonlattice arrangements that are better than any known lattice.)

THE 'LOW DIMENSIONAL LATTICES' PROJECT Some years ago Conway and I noticed that there were several places in the literature where the results could be simplified if they were described in terms of lattices rather than quadratic forms. (It seems clearer to say 'the lattice E_8' rather than 'the quadratic form $2x_1^2+2x_2^2+4x_3^2+4x_4^2+20x_5^2+12x_6^2+4x_7^2+2x_8^2+2x_1x_2+2x_2x_3+6x_3x_4+10x_4x_5+6x_5x_6+2x_6x_7+2x_7x_8$'.) This led to a series of papers [7], [10], [13].

Integral lattices of determinant $d = 1$ ('unimodular' lattices) have been classified in dimensions ≤ 25, dimensions 24, 25 being due to Borcherds. In [16, Ch. 15] and [7, (I)] we extended this to $d \leq 25$ for various ranges of dimension.

[7, (II)] is based on the work of Dade, Plesken, Pohst and others, and describes the lattices associated with the maximal irreducible subgroups of $GL(n, \mathbb{Z})$ for $n = 1, \ldots, 9, 11, 13, 17, 19, 23$. Nebe, and Nebe and Plesken (see [29], [32]) have recently completed the enumeration of the maximal finite irreducible subgroups of $GL(n, \mathbb{Q})$ for $n \leq 31$, together with the associated lattices.

[7, (IV)] gives an improved version of the mass formula for lattices, and [7, (V)] studies when an n-dimensional integral lattice can be represented as a sublattice of $\mathbb{Z}^m$ for some $m \geq n$, or failing that, by a sublattice of $s^{-1/2}\mathbb{Z}^m$ for some integer s. [10] describes the Voronoi and Delaunay cells of all the root lattices and their duals, and [7, (VI), (VIII)] discusses how the Voronoi cell of a 3- or 4-dimensional lattice changes as the lattice is continuously varied.

[7, (VII)] determines the 'coordination sequences' of various lattices. Consider E_8, for example, and let $S(k)$ denote the number of lattice points that are k steps from the origin, where a step is a move to an adjacent sphere ($S(1)$ is the kissing

number). Then $\sum_{k=0}^{\infty} S(k)x^k = f(x)/(1-x)^8$, where $f(x) = 1 + 232x + 7228x^2 + \ldots + x^8$. Thus the coordination sequence for E_8 begins 1, 240, 9120, ... For other examples see [39]

Perfect lattices One possible approach to the determination of the densest lattices in dimensions 7 to 9 is via Voronoi's theorem that the density of Λ is a local maximum if and only if Λ is perfect and eutactic [27].

In 1975 Stacey, extending the work of several earlier authors, published a list of 33 perfect lattices in dimension 7. Unfortunately one of the 33 was omitted from her papers and her dissertation. In [7, (III)] we reconstructed the missing lattice and 'beautified' all 33, computing their automorphism groups, etc. In 1991 Jaquet-Chiffelle [22] completed this work by showing that this is indeed the full list of perfect lattices in $\mathbb{R}^7$. This provides another proof that E_7 is the densest lattice in dimension 7.

Martinet, Bergé and their students are presently attempting to classify the eight-dimensional perfect lattices, and it appears that there will be roughly 10000 of them. Whether this approach can be used to determine $\Delta_9^{(L)}$ remains to be seen!

5 Dimension 9. Laminated lattices

There is a simple construction, the 'laminating' or 'greedy' construction, that produces many of the densest lattices in dimensions up to 26. Let Λ_1 denote the even integers in $\mathbb{R}^1$, and define the n-dimensional laminated lattices Λ_n recursively by: consider all lattices of minimal norm 4 that contain some Λ_{n-1} as a sublattice, and select those of greatest density. It had been known since the 1940's that this produces the densest lattices known for $n \leq 10$. In [6] we determined *all* inequivalent laminated lattices for $n \leq 25$, and found the density of Λ_n for $n \leq 48$ (Fig. 1). A key result needed for this was the determination of the covering radius of the Leech lattice and the enumeration of the deep holes in that lattice [16, Ch. 23].

What are all the best sphere packings in low dimensions? In [13] we describe what may be *all* the best packings in dimensions $n \leq 10$, where 'best' means both having the highest density and not permitting any local improvement. In particular, we conjecture that $\Delta_n^{(L)} = \Delta_n$ for $n \leq 9$. For example, it appears that the best five-dimensional sphere packings are parameterized by the 4-colorings of $\mathbb{Z}$. We also find what we believe to be the exact numbers of 'uniform' packings among these, those in which the automorphism group acts transitively. These assertions depend on certain plausible but as yet unproved postulates.

A remarkable property of 9-dimensional packings. We also show in [13] that the laminated lattice Λ_9 has the following astonishing property. Half the spheres can be moved bodily through arbitrarily large distances without overlapping the other half, only touching them at isolated instants, the density remaining

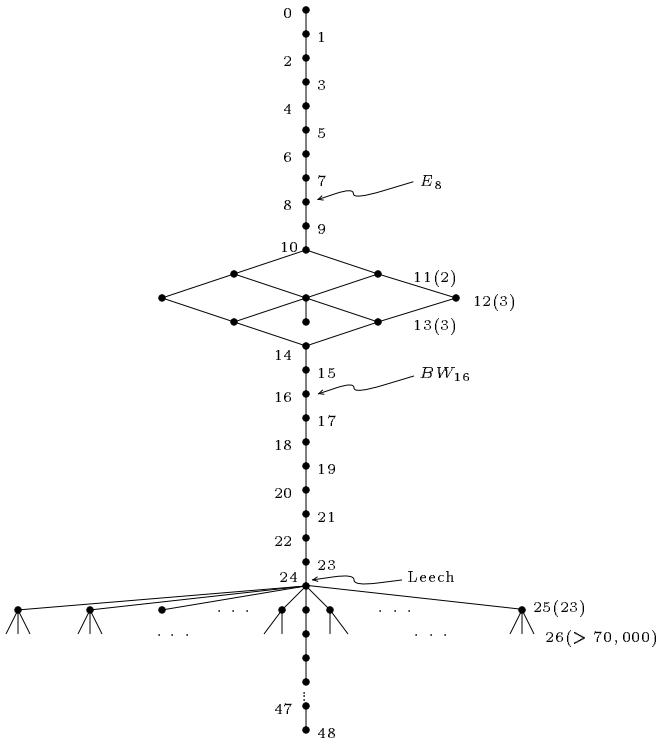

Figure 1: Inclusions among laminated lattices Λ_n.

the same at every instant. A typical packing in this family consists of the points of $D_9^{\theta+} = D_9 \cup D_9 + ((1/2)^8, \theta/2)$, for θ real. D_9^{0+} is Λ_9 and D_9^{1+} is D_9^+, the 9-dimensional diamond structure. All these packings have the same density, which we conjecture is the value of $\Delta_9 = \Delta_9^{(L)}$. Another result in [13] is that there are extraordinarily many 16-dimensional packings that are just as dense as the Barnes-Wall lattice $BW_{16} \simeq \Lambda_{16}$.

6 Dimension 10. Construction A.

In dimension 10 we encounter for the first time a nonlattice packing that is denser than all known lattices. This packing, and the nonlattice packing with the highest known kissing number in dimension 9, are easily obtained from 'Construction A' (cf. [24]). If $\mathcal{C}$ is a binary code of length n, the corresponding packing is $P(\mathcal{C}) = \{x \in \mathbb{Z}^n : x \pmod 2 \in \mathcal{C}\}$.

Consider the vectors $abcde \in (\mathbb{Z}/4\mathbb{Z})^5$ where $b, c, d \in \{+1, -1\}$, $a = c - d$, $e = b + c$, together with all their cyclic shifts, and apply the 'Gray map' $0 \to 00$, $1 \to 01$, $2 \to 11$, $3 \to 10$ to obtain a binary code $\mathcal{C}_{10}$ containing 40 vectors of length 10 and minimal distance 4. This is our description [12] of a code first

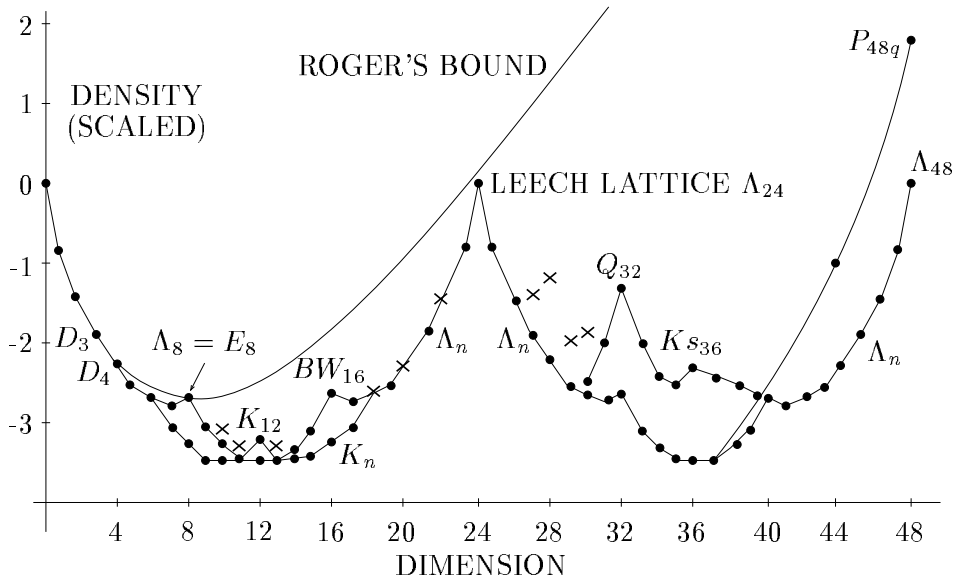

Figure 2: Densest sphere packings known in dimensions $n \leq 48$.

discovered by Best. The code is unique [25]. Then $P(\mathcal{C}_{10}) = P_{10c}$ is the record 10-dimensional packing.

Figure 2 shows the density of the best packings known up to dimension 48, rescaled to make them easier to read. The vertical axis gives $\log_2 \delta + n(24-n)/96$. The figure also shows the upper bounds of Muder (for $n = 3$) and Rogers ($n \geq 4$). Lattice packings are indicated by small circles, nonlattices by crosses (however, the locations of the lattices are only approximate). The figure is dominated by the two arcs of the graph of the laminated lattices Λ_n, which touch the zero ordinate at $n = 0$, 24 (the Leech lattice) and 48. K_{12} is the Coxeter-Todd lattice.

7 Dimensions 18–22

Record nonlattice packings in dimensions 18, 20 and 22 have recently been given in [4], [14], [40]. Vardy's construction [40], 'Construction B^*', also uses binary codes. Let $\mathcal{B}$ and $\mathcal{C}$ be codes of length n such that $c \cdot (\mathbf{1}+b) = 0$ for all $b \in \mathcal{B}$, $c \in \mathcal{C}$, and set $P^*(\mathcal{B}, \mathcal{C}) = \{\mathbf{0}+2b+4x, \mathbf{1}+2c+4y \ : \ b \in \mathcal{B}, c \in \mathcal{C}, x, y \in \mathbb{Z}^n, \sum x_i \text{ even}, \sum y_i \text{ odd}\}$. For example, by taking $\mathcal{B}$ to be the quadratic residue code of length 18 and $\mathcal{C}$ to be its dual, Bierbrauer and Edel [4] obtain a new record packing in $\mathbb{R}^{18}$.

8 Dimension 24. The Leech lattice

The Leech lattice Λ_{24} is a remarkably dense packing in $\mathbb{R}^{24}$ (as can be seen from Fig. 2). Here are four constructions. (i) As a laminated lattice: start in dimension 1 with the lattice $\Lambda_1 = \mathbb{Z}$ and apply the greedy algorithm (see Fig. 1). (ii) Apply

Construction A to the Golay code of length 24 to obtain a lattice L_{24}. Then Λ_{24} is spanned by $(-3/2, 1/2, \ldots, 1/2)$ and $\{x \in L_{24} : \sum x_i \equiv 0 \pmod 4\}$. (iii) Hensel lift the Golay code to an extended cyclic (and self-dual) code over $\mathbb{Z}/4\mathbb{Z}$ and apply 'Construction A mod 4' [5]. (iv) There is a unique unimodular even lattice $\mathrm{II}_{25,1}$ in Lorentzian space $\mathbb{R}^{25,1}$, consisting of the points $(x_0 x_1 \cdots x_{24}|x_{25})$ with all $x_i \in \mathbb{Z}$ or all $x_i \in \mathbb{Z}+1/2$ and satisfying $x_0 + \cdots + x_{24} - x_{25} \in 2\mathbb{Z}$. Let $w = (0\ 1 \cdots 24|70)$, a vector of zero length. Then $(w^\perp$ in $\mathrm{II}_{25,1})/w$ is Λ_{24} [16, Ch. 26].

9 Dimensions 26–31

New packings in these dimensions have been discovered by Bacher, Borcherds, Conway, Vardy, Venkov — see [16] for details.

10 Dimension 32. Modular lattices

An *N-modular* lattice [34] is an integral lattice that is similar to its dual, under a similarity that multiplies norms by N. A unimodular lattice is 1-modular. The interest in this family arises because many of the densest known lattices are N-modular: $\mathbb{Z}$, A_2, D_4, E_8, K_{12}, BW_{16}, Λ_{24}, Q_{32}, P_{48q}, ...

Quebbemann's lattice Q_{32}, for example, is 2-modular, and can be constructed from a Reed-Solomon code of length 8 over $\mathbb{F}_9$ [33], [16, Ch. 8].

Shadow theory. The concept of the shadow of a lattice or code was introduced in [8], [9] (see also [15]) and has proved to be very useful ([9] has stimulated over 50 sequels in the coding literature).

Let Λ be an n-dimensional unimodular lattice. If Λ is even then the *shadow* $S(\Lambda) = \Lambda$, otherwise $S(\Lambda) = (\Lambda_0)^* \setminus \Lambda$, where the subscript 0 denotes even sublattice. The set $2S(\Lambda) = \{2s : s \in S(\Lambda)\}$ is precisely the set of *parity vectors* for Λ, i.e. the vectors $u \in \Lambda$ such that $u \cdot x \equiv x \cdot x \pmod 2$ for all $x \in \Lambda$. Such vectors have been studied by many authors from Braun (1940) onwards, but their application to obtaining bounds on lattices seems to have been overlooked.

If the theta series of Λ is $\Theta_\Lambda(z)$ then [8] the shadow has theta series

$$\left(\frac{e^{\pi i/4}}{\sqrt{z}}\right)^n \Theta_\Lambda\left(1 - \frac{1}{z}\right) \ . \tag{1}$$

One of the most satisfying properties of integral lattices is the classical theorem that (a) if Λ is a unimodular lattice then Θ_Λ belongs to the graded ring $\mathbb{C}[\Theta_\mathbb{Z}, \Theta_{E_8}]$, and (b) if Λ is even then Θ belongs to $\mathbb{C}[\Theta_{E_8}, \Theta_{\Lambda_{24}}]$.

To illustrate the use of the shadow, let us prove there is no 9-dimensional unimodular lattice of minimal norm 2. If so then from (a) $\Theta_\Lambda = -\Theta_\mathbb{Z}/8 + 9\Theta_{E_8}/8 = 1 + 252q^2 + 456q^3 + \cdots$, where $q = e^{\pi i z}$. But then (1) implies $\Theta_{S(\Lambda)} = \frac{9}{4}q^{1/4} + \frac{1913}{4}q^{9/4} + \cdots$, a contradiction since $\Theta_{S(\Lambda)}$ must have integer coefficients.

In [26] we used (a), (b) to show that the minimal norm μ of an n-dimensional odd unimodular lattice satisfies

$$\mu \le \left[\frac{n}{8}\right] + 1 \ , \tag{2}$$

and for an even unimodular lattice

$$\mu \leq 2\left[\frac{n}{24}\right] + 2 \ . \tag{3}$$

In [36] we used shadow theory to strengthen (2) by showing that odd lattices satisfy

$$\mu \leq 2\left[\frac{n}{24}\right] + 2 \ , \tag{4}$$

except that $\mu \leq 3$ when $n = 23$. In view of the similarity between (3) and (4) we propose that a lattice satisfying either bound with equality be called *extremal* (the old definition of this term was based on (2) and (3)).

Quebbemann [35] has generalized (3) to certain families of even N-modular lattices, and analogous bounds for odd N-modular lattices (using an appropriate generalization of the shadow) were given in [36]. One can then define extremal N-modular lattices.

11 Higher dimensions

Space does not permit more than a mention of the following: Kschischang and Pasupathy's lattice Ks_{36} in $\mathbb{R}^{36}$ [23]; the three extremal unimodular lattices P_{48q}, P_{48p}, P_{48n} in $\mathbb{R}^{48}$, the latter being a recent discovery of Nebe [30]; Bachoc's extremal 2-modular lattice in $\mathbb{R}^{48}$ [1]; Nebe's extremal 3-modular lattice in $\mathbb{R}^{64}$ [30]; and Bachoc and Nebe's extremal unimodular lattice in $\mathbb{R}^{80}$ [2].

The existence of the following extremal lattices is an open question: 3-modular in $\mathbb{R}^{36}$ (determinant $d = 3^{18}$, minimal norm $\mu = 8$); 2-modular in $\mathbb{R}^{64}$ ($d = 2^{32}$, $\mu = 10$); unimodular in $\mathbb{R}^{72}$ ($d = 1$, $\mu = 8$).

From dimensions 80 to about 4096 the densest lattices known are the Mordell-Weil lattices discovered by Elkies [19], and Shioda [38]. But we know very little about this range, as evidenced by the recent construction of record kissing numbers in dimensions 32 to 128 [17] from binary codes. In dimension 128, for example, the Mordell-Weil lattice has kissing number 218044170240 [18], whereas in our construction (which admittedly is not a lattice) some spheres touch 8812505372416 others.

It would also be desirable to have better upper bounds, especially in low dimensions (see Fig. 2). The Kabatiansky-Levenshtein bound is asymptotically better than the Rogers' bound, but not until the dimension is above about 40. We know very little about these problems!

In short, many beautiful packings have been discovered, but there are few proofs that any of them are optimal.

Abstract

This paper gives a brief description of the author's database of integer sequences, now over 35 years old, together with a selection of a few of the most interesting sequences in the table. Many unsolved problems are mentioned.

This paper was published (in a somewhat different form) in
Sequences and their Applications (Proceedings of SETA '98),
C. Ding, T. Helleseth and H. Niederreiter (editors), Springer-Verlag, London, 1999, pp. 103-130.

On Single-Deletion-Correcting Codes

N. J. A. Sloane

AT&T Shannon Labs
180 Park Avenue, Florham Park, NJ 07932-0971
njas@research.att.com

Dedicated to Dijen Ray-Chaudhuri on the occasion of his 65th birthday

Jan 10, 2000. Revised Jan 20, 2000, Nov 07 2002.

An earlier version of this paper appeared in
Codes and Designs, Ohio State University, May 2000 (Ray-Chaudhuri Festschrift),
ed. K. T. Arasu and A. Seress, Walter de Gruyter, Berlin, 2002, pp. 273--291.

Abstract

This paper gives a brief survey of binary single-deletion-correcting codes.
The Varshamov-Tenengolts codes appear to be optimal, but many
interesting unsolved problems remain.
The connections with shift-register sequences also
remain somewhat mysterious.

Classification
Primary 94B60; secondary 94A55.

Problems and Remarks:

Each session of the Symposium was concluded by a period devoted to remarks and open problems. These are given in this section, in the chronological order in which they were presented.

1. Remark. For every $n \in \mathbb{N}$ let k_n be an integer with $0 \leq k_n \leq n$. For an arbitrary real number $\lambda_1 \in [0,1[$ define $\lambda_n := \frac{1}{n!}\left(\lambda_1 + \sum_{\nu=1}^{n-1} \nu! k_\nu\right)$ for all $n \in \mathbb{N}$. It is well known that then

$$f\left(\frac{m}{n!}\right) = e^{2\pi m \lambda_n i} \qquad (m \in \mathbb{Z}, n \in \mathbb{N})$$

defines a homomorphism f from $(Q,+)$ into the torus group $(T,\cdot)$ and that conversely every $f \in \mathrm{Hom}(Q,T)$ is obtained in this way.

Theorem. *The function f is continuous ifand only if*

i) *$k_n = 0$ for almost all $n \in \mathbb{N}$, or*

ii) *$k_n = n$ for almost all $n \in \mathbb{N}$.*

If it is continuous f has the form $f(x) = e^{2\pi c x i}$ $(x \in \mathbb{Q})$, where $c \leq 0$ in case i) and $c < 0$ in case ii).

2. Remark and problem. Using a recently developed method for solving certain types of inhomogeneous difference equations, we needed the following system of functional equations for $d : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$:

$$d(x+y,y) = d(x,y); \qquad d(x,y) = d(y,x). \tag{1}$$

L. Paganoni has proved that (1) has solutions different from identically constant functions, which we describe below.

Let H be a Hamel basis for the reals over the rationals $\mathbb{Q}$ and let H_0 be an arbitrary subset of H. Further, Iet $S_0 = V(H_0, \mathbb{Q}, +, \cdot)$ be the subspace of reals generated by H_0. We define the function $h : \mathbb{R} \to \mathbb{R}$ by:

$$h(x) = \begin{cases} 1 & \text{if } x \in S_0 \\ 0 & \text{if } x \notin S_0. \end{cases}$$

Then the function

$$d(x,y) = 1 - h(x)h(y)$$

fulfils conditions (1) and is obviously not constant.

Quite different ís the situation if we suppose continuity of d. Under this assumption all solutions of (1) are identically constant functions. This can be proved in a quite elementary way.

Problem. *Is it true that under the supposition of measurability the general solution of* (1) *is given by a.e. constant functions?*

I. Fenyő

3. Remark. In [1], Lorentz transformations in $\mathbb{R}^n$ (where $n \geq 3$) were characterized in a way for which there is no analogue in $\mathbb{R}^2$. For the indefinite metric

$$d((x_1, y_1), (x_2, y_2)) := (x_1 - x_2)^2 - (y_1 - y_2)^2$$

on $\mathbb{R}^2$, the bijective mappings $T : \mathbb{R}^2 \to \mathbb{R}^2$ with $T(0,0) = (0,0)$ satisfying

$$d((x_1, y_1), (x_2, y_2)) = 0 \qquad \text{iff} \qquad d(T(x_1, y_1), T(x_2, y_2)) = 0$$

are precisely those for which there exist $\delta \in \{-1, +1\}$ and $\phi, \psi : \mathbb{R} \to \mathbb{R}$ bijective such that $\phi(0) = 0 = \psi(0)$ and

$$T(x, y) = \left(\phi\left(\frac{x+y}{2}\right) + \psi\left(\frac{x-y}{2}\right), \delta\phi\left(\frac{x+y}{2}\right) - \delta\psi\left(\frac{x-y}{2}\right) \right)$$

for all $x, y \in \mathbb{R}$ ([2]). For these mappings, the condition

$$T(x_1, y_1) - T(x_2, y_2) = T(x_1, y_2) - T(x_2, y_2) \tag{E}$$

(where $x_1, x_2, y_1, y_2 \in \mathbb{R}$) is necessary and sufficient for T to be additive, while the condition that there exists $\sigma \in \{-1, +1\}$ such that whenever $x_1, x_2, y_1, y_2 \in \mathbb{R}$

$$d((x_1, y_1), (x_2, y_2)) > 0 \qquad \text{implies} \qquad \sigma d(T(x_1, y_1), T(x_2, y_2)) > 0 \tag{M}$$

is necessary and sufficient for T to be continuous.

4. Remark and Problem. Linearizing coordinate transformations for graph papers.

Semi-log and log-log graph papers provide a means of plotting exponential and monomial functions, respectively, as straight lines. This fact yields a convenient method for determining if empirical data are associated with one of these two types of functions.

The author [1] has developed analogous kinds of graph papers for functions satisfying the logistics equation:

$$\dot{x} = x(a - bx)$$

and the Gompertz equation:

$$\dot{x} = x(a - b \ln x).$$

Appropriately normalized solutions of these equations plot as straight lines on the graph papers. (Normalization is necessary since the general solutions of these

equations involve four arbitrary parameters, while straight line are determined by two.)

The form of all four kinds of graph paper was determined from the explicit form of the functions in question, rather than from the form of the corresponding functional or differential equation. (In the case of semi-log and log-log papers, of course, the "corresponding equations" are the appropriate multiplicative forms of Cauchy's equation.) This leads to the following open problem: how can the suitable coordinate spacing for the axes of the linearizing graph paper be obtained directly from the functional or differential equation without finding the explicit form of its solution?

To solve this problem we may require information about f^{-1} (whose functional equation is often obtainable from the functional equation for f, assuming f is invertible), and we may also require some means of numerically approximating the solution of the functional equation directly from the equation (see [2]).

5. Remark. This is a result by C. Wagner (lnstitute of Advanced Studies in the Behavioural Sciences, Stanford, CA. and the University of Tennessee, Knoxville), C. T. Ng, Pl. Kannappan, and myself. Let $f : [0,s]^n \to \mathbb{R}_+ \,(= \{x : x \geq 0\})$ be such that $f(0,0,\dots,0) = 0$ and

$$\sum_{i=1}^{m} x_{ij} = s \qquad (j = 1,2,\dots,n) \qquad \text{implies} \qquad \sum_{i=1}^{m} f(x_{i1}, x_{i2}, \dots, x_{in}) = s$$

(where $m > 2, n, s$ fixed). Then there exist $w_j \geq 0\,(j = 1,2,\dots,n)$, $\sum_{j=1}^{n} w_j = 1$ such that

$$f(x_1, x_2, \dots, x_n) = \sum_{j=1}^{n} w_j x_j \qquad \text{for all} \quad (x_1, x_2, \dots, x_n) \in [0,s]^n.$$

One of the possible interpretations is the following. A (say, grant) amount s should be allocated to m applicants. The decision maker (committee chairman) asks n advisors (committee members). The j-th advisor recommends that the i-th applicant obtain the amount x_{ij}. The decision maker allocates $f(x_{i1}, x_{i2}, \dots, x_{in})$ to the i-th applicant. The only conditions are that each advisor and also the decision maker allocate non-negative amounts to each applicant and the entire amount s is allocated by them to all appticants taken together, and the decision maker has to respect unanimous rejection (0 allocation) by all advisors. (Notice that the result compels the decision maker to respect also all other unanimous advice. The w_j in the result will be the "weight" of the j-th advisor and the final allocation will be a weighted arithmetic mean of the individual recommendations.) This is a characterization of the weighted arithmetic mean.

The cases $m \leq 2$ are also completely settled (then there are other solutions too).

The above results are stronger (the conditions weaker) than those reported at the 1979 meeting.

J. Aczél

6. Remark. Concerning Professor Fenyő's remark (Remark 2, these Proceedings) about non-constant and regular solutions $d : \mathbb{R}^2 \to \mathbb{R}^2$ of the system

$$d(x+y,y) = d(x,y), \qquad d(x,y) = d(y,x).$$

Consider Paganoni's solution $d := 1 - \chi_{V\times V}$ (with χ denoting characteristic functian), where V is an arbitrary subgroup of the additive group of all reals. If V is countable, then d is Borel measurable and locally integrable.

K. Baron

7. Remark. M. Laczkovich (University of Budapest) has solved Kemperman's problem (Aequationes Math. **4** (1970), 248–249) by proving that every solution of

$$2f(x) \le f(x+h) + f(x+2h)$$

(for all real x and all positive h) is nondcreasing.

J. Aczél

8. Problem. In connection with the construction of a collective preference from any n given individual preferences, the following problem arises:

Let $n, m \in \mathbb{N}; x^1, x^2, \dots, x^n \in S \subseteq \mathbb{R}^m$. Find all (continuous or even differentiable) vector-valued solutions $f^n : S^n \to S$ of the system of functional equations:

(1) $f^n(x^{\pi(1)}, \dots, x^{\pi(n)}) = f^n(x^1, \dots, x^n)$, for all permutations π and for all $x^1, \dots, x^n \in S$,

(2) $f^n(x, x, \dots, x) = x$ for all $x \in S$.

(3) $f^n(f^k(x^1, \dots, x^k), \dots, f^k(x^1, \dots, x^k), x^{k+1}, \dots, x^n) = f^n(x^1, \dots, x^k, x^{k+1}, \dots, x^n)$ for all natural numbers $k \le n$ and for all $x^1, \dots, x^n \in S$,

where additionally the i-th component of f^n (i.e. f^n_i) is a strictly monotonically increasing function of the i-th components of the vectors $x^1, \dots, x^n$ (i.e. of the variables $x^1_i, x^2_i, \dots, x^n_i$).

Remark. It is known that the functions f^n defined by

$$f^n_i(x^1, \dots, x^n) = g^{-1}\left(\frac{1}{n}\sum_{l=1}^{n} g(x^l_i)\right) \qquad (i = 1, 2, \dots, m)$$

with an arbitrary strictly monotonic (continuous or even differentiable) function g, defined on a proper subset $G \subset \mathbb{R}$, are solutions for any $n \in \mathbb{N}$.

F. Stehling

9. Remark. Let us consider the following functional equation:

$$f(x+y)[f(x) + f(y) - 1] = f(x)f(y) \qquad x, y \in S \tag{1}$$

where S is a given subset of the reals. I. Fenyő and L. Paganoni have proved the following theorem (see C. R. Math. Rep. Acad. Sci. Canada **2** (1980), 113–117).

Theorem 1. *The most general solution $f : S \to \mathbb{R}(S \subset \mathbb{R})$ of equation (1) is the following:*

$$f(x) = \begin{cases} 0 & \text{if } x \in S_0 \\ 1 & \text{if } x \notin S_1 \\ \frac{1}{1-g(x)} & \text{if } x \in S_2 \end{cases} \tag{2}$$

where S_0, S_1, S_2 are disjoint half-groupoids (some of which may be empty), whose union is the set S and which have the following properties:

$$S \cap (S_0 + S_2) \subset S_0, \tag{3a}$$

$$S \cap (S_1 + S_2) \subset S_1, \tag{3b}$$

and g is an arbitrary solution of the Cauchy functional equation which does not take the values 0 and 1.

Corollary. *If the domain of f contains the origin, then the most general solution of (1) is the characteristic function of a half-groupoid contained in S.*

The following problem suggested by J. Aczél arises: given an arbitrary subset S of the set of nonzero real numbers, is it in any case possible to cut it into three disjoint nonempty halfgroupoids so that conditions (3a) and (3b) are fulfilled? A partial answer to this problem is contained in the following theorem.

Theorem 2. *Let S be a subset of the nonzero reals; and let $V(S)$ be the rational subspace of $\mathbb{R}$ generated by S. If $\dim V(S) > 2$, then it is possible to find three disjoint nonempty halfgroupoids S_i $(i = 0, 1, 2)$ for which the conditions (3a) and (3b) are fulfilled.*

In a more general way we can state that the answer to the question above is surely affirmative if a maximal hyperplane H exists with $S \cap H \neq \emptyset$ and which divides all other elements of S into two disjoint parts.

I. Fenyő

10. Remark (concerning the talk of Professor J. Baker). Recently P. Cholewa (Silesian University, Katowice) has proved a generalization of Professor Baker's first result on a problem of E. Lukacs concerning the stability of the functional equation

$$f(x + y) = f(x)f(y).$$

In particular, if a nonempty set S, a positive real number δ, and a metric space (X, ρ) are given, then any function $f : S \to X$ fulfilling the condition

$$\rho(f(G(x, y)), H(f(x), f(y))) < \delta, \qquad x, y \in S,$$

has to be either (metrically) bounded or to satisfy the funetional equation

$$f(G(x, y)) = H(f(x), f(y)), \qquad x, y \in S,$$

where $G : S \times S \to S$ and $H : X \times X \to X$ are given functions subjected to some rather natural and fairly general assumptions.

R. Ger

11. Problem. Let $f : \mathbb{R}^n \to \mathbb{R}$ be a function with the properties that $f(0) = \frac{\partial f}{\partial x_i}(0) = 0$ $(i = 1, 2, \ldots, n)$, and that the rank of the matrix $\left|\frac{\partial^2 f}{\partial x_i \partial x_j}\right|$ is r at each point of $\mathbb{R}^n$.

Does there exist a linear coordinate transformation such that f can be expressed as a function of just r variables?

The answer is known to be affirmative in the case $r = 2$ and is negative on certain proper subsets of $\mathbb{R}^n$.

M. A. McKiernan

12. Remark. The functional equation

$$f(xy) + f(x + y) = f(xy + x) + f(y) \tag{1}$$

where $f : R \to G$, and R is a ring, G is a group, was introduced at the 17^{th} International Symposium on Functional Equations at Oberwolfach. At the present Symposium, R. Ger has announced some results on this equation, so it may be of interest to show (below) that if f satisfies (1), then the function taking x to $f(-x)$ satisfies Hosszú's functional equation:

$$f(xy) + f(x + y - xy) = f(x) + f(y). \tag{H}$$

So assume f satisfies (1). Let $y = -1$ in (1). Then we deduce

$$f(x - 1) = f(0) + f(-1) - f(-x). \tag{2}$$

Again in (1), let $x = u + 1$, $v = y - 1$, and use (2) to show

$$-f(u - v - uv) + f(u + v) = f(uv + v) - f(-v). \tag{3}$$

A final use of (1), with $x = v, y = u$ allows one to replace $f(uv + v)$ in (3) by $f(uv) + f(u + v) - f(u)$; and so (3) becomes:

$$f(uv) + f(u - v - uv) = f(u) + f(-v). \tag{4}$$

Replacing u by $-u$ we deduce

$$f(-(u + v - uv)) + f(-uv) = f(-u) + f(-v). \tag{5}$$

Hence, if we let $g(x) := f(-x)$, then g satisfies Hosszú's functional equation (H).

If R is a division ring with at least 5 elements, then solutions of Hosszú's equation satisfy

$$f(x + v) + f(0) = f(x) + f(y). \tag{6}$$

For such division rings R, therefore, the solutions of (1) are precisely tlte solutions of (6).

T. Davison

13. Remark. The characterization of the inner product in $\mathbb{R}^3$ given by J. Aczél ([1], p. 310, Satz l; [2], pp. 27–28) may be generalized as follows:

If $(X : \langle \cdot, \cdot \rangle)$ is a reat inner product space, let $\mathrm{SO}(X, 2)$ denote the set of all linear isometries $T : X \to X$ with a 2-dimensional invariant subspace M such that the restriction $T_M : M \to M$ of T is an orientation-preserving rotation of M (i.e. $T_M \in \mathrm{SO}(M : \langle \cdot, \cdot \rangle)$) and $Tx = x$ for every x in the orthogonal complement of M. Suppose that the mapping $g : X \times X \to \mathbb{R}$ has the properties

1) $g(Tx, Ty) = g(x, y)$ for all $x, y \in X$ and every $T \in \mathrm{SO}(X, 2)$.

2) $g(x_1 + x_2, y) = g(x_1, y) + g(x_2, y)$ for all $x_1, x_2, y \in X$,

3) $g(x, \lambda y) = \lambda g(x, y) = g(\lambda x, y)$ for all $x, y \in X$ and all $\lambda \in \mathbb{R}$.

Then the following statements can be proved:

a) If $\dim X \neq 2$, then $\langle x, y \rangle = 0$ implies $g(x, y) = 0$.

b) If $e, e' \in X$, with $\|e\| = \|e'\| = 1$, then $g(e, e) = g(e', e')$.

c) g is additive in its second variable, i.e. g is bilinear.

d) If $\dim X \neq 2$, g is symmetric.

e) If $\dim X \neq 2$, there exists $\alpha \in \mathbb{R}$ such that $g(x, y) = \alpha \langle x, y \rangle$ for all $x, y \in X$.

f) For the case $\dim X = 2$, the conclusions in a), d), and e) do not hold.

14. Remark. Some results of D. Zupnik on congruences and endomorphisms.

Let S be a set and n a positive integer. An n-ary operation on S is a function G from S^n into S. An equivalence relation – on S is a congruence on S with respect to G if $x_i \sim y_i$ for $i = 1, 2, \ldots, n$ implies $G(x_1, \ldots, x_n) = G(y_1, \ldots, y_n)$. At the I976 Symposium at Lecce and Castro Marina, congruences were characterized in terms of functional equations (see Aequationes Math. **15** (1977), p. 284). Recently, D. Zupnik has developed this characterization and used it to obtain related results. Among these are the ones which follow.

Definition 1. A function f is an n-congruence on an n-ary operation G on S if $\operatorname{Dom} f = S$, f is idempotent, and

$$f(G(x_1, \ldots, x_n)) = f(G(f(x_1), \ldots, f(x_n))) \tag{1}$$

for all $x_1, \ldots, x_n$ in S.

Theorem 1. *An equivalence relation – on S is a congruence on S with respect to the n-ary operation G on S if and only if there exists an n-congruence f on G such that $x - y$ iff $f(x) = f(y)$.*

An n-congruence f on G is always an endomorphism of the n-ary operation $f \circ G$, but need not be an endomorphism of G itself.

Theorem 2. *Let f be an n-congruence on the n-ary operation G. Let G_0 be the restriction of G to $(\operatorname{Ran} f)^n$. Then f is an endomorphism of G if and only if G_0 is an n-ary operation on $\operatorname{Ran} f$, or equivalently, if and only if*

$$f(G(x_1, \ldots, x_n)) = G(x_1, \ldots, x_n) \tag{2}$$

for all $x_1, \ldots, x_n$ in $\operatorname{Ran} f$.

Definition 2. An n-congruence f on an n-ary operation G admits an endomorphism of G if there exists an invertible function f_1 such that $\operatorname{Dom} f_1 = \operatorname{Ran} f$ and $f_1 \circ f$ is an endomorphism of G.

It is easily seen that if f is an endomorphism of G; then f admits an endomorphism of G. Furthermore, we have:

Theorem 3. *Let f be an n-congruence on an n-ary operation G. Then f admits an endomorphism of G if and only if there exists a subset S_1 of S such that*

a) $\operatorname{Card} S_1 = \operatorname{Card}(\operatorname{Ran} f)$,

b) *if G_1 denotes the restricrion of G to S_1^n, then G_1 is an n-ary operation on S_1,*

c) *the n-ary operation G_1 is isomorphic to the n-ary operation $f_2 \circ G_0$, where G_0 is as in the preceding theorem.*

A. Sklar

15. Remark. G. Fredricks (Texas Tech University) has proved the following result.

Let U be open in $\mathbb{R}^k$, A a smooth map of U into the gróup of symmetric $n \times n$ matrices, p and q nonnegative integers with $p + q \leq n$. Then there exists a smooth map $G : U \to GL(n)$ satisfying

$$G(\overline{x})A(\overline{x})G^T(\overline{x}) = \operatorname{diag}(1, \ldots, 1, -1, \ldots, -1, 0, \ldots, 0)$$

for all $\overline{x} \in U$ (with p 1's and q -1's in the diagonal matrix on the right) if A has p positive and q negative eigenvalúes at each $\overline{x} \in U$ and U is smoothly contractible.

B. Ebanks

16. Remark. The solution of a problem of Alsina, and its generalization.

Let F and G be functions from the unit square onto the unit interval that are associative, continuous, and non-decreasing in each place, and having no interior idempotents.

ln problem **P193** (Aequationes Math. **20** (1980), p. 308), C. Alsina proposed the equation

$$F(x, y) \cdot G(x, y) = xy.$$

Its only solutions consist of the one-parameter family

$$F_\alpha(x, y) = (x^{-\alpha} + y^{-\alpha} - 1)^{-\frac{1}{\alpha}}, \quad G_\alpha(x, y) = (x^\alpha + y^\alpha - x^\alpha y^\alpha)^{\frac{1}{\alpha}}, \qquad 0 < \alpha < \infty.$$

(Note the limiting case $F_\infty = \min$. $G_\infty = \max$.)

The related equation

$$F(x, y) + G(x, y) = x + y$$

is solved in my paper (Aequationes Math. **19** (1979),194–226). Extensions of this result to functions defined on unbounded intervals yield the solutions of the rnore general equation

$$H(F(x, y), G(x, y)) = H(x, y)$$

for any H which can be written $H(x, y) = k(h(x) + h(y))$, with continuous and monotonic h and k. In particular. when $h(0) = -\infty$ and $h(1) = 0$, the functions

$f_\alpha(x) = 1 - \exp[-\alpha h(x)]$, $0 < \alpha < \infty$, generate the family of solutions F_α.

M. J. Frank

17. Problems Let

$$D = \{(x, y) : x, y \in [0, 1[, x + y \leq 1\}$$

and let

$$D_0 = \{(x, y) : x, y, x + y \in]0, 1[\}$$

be its interior.

(1) Determine the general real-valued solutions f of

$$f(x, u) + (1 - x)f\left(\frac{y}{1 - x}, \frac{v}{1 - u}\right) = f(y, v) + (1 - y)f\left(\frac{x}{1 - y}, \frac{u}{1 - v}\right) \qquad (1)$$

on $D_0 \times D_0$.

(2) Determine the general (real-valued) solutions F, G, H, K (all four functions unknown) of

$$F(x) + (1 - x)^\alpha G\left(\frac{y}{1 - x}\right) = H(y) + (1 - y)^\alpha K\left(\frac{x}{1 - y}\right) \qquad (2)$$

on D_0, (α a fixed constant).

The second problem may lead to the solution of the first, but there may be a simpler way. Equation (1) has been solved on $D \times D$ and on $D \times D_0$ (the solutions are essentially diffierent): equation (2) has been solved on D.

(3) Determine the general solutions of (2) on D_0 when t^α is replaced on both sides by $m(t)$, $m :]0, 1[\to \mathbb{R}$ being an arbitrary multiplicative function ($m(tu) = m(t)m(u)$, $t, u \in]0, 1[$). Again, similar equations (but not this one) have been solved by Kannappan and Ng.

The general solution, on $D_0 \times D_0$, of equations similar to (1), but with $(1 - x)$ replaced by $(1 - x)^\alpha(1 - u)^\beta$ [and $(1 - y)$ by $(1 - y)^\alpha(1 - v)^\beta$] ($\alpha, \beta$ arbitrary constants but $(\alpha, \beta) \neq (0, 1), (1, 0)$), and of similar n-dimensional equations, have been determined by Ng.

J. Aczél

18. Remark. A relationship of Catalan Numbers to Pascal's Triangle. We will call the identity

$$\binom{n+1}{r} = \sum_{k=0}^{r} \binom{n-r+k}{k}$$

the "stocking theorem" for Pascal's triangle, for the reason suggested by the figure below.

Figure 1:

(where in this case the overlay pattern illustrates the special.case $10 = 1 \cdot 6 + 1 \cdot 3 + 1 \cdot 1$ of the "stocking theorem").

The author has obtained generalizations of Pascal's triangle through the use of functional equations, and for each of these, there is a stocking theorem, analogous to the one above, which expresses each element of the generalized triangle as a certain linear combination of "higher" elements of the triangle. The coefficients in this linear combination are the first r elements of the stocking sequence associated with the triangle. (In the case of Pascal's triangle, the stocking sequence is simply $1, 1, 1, \ldots$.)

The generalized Pascal triangle T01 gives the number of ways of choosing n objects r at a time where, if an element is used at all, it must be used twice. The recurrence relation for this triangle is

$$C(n+1, r) = C(n, r) + C(n, r-2),$$

and the associated stocking sequence is

$$1, 0, 1, 0, 2, 0, 5, 0, 14, 0, 42, 0, 132, 0, \ldots .$$

which turns out to be the sequence of Catalan numbers

$$T_i = \frac{1}{i+1}\binom{2i}{i},$$

with zeros interspersed (see [1]).

For T01, it can be easily shown that $C(n, r) = 0$ for odd r. If we remove these zero columns from T01, we get Pascal's triangle T1, which means that the stocking theorem for T01 can be reinterpreted as the following statement relating the binomial coefftcients to the Catalan numbers T_i (defined above):

$$\binom{n+1}{r} = \sum_{i=0}^{r-1} T_i \binom{n-2i}{r-i-1},$$

where, for negative m, $\binom{m}{k}$ is the (unique) number determined by the Pascal recurrence relation

$$\binom{m+1}{k} = \binom{m}{k} + \binom{m}{k-1}$$

and by $\binom{m}{0} = 0$ for all integers m.

19. Problem. Assume that

$$\sum_{i=1}^{k} \mu_i f(x + \phi_i(t)) = f(x) \tag{1}$$

for all $x \in \mathbb{R}^n, t \in \Delta \subset \mathbb{R}$: where $\sum_{i=i}^{k} \mu_i = 1, \mu_i > 0$ for $i = 1, \ldots, k$, and there exists an $\alpha \in \Delta$ such that $\phi_i(\alpha) = 0$ for $i = 1, \ldots, k$.

If the set of $\phi_i'(\alpha)$ (for $i = 1, \ldots, k$) spans $\mathbb{R}^N$, then every locally integrable solution f of (1) is a C^∞ function (see [1]).

Question. *Are all the locally integrable solutions of (1) C^∞ functions if $\{(\phi_i'(\alpha) : i = 1, \ldots, k\}$ does not span $\mathbb{R}^N$, but $\{(\phi_i''(\alpha) : i = 1, \ldots, k\}$ does?*

References

H. Światak

20. Problem. Find all functions $F :]0, \infty[\to \mathbb{R}$ satisfying:

$$F(xy) = F(x)F(y) \qquad \text{and} \qquad F(x + y) \leq F(x) + F(y)$$

for all $x > 0$ and $v > 0$.

This problem arises in the calculation of entropy functions of degree $\alpha < 1$. Discontinuous solutions of the system are known to exist.

Gy. Maksa

21. Remark. It has been pointed out by V. I. Arnold and A. A. Kirilov that the function $\mathrm{Min}(x, y)$ admits no representation of the form

$$\mathrm{Min}(x, y) = f(g(x) + g(y)),$$

where f and g are continuous. A stronger result is easily established:

Theorem. *Let $A = [a, b]$ be a subinterval of the extended real line, and let $T : A \times A \to A$ define a semigroup on A such that for some $a < \overline{x} < b$,*

$$T(a, a) = a, \qquad T(\overline{x}, \overline{x}) = \overline{x}, \qquad T(b, b) = b.$$

Then there are no continuous functions f, g such that T can be represented in the form $T(x, y) = f(g(x) + g(y))$.

G. Krause

22. Remark. The following problem of Colin Rogers arises in gas dynamics in connection with the theory of Bäcklund transformations. Given real constants α, a, b, c, d, find smooth solutions $\phi :]0, \infty[\to \mathbb{R}$ such that

$$\phi(x) = \alpha(x + c)^2 \left[\phi\left(a + \frac{b}{x + c}\right) + d\right], \qquad x > 0. \tag{1}$$

We assume a, b, and c are such that $a + \frac{b}{x+c}$ is defined and positive whenever $x > 0$. In the homogeneous case ($d = 0$) the real analytic solutions of (1) can be found explicitly (they are rational functions in nontrivial cases) with the aid of the following theorem.

Theorem 1. *Let D be an open connected subset of $\mathbb{C}$ (the complex numbers) and let $g : D \to D$ be analytic and have a fixed point z_0 such thnt $0 < |g'(z_0)| < 1$ and $g^k(z) \longrightarrow z_0$ as $k \longrightarrow +\infty$ for every $z \in D$. Also let $f : D \to \mathbb{C}$ be anatytic with $f(z_0) = 1$, let $\lambda \in \mathbb{C}$ and suppose that $\phi : D \to \mathbb{C}$ is analytic and such that*

$$\lambda\phi(z) = f(z)\phi(g(z)), \qquad z \in D. \tag{2}$$

Then there exist analytic functions $F, G : D \to \mathbb{C}$ such that

(i) *if $\lambda \neq (g'(z_0))^k$ for all $k = 0, 1, 2, \ldots$, then $\phi \equiv 0$ and*

(ii) *if $\lambda = (g'(z_0))^k$ for some $k = 0, 1, 2, \ldots$ then there exists $\gamma \in \mathbb{C}$such that $\phi(z) = \gamma F(z)[G(z)(z - z_0)]^k$, $z \in D$.*

If we let $\Phi_k(z) = F(z)[G(z)(z - z_0)]^k$, for $z \in D, k = 0, 1, 2, \ldots$, then we can prove:

Theorem 2. *Given $h : D \to \mathbb{R}$ analytic, there exist $\delta > 0$ and a complex sequence $\{c_k\}_{k=0}^{+\infty}$ such that*

$$h(z) = \sum_{k=0}^{+\infty} c_k \Phi_k(z)$$

for $|z - z_0| < \delta$. Moreover the convergence is almost uniform on $\{z \in D : |z - z_0| < \delta\}$.

Using Theorem 2, one can determine the real analytic solutions of (1) in the nonhomogeneous case.

J. A. Baker

23. Remark. A function f, holomorphic in $D = \{z : |z| < 1\}$, is said to be annular in case there is a sequence $\{J_n\} \subset D$ of Jordan curves about 0 such that

$$\lim_{n\to\infty} \min\{|f(z)| : z \in J_n\} = \infty.$$

One can base a prooi for the annuiarim of

$$f(z) = \sum_{n=0}^{\infty} a^{cn} z^{a^n} \tag{1}$$

(where $c > 0, a = a(c)$, a sufiiciently large integer), on known methods and the fact that f satisfies the functional equation

$$f(z) - a^c f(az) = z.$$

Hardy and Littlewood in 1916 related (1) via a functinonal equation to

$$F(\zeta) = \sum_{n=1}^{\infty} n^{\delta -} e^{\beta n \log n} \zeta^n \tag{2}$$

($\delta > 0, \beta > 0$ certain constants), and thereby one can show that (2) is also annular. Fatou showed that for certain rational functions, for example

$$R(z) = \frac{z(z-s)}{1-sz}$$

c complex. $0 < |s| < 1$, the nontrivial analytic solutions of the Schröder equation

$$f(R(z)) = -sf(z)$$

are annular.

I would appreciate hearing of othter connections between functional equations and annular functions.

F. Carroll

24. Problem. Let $(F, +, \cdot)$ be a system with the following properties:

I. $(F, +)$ is a toop (with identity 0).

II. $(F - \{0\}, \cdot)$ is a group.

III. $(a + b) \cdot c = a \cdot c + b \cdot c$ and $c \cdot 0 = 0$, for all $a, b, c \in F$.

IV. (Limited associativity) $(x + a) + b$ is equal to $x + (a + b)$ if $b + a = 0$, and is equal to $x(b + a)^{-1}(a + b) + (a + b)$ otherwíse.

Question. *Do the conditions I-IV imply that $(F, +)$ is an abelian group?*

The answer is known to be affirmative in case F has finite cardinality, or under some other additional assumptions, such as $a(1+1) = a+a$; or $1+1+1 = 0$.

W. Leissner

25. Remark. Solution of Problem 17 (2) (of these Proceedings).

In answer to a problem of J. Aczél, we have proved the following:

Theorem. *Ler $\alpha \in \mathbb{R}$ be fixed. $D_0 = \{(x, y) \in \mathbb{R}^2 : x, y, x + y \in]0, 1[\}$. The functions $F, G, H, K :]0, 1[\to \mathbb{R}$ satisfy*

$$F(x) + (1-x)^\alpha G\left(\frac{y}{1-x}\right) = H(y) + (1-y)^\alpha K\left(\frac{x}{1-y}\right)$$

for all $(x, y) \in D_0$ if and only if, for all $x \in]0, 1[$,

$$F(x) = \begin{cases} \phi(x) + \phi(1-x) + a_1 x + a_2(1-x) + a_3 & \text{if } \alpha = 1 \\ l_1(1-x) + l_2(x) + a_1 & \text{if } \alpha = 0 \\ d(x) + a_1 x^2 + a_2(1-x)^2 + a_3 & \text{if } \alpha = 2 \\ a_1 x^\alpha + a_2(1-x)^\alpha + a_3 & \text{otherwise} \end{cases}$$

$$G(x) = \begin{cases} \phi(x) + \phi(1-x) + a_1' x \\ \quad +(a_1 - b_1 + a_3 - b_3 - b_1' + a_1' + b_2')(1-x) \\ \quad +b_1 - a_2 - a_3 + b_3 - a_1' & \text{if } \alpha = 1 \\ l_1(1-x) + l_3(x) - l_3(1-x) + b_1 - a_1 + b_1' & \text{if } \alpha = 0 \\ \quad -d(x) + b_1 x^2 + a_2'(1-x)^2 - a_2 & \text{if } \alpha = 2 \\ b_1 x^\alpha + a_2'(1-x)^\alpha - a_2 & \text{otherwise} \end{cases}$$

$$H(x)=\begin{cases}\phi(x)+\phi(1-x)+b_1x+b_2(1-x)+b_3 & \text{if } \alpha=1\\ l_1(1-x)+l_2(1-x)+l_3(x)-l_3(1-x)+b_1-a_1+b_1' & \text{if } \alpha=0\\ \quad -d(x)+b_1x^2+b_2(1-x)^2+a_3 & \text{if } \alpha=2\\ b_1x^\alpha+b_2(1-x)^\alpha+a_3 & \text{otherwise}\end{cases}$$

$$K(x)=\begin{cases}\phi(x)+\phi(1-x)+b_1'x+b_2'(1-x) & \\ \quad +a_1+a_3-b_2-b_3-b_1' & \text{if } \alpha=1\\ l_1(1-x)+l_2(x)-l_3(1-x)+b_1' & \text{if } \alpha=0\\ d(x)+a_1x^2+a_2'(1-x)^2-b_2 & \text{if } \alpha=2\\ a_1x^\alpha+a_2'(1-x)^\alpha-b_2 & \text{otherwise}\end{cases}$$

where $\phi:]0,\infty[\to\mathbb{R}$ *satisfies*

$$\phi(xy)=x\phi(y)+y\phi(x),$$

for all $x,y\in]0,\infty[$, $l_j:]0,\infty[\to\mathbb{R}$ *satisfies*

$$l_i(xy)=l_i(x)+l_i(y)$$

for all $x,y\in]0,\infty[$ *and* $i=1,2,3$, *the function* d *is a real derivation and* a_i,b_i,a_k',b_k' $(i=1,2,3;k=1,2)$ *are arbitrary real constants.*

Gy. Maksa

26. Remark Solution of Problem 17 (1) (of these Proceedings).

In view of Gy. Maksa's solution (see Remark 25 above) to Problem 17 (2), the equation

$$f(x,u)+(1-x)f\left(\frac{y}{1-x},\frac{v}{1-u}\right)=f(y,v)+(1-y)f\left(\frac{x}{1-y},\frac{u}{1-v}\right)\qquad(1)$$

for all $(x,y)\in D_0,(u,v)\in D_0$, where

$$D_0=\{(s,t):s,t,s+t\in]0,1[\}.$$

can be solved as follows.

Keeping u,v constant, (1) goes over into

$$F(x)+(1-x)^\alpha G\left(\frac{y}{1-x}\right)=H(y)+(1-y)^\alpha K\left(\frac{x}{1-y}\right)$$

for all $(x,y)\in D_0$.

From Maksa's solution of this equation ($\alpha=1$).

$$f(s,u)=F(s)=\phi(s)+\phi(1-s)+a_1s+b_1,$$
$$f(s,y)=H(s)=\phi(s)+\phi(1-s)+a_2s+b_2,$$

that is, letting u vary again,

$$f(x,u)=\phi(x)+\phi(1-x)+A(u)x+B(u).\qquad(2)$$

Here

$$\phi(xy)=x\phi(y)+y\phi(x)\qquad(3)$$

(for $x,y\in]0,1[$) and in consequence,

$$\phi\left(\frac{s}{t}\right)=\frac{t\phi(s)-s\phi(t)}{t^2}$$

(where $s, t, \frac{s}{t} \in]0,1[$).

By substituting (2) into (1), we get

$$\begin{aligned}
&\phi(x)+\phi(1-x)+A(u)x+B(u)+\phi(y)-\phi(1-x)+\phi(1-x-y)\\
&\quad+A\left(\frac{v}{1-u}\right)y+B\left(\frac{v}{1-u}\right)(1-x)\\
&=\phi(y)+\phi(1-y)+A(v)y+B(v)+\phi(x)-\phi(1-y)+\phi(1-x-y)\\
&\quad+A\left(\frac{u}{1-v}\right)x+B\left(\frac{u}{1-v}\right)(1-y).
\end{aligned}$$

After cancellations and comparing the coefficients of x and the terms independent of x and y on both sides we get

$$A(u)=A\left(\frac{u}{1-v}\right)+B\left(\frac{v}{1-u}\right)$$

and

$$B(u)-B\left(\frac{v}{1-u}\right)=B(v)+B\left(\frac{u}{1-v}\right)$$

for all $(u,v)\in D_0$. By adding these two equations and writing $C=A+B, p=\frac{u}{1-v}, q=\frac{v}{1-u}$, $(p,q\in]0,1[$, but otherwise arbitrary), we get

$$C(pq)=C(p)+B(1-q)\qquad(p,q\in]0,1[).$$

This is a Pexider type equation with the general solution (cf. [1]) $B(1-q)=l(q), C(u)=l(u)+c$. So

$$B(u)=l(1-u),\qquad A(u)=l(u)-l(1-u)+c$$

where l is an arbitrary solution of

$$l(uv)=l(u)+l(v)\qquad(u,v\in]0,1[),\tag{4}$$

(cf [2],[3]). Since the converse part is obvious, we have proved the following.

Theorem. *The general solution of* (1) *is given by*

$$f(x,u)=\phi(x)+\phi(1-x)+xl(u)+(1-x)l(1-u)+cx,$$

where c is an arbitrary constant and ϕ and l are arbitrary solutions of (3) *and* (4) *respectively.*

Note. *By interchanging (x,y) and (u,v), we can also use Maksa's $\alpha=0$ result for the same purpose.*

New maximal numbers of equilibria in bimatrix games

Bernhard von Stengel

Abstract:
This paper presents a new lower bound of *2.414^d/**sqrt**(d)* on the maximal number of Nash equilibria in *dxd* bimatrix games, a central concept in game theory. The proof uses an equivalent formulation of the problem in terms of pairs of polytopes with *2d* facets in *d*-space. It refutes a recent conjecture that *2^d*-1 is an upper bound, which was proved for *d<5*. The first counterexample is a 6x6 game with 75 equilibria. The case *d=5* remains open. The result carries the lower bound closer to the previously known upper bound of *2.6^d/**sqrt**(d)*.

Discontinuity of Cappings in the Recursively Enumerable Degrees and Strongly Nonbranching Degrees
October 1993, 33 pages

Abstract. We construct an r.e. degree a which possesses a greatest a-minimal pair b0, b1, i.e., r. e. degrees b0 and b1 such that b0,b1 > a, b0 meet b1 = a, and, for any other pair c0 and c1 with these properties, c0 less or equal bi and c1 less or equal b1-i for some i less or equal 1. By extending this result, we show that there are strongly nonbranching degrees which are not strongly noncappable. Finally, by introducing a new genericity concept for r.e. sets, we prove a jump theorem for the strongly nonbranching and strongly noncappable r.e. degrees.

3 B. BORCHERT:
The Complexity of Mind Changes
October 1993, 9 pages
Download Postscript-File

Abstract. The notion of the maximal number of mind changes for a Boolean function was defined and applied in several contexts. An application in complexity theory is the result of Wagner and Wechsung that the classes of the Boolean closure of NP are exactly the classes of the Boolean hierarchy over NP. The aim of this paper is to study the complexity of determining the maximal number of mind changes of a Boolean function if the function is represented as a circuit.

Undecidable Fragments of Elementary Theories
October 1993, 22 pages, 2 pages errata

Abstract. We introduce a general framework to prove undecidability of fragments. This is applied to fragments of theories arising in algebra and recursion theory. For instance, the forall-exist-forall-theory of the class of finite distributive lattices and of the p.o. of recursively enumerable many-one degrees are shown to be undecidable.

Fine Hierarchies and Boolean Terms
November 1993, 28 pages

Abstract. We consider fine hierarchies in recursion theory, descriptive set theory, logic, and complexity theory. Main results state that sets of values of different Boolean terms coincide with levels of suitable fine hierarchies. This gives new short descriptions of these hierarchies and shows that collections of sets of values of Boolean terms are almost well-ordered by inclusion. For the sake of completeness we mention also some earlier results demonstrating usefulness of fine hierarchies.

On the Acceptance Power of Regular Languages
February 1994, 11 pages
Download Postscript-File

Abstract. Hertrampf, Lautemann, Schwentick, Vollmer and Wagner 1993 looked at complexity classes characterized by a regular acceptance language for the words of output bits produced by nondeterministic polynomial-time computations. Here the partial order from Zachos 1988 on relativizable complexity classes is considered which reflects the idea of oracle independent inclusion. The main result will be that this partial order on the complexity classes characterized by regular languages is atomic and therefore not dense. The atoms correspond to the classes NP, coNP and MODpP for p prime.

Predicate Classes and Promise Classes
April 1994, 18 pages
Download Postscript-File

Abstract. Considering computation trees produced by polynomial time nondeterministic computations one can define a complexity class by any predicate on computation trees, such classes will be called predicate classes. It will be shown that these classes are exactly the principal ideals of the polynomial time many-one reducibility. Additionally, the set of classes - which will be called promise classes - definable by promise functions instead of predicates will be shown to be equal to the set of countable ideals.

The Undecidability of the Pi-4-theory for the r.e. wtt- and Turing-degrees
May 1994, 22 pages

Abstract. We show that the Pi-4-theory of the partial order of recursively enumerable weak truth-table degrees is undecidable, and give a new proof of the similar fact for r.e. T-degrees. This is accomplished by introducing a new coding scheme which consists in defining the class of finite bipartite graphs with parameters.

9 V. SELIVANOV:
Refining the Polynomial Hierarchy
July 1994, 20 pages

Abstract. By a result of J.Kadin the difference hierarchy over NP does not collapse if the polynomial hierarchy does not collapse. We extend this to a natural refinement of the polynomial hierarchy of length omega exp. omega. This refinement is generated from the levels of the polynomial hierarchy by the addition modulo 2 and is called here the plus-hierarchy. We consider also two refinements of the plus-hierarchy and discuss their possible applicability to the classification of some languages.

10 V. SELIVANOV:
On Recursively Enumerable Structures
July 1994, 20 pages

Abstract. We state some general facts on r.e. structures, e.g. we show that the free countable structures in quasivarieties are r.e. and construct acceptable numerations and universal r.e. structures in quasivarieties. The last facts are similar to the existence of acceptable numerations of r.e. sets and creative sets. We state a universality property of the acceptable numerations, classify some index sets and discuss their relation to other decision problems. These results show that the r.e. structures behave in some respects better than the recursive structures.

Genericity and Measure for Exponential Time
August 1994, 19 pages

Abstract. Recently Lutz introduced a polynomial time bounded version of Lebesgue measure. He and others used this concept to investigate the quantitative structure of Exponential Time (E=DTIME(2 exp. lin)). Previously, Ambos-Spies, Fleischhack and Huwig introduced polynomial time bounded genericity concepts and used them for the investigation of structural properties of NP (under appropriate assumptions) and E. Here we relate these concepts to each other. We show that, for any c greate or equal 1, the class of (n exp. c)-generic sets has p-measure 1. This allows us to simplify and extend certain p-measure 1-results. To illustrate the power of generic sets we take the Small Span Theorem of Juedes and Lutz as an example and prove a generalization for bounded query reductions.

12 K. AMBOS-SPIES:
On Optimal Polynomial Time Approximations
September 1994, 15 pages

Abstract. Safe and unsafe polynomial time approximations were introduced by Meyer and Paterson [4] and Yesha [8], respectively. The question of which sets have optimal safe approximations was investigated by several authors (see e.g. [3,6,7]). Recently Duris and Rolim [2] considered the unsafe case and compared the existence of optimal polynomial time approximations for both cases. They left open the question, however, whether there are intractable sets with optimal unsafe approximations and whether there are sets with optimal unsafe approximations but without optimal safe approximations. Here we answer these questions affirmatively. Moreover, we consider a variant of Duris and Rolim's Delta-levelability concept related to the nonexistence of optimal unsafe approximations.

13 V.SELIVANOV:
Precomplete Numerations with Applications
October 1994, 59 pages

Abstract. We survey the current stage in the investigation of precomplete numerations and of some their subclasses. Recent results show that many naturally arising numerations are in a sense universal in a suitable class of precomplete numerations. This remarkable fact leads to deep manyfold connections and applications of precomplete numerations to other topics e.g. to hierarchies, index sets, degree structures and fixed point free degrees. We describe these applications in detail, so the paper is also a partial survey of the listed topics.

14 V. SELIVANOV:
Fine Hierarchy of Regular omega-Languages
October 1994, 13 pages

Abstract. By applying descriptive set theory we get several facts on the fine structure of regular omega-languages considered by K.Wagner. We present quite different, shorter proofs for main his results and get new results. Our description of the fine structure is new, very clear and automata-free. We prove also a closure property of the fine structure under Boolean operations. Our results demonstrate deep interconnections between descriptive set theory and theory of omega-languages.

15 K. AMBOS-SPIES, S. A. TERWIJN, X. ZHENG:
Resource Bounded Randomness and Weakly Complete Problems
January 1995, 14 pages

Abstract. We introduce and study resource bounded random sets based on Lutz«s concept of resource bounded measure. We concentrate on (n exp. c)-randomness (c greater or equal 1) which corresponds to the polynomial time bounded (p-) measure and which is adequate for studying the internal and quantitative structure of E=DTIME(2 exp. lin). However we will also comment on E2 = DTIME(2 exp. poly) and its corresponding (p2-) measure. First we show that the class of (n exp. c)-random sets has p-measure 1. This provides a new, simplified approach to p-measure 1-results. Next we compare randomness with genericity (in the sense of Ambos-Spies, Fleischhack and Huwig) and we show that (n exp. (c+1))-random sets are (n exp. c)-generic whereas the converse fails. From the former we conclude that (n exp. c)-random sets are not p-btt-complete for E. Our technical main results describe the distribution of the (n exp. c)-random sets under p-m-reducibility. We show that every (n exp. c)-random set in E has (n exp. k)-

random predecessors in E for any k greater or equal 1 whereas the amount of randomness of the successors is bounded. We apply this result to answer a question raised by Lutz: We show that the class of weakly complete sets has measure 1 in E and that there are weakly complete problems which are not p-btt-complete for E.

16 K. AMBOS-SPIES:
Resource Bounded Genericity
August 1995, 55 pages

Abstract. Resource-bounded genericity concepts have been introduced by Ambos-Spies, Fleischhack and Huwig [AFH84], [AFH88], Lutz [Lu90], and Fenner [Fe91]. Though it was known that some of these concepts are incompatible, the relations among these notions were not fully understood. Here we survey these notions and clarify the relations among them by specifying the types of diagonalizations captured by the individual concepts. Moreover, we introduce two new, stronger resource-bounded genericity concepts corresponding to fundamental diagonalization concepts in complexity theory. First we define general genericity, which generalizes all of the previous concepts and captures both, standard finite extension arguments and slow diagonalizations. The second new concept, extended genericity, actually is a hierarchy of genericity concepts for a given complexity class which extends general genericity and in addition captures delayed diagonalizations. Moreover, this hierarchy will show that in general there is no strongest genericity concept for a complexity class. A similar hierarchy of genericity concepts was independently introduced by Fenner [Fe95]. Finally we study some properties of the Baire category notions on E induced by the genericity concepts and we point out some relations between resource-bounded genericity and resource-bounded randomness.

17 B. BORCHERT, A. LOZANO:
Succinct Circuit Representations and Leaf Languages are Basically the same Concept
July 1995, 6 pages
Download Postscript-File

Abstract. This note connects two topics of Complexity Theory: The topic of succinct circuit representations initiated by Galperin and Wigderson [GW83], and the topic of leaf languages initiated by Bovet et al. [BCS92]. A graph with n nodes can - in the obvious way - be represented more succinctly by a circuit with 2logn input variables which assumes that the nodes are encoded and describes which nodes are connected by edges. This idea can be generalized from graphs to words, so that a circuit describes a word which is possibly exponentially longer. In this note the concept is slightly modified by shifting the length indicator from the circuit output to the problem input. This way, each language A determines its succinct version S(A) consisting of the coded pairs where c is a circuit and m is a binary number such that the length-m prefix of the word described by c is in A. In Bovet et al. [BCS92] it is shown how any language A (the leaf language) determines a complexity class C(A). It will be shown for any language A that its succinct version S(A) is polynomial-time many-one complete for C(A).

Noisy Inference and Oracles
January 1996, 30 pages
Download Postscript-File

Abstract. A learner noisily infers a function or set, if every correct item is presented infinitely often while in addition some incorrect data ("noise") is presented a finite number of times. It is shown that learning from a noisy informant is equal to finite learning with K-oracle from a usual informant. This result has several variants for learning from text and using different oracles. Furthermore, partial identification of all r.e. sets can cope also with noisy input.

20 F. STEPHAN:
Learning via Queries and Oracles
April 1996, 17 pages
Download Postscript-File

Abstract. Inductive inference considers two types of queries: Queries to a teacher about the function to be learned and queries to a non-recursive oracle. This paper combines these two types --- it considers three basic models of queries to a teacher (QEX[Succ], QEX[<] and QEX[+]) together with membership queries to some oracle. The results for each of these three models of query-inference are the same: If an oracle is omniscient for query-inference then it is already omniscient for EX. There is an oracle of trivial EX-degree, which allows nontrivial query-inference. Furthermore, queries to a teacher can not overcome differences between oracles and the query-inference degrees are a proper refinement of the EX-degrees. In the case of finite learning, the query-inference degrees coincide with the Turing degrees. Furthermore oracles can not close the gap between the different types of queries to a teacher.

24 W. MERKLE:
Exact Pairs for Abstract Bounded Reducibilities
November 1996, 20 pages
Download Postscript-File

Abstract. In an attempt to give a unified account of common properties of various resource bounded reducibilities, we introduce conditions on a binary relation \le_{r} between subsets of the natural numbers where \le_{r} is meant as a resource bounded reducibility. The conditions are a formalization of basic features shared by most resource bounded reducibilities which can be found in the literature. As our main technical result, we show that these conditions imply a result about exact pairs which has been previously shown by Ambos-Spies in a setting of polynomial time bounds: given some recursively presentable \le_{r}-ideal \cal{I} and some recursive \le_{r}-hard set B for \cal{I} which is not contained in \cal{I}, there is some recursive set C where B and C are an exact pair for \cal{I}, that is, \cal{I} is equal to the intersection of the lower \le_{r}-cones of B and C where C is not in \cal{I}. In particular, if the relation \le_{r} is in addition transitive and there are least sets, then every recursive set which is not in the least degree is half of a minimal pair of recursive sets.

25 F. STEPHAN:
On One-Sided Versus Two-Sided Classification
December 1996, 26 pages
Download Postscript-File

Abstract. One-sided classifiers are computable devices which read the characteristic function of a set and output a sequence of guesses which converges to 1 iff the set on the input belongs to the given class. Such a classifier is two-sided if the sequence of its output in addition converges to 0 on sets not belonging to the class. The present work obtains the below mentioned results for one-sided classes (= Σ^0_2 classes) w.r.t.\ four areas: Turing complexity, 1-reductions, index sets and measure. There are one-sided classes which are not two-sided. This can have two reasons: (1) the class has only high Turing complexity. Then there are some oracles which allow to construct noncomputable two-sided classifiers. (2) The class is difficult because of some topological constraints and then there are also no nonrecursive two-sided classifiers. For case (1), several results are obtained to localize the Turing complexity of certain types of one-sided sets. The concepts of 1-reduction, 1-completeness and simple sets is transferred to one-sided classes: There are 1-complete classes and simple classes, but no class is at the same time 1-complete and simple. The one-sided classes have a natural numbering. Most of the common index sets relative to this numbering have the high complexity Π^1_1: the index sets of the class $\{0,1\}^{\infty}$, the index set of the equality problem and the index set of all two-sided classes. On the other side the index set of the empty class has complexity Π^0_2; Π^0_2 and Σ^0_2 are the least complexities any non-trivial index set can have. Any one-sided class is measurable. It is shown that a one-sided class has effective measure 0 if it has measure 0, but that there are one-sided classes having measure 1 without having measure 1 effectively. The measure of a two-sided class can be computed in the limit.

26 S. KAUFMANN, F. STEPHAN:
Robust Learning with Infinite Additional Information
December 1996, 18 pages
Download Postscript-File

Abstract. The present work investigates Gold style algorithmic learning from input-output examples whereby the learner has access to oracles as additional information. Furthermore this access has to be robust, that means that a single learning algorithm has to succeed with every oracle which meets a given specification. The first main result considers oracles of the same Turing degree: Robust learning with any oracle from a given degree does not achieve more than learning without any additional information. The further work considers learning from function oracles which describe the whole class of functions to be learned in one of the following four ways: the oracle is a list of all functions in this class or a predictor for this class or a one-sided classifier accepting just the functions in this class or a martingale succeeding on this class. It is shown that for learning in the limit (Ex), lists are the most powerful additional information, the powers of predictors and classifiers are incomparable and martingales are of no help at all. Similar results are obtained for the criteria of predicting the next value, finite, Popperian and finite Popperian learning. Lists are omniscient for the criterion of predicting the next value but some classes can not be Ex-learned with any of these types of additional information. The class REC of all recursive functions is Ex-learnable with the help of a list, a predictor or a classifier.

Structural Properties of Bounded Relations with an Application to NP Optimization Problems
December 1996, 16 pages
Download Postscript-File

Abstract. We introduce the notion bounded relation which comprises most resource bounded reducibilities to be found in the literature, including non-uniform reducibilities such as $\le ^ {{\cal P}/poly}$. We state conditions on bounded relations which imply that every countable partial ordering can be embedded into every proper interval of the recursive sets, respectively functions. As corollaries, e obtain that every countable partial ordering can be embedded into every proper interval of $(REC,\le^{{\cal P}/poly}$, as well as into every proper interval between two maximization, respectively two minimization problems in the structures $(NPO, \le_E)$ and $(NPO,\le_L)$. We derive the results on the two latter structures by first representing maximization and minimization problems, respectively, by functions in $\omega^ \omega$, then showing that the reducibilities induced on $\omega^\omeg$ by the relations $\le_L $ and $\le_E$ satisfy our assumptions. For these relations, we show further that the result about partial order embeddings extends to lattice embeddings of arbitrary countable distributive lattices where in addition the least or the greatest element of the lattice can be preserved. Among other corollaries, we obtain from the result on lattice embedding that every non-trivial $\cal NP$ optimization problem bounds a minimal pair.

Effective Baire Category Concepts
March 1997, 17 pages
Download Postscript-File

Abstract. Mehlhorn (1973) introduced an effective Baire category concept designed for measuring the size of classes of computable sets. This concept is based on effective extension functions. By considering partial extension functions, we introduce a stronger concept. Similar resource-bounded concepts have been previously introduced by Ambos-Spies et al. (1988) and Ambos-Spies (1996). By defining a new variant of the Banach-Mazur game, we give a game theoretical characterization of our category concept.

On the Structures Inside Truth-Table Degrees
October 1997, 42 pages
Download Postscript-File

Abstract. The following theorems on the structure inside nonrecursive truth-table degrees are established: D\"egtev's result that the number of bounded truth-table degrees inside a truth-table degree is at least two is improved by showing that this number is infinite. There are even infinite chains and antichains of bounded truth-table degrees inside the truth-table degrees which implies an affirmative answer to a question of Jockusch whether every truth-table degree contains an infinite antichain of many-one degrees. Some but not all truth-table degrees have a least bounded truth-table degree. The technique to construct such a degree is used to solve an open problem of Beigel, Gasarch and Owings: there are Turing degrees (constructed as hyperimmune-free truth-table degrees) which consist only of 2-subjective sets and do therefore not contain any objective set. Furthermore a truth-table degree consisting of three positive degrees is constructed where one positive degree consists of enumerable semirecursive sets, one of co-enumerable semirecursive sets and one of sets, which are neither enumerable nor co-enumerable nor semirecursive. So Jockusch's result that there are at least three positive degrees inside a truth-table degree is optimal. The number of positive degrees inside a truth-table degree can also be some other odd integers as for example nineteen, but it is never an even finite number.

Separating NP-Completeness Notions under Strong Hypotheses
November 1997, 29 pages
Download Postscript-File

Abstract. Lutz[16] proposed the study of the structure of the class NP=NTIME(poly) under the hypothesis that NP does not have p-measure 0 (with respect to Lutz's resource bounded measure [15]). Lutz and Mayordomo [18] showed that, under this hypothesis, NP-m-completeness and NP-T-completeness differ, and they conjectured that further NP-completeness notions can be separated. Here we prove this conjecture for the bounded-query reducibilities. In fact we consider a new weaker hypothesis, namely the assumption that NP is not p-meager with respect to the resource bounded Baire category concept of Ambos-Spies et al. [2]. We show that this category hypothesis is sufficient to get:
(i) For k>=2, NP-btt(k)-completeness is stronger than NP-btt(k+1)-completeness.
(ii) For k>=1, NP-bT(k)-completeness is stronger thanNP-bT(k+1)-completeness.
(iii) For every k^k-2, NP-bT(k-1)-completeness is not implied by NP-btt(k+1)-completeness and NP-btt(2^k-2)-completeness is not implied by NP-bT(k)-completeness.
(iv) NP-btt-completeness is stronger than NP-tt-completeness.

Abstract. We study the interplay between Turing degrees $\bd$ and nontrivial factors of groups of all $\bd$--recursive permutations. We prove that the isomorphism type of any such factor group completely determines the degree $\bd$ and describe the definability of Turing degrees by elementary properties of these groups.
We reduce the study of elementary properties of these groups to the study of properties of degrees, being considered as classes of sets, in the first order language of arithmetics with added unary predicate.

Lattice Embeddings for Abstract Bounded Reducibilities
April 1998, 92 pages
Download Postscript-File

Abstract. We give an abstract account of resource bounded reducibilities as exemplified by the polynomial time or logarithmically space bounded reudcibilities of Turing, truth-table, and many one type. We introduce a small set of axioms which are satisfied for most of the specific resource bounded reducibilities which appear in the literature. Some of the axioms are of a more algebraic nature, such as the requirement that the reducibility under consideration is a reflexive relation, while others are formulated in terms of recursion theory and for example are related to delayed computations of arbitrary recursive sets. We discuss basic consequences of these axioms and their relation to previous axiomatic approaches by Mehlhorn [31], Schmidt [41], Mueller [37], and, in a context of relativized Blum measure, by Lynch et al. [26]. As main technical result we show that for every reducibility which satisfies our axioms, every countable distributive lattice can be embedded into every proper interval of the structure induced on the recursive sets. This result extends a corresponding result for polynomial time bounded reducibilities due to Ambos-Spies [1], as well as work by Mehlhorn [31]. Mehlhorn shows from an apparently more restricitve set of assumptions that the recursive sets form a dense structure and claims that in fact every countable partial ordering can be embedded into every proper interval of the recusive sets.

Learning Algebraic Structures from Text
July 1998, 48 pages
Download Postscript-File

Abstract. The present work investigates the learnability of classes of substructures of some algebraic structure: submonoids and subgroups of some given group, ideals of some given commutative ring, subfields of a vector space. The learner sees all positive data but no negative one and converges to a program enumerating or computing the set to be learned. Besides semantical (BC) and syntactical (Ex) convergence also the more restrictive ordinal bounds on the number of mind changes are considered. The following is shown:
(a) Learnability depends much on the amount of semantic knowledge given at the synthesis of the learner where this knowledge is represented by programs for the algebraic operations, codes for prominent elements of the algebraic structure (like 0 and 1 in fields) and certain parameters (like the dimension of finite dimensional vector spaces). For several natural examples good knowledge of the semantics may enable to keep ordinal mind change bounds while restricted knowledge may either allow only BC-convergence or even not permit learnability at all.
(b) The class of all ideals of a recursive Noetherian ring is BC-learnable iff the ring is Noetherian. Furthermore, one has either only a BC-learner outputting enumerable indices or one can already get an Ex-learner converging to decision procedures and respecting an ordinal bound on the number of mind changes. The ring is Artinian iff the ideals can be Ex-learned with a constant bound on the number of mind changes, this constant is the length of the ring. Ex-learnability depends not only on the ring but also on the representation of the ring. Polynomial rings over the field of rationals with n variables have exactly the ordinal mind change bound~$ \omega^n$ in the standard representation. Similar results can be established for unars. Noetherian unars with one functioncan be learned with an ordinal mind change bound $a \omega $ for some~a.

A Note on Recursively Approximable Real Numbers
July 1998, 7 pages
Download Postscript-File

Abstract. In [1] Weihrauch and Zheng compare some notions of recursively approximable real numbers. Their two main results - stated in the terminology of [1] - are: There is a weakly computable real number which is not semi-computable, and there is a recursively enumerable real number which is not weakly computable. In [1] these theorems are directly proved by finite-injury arguments, where the proof of the first result uses the observation that the real corresponding to a d-r.e. set is weakly comutable. Here, by further exploring the relations between the computability properties of a real number and the location of the corresponding set in the difference hierarchy over the r.e. sets, we show that the two main results in [1] can be obtained from theorems on the r.e., d-r.e., and omega-r.e. degrees in the literature.

The Complexity of Universal Text-Learners
October 1998, 18 pages
Download Postscript-File

Abstract. The present work deals with language learning from text. It considers universal learners for classes of languages in models of additional information and analyzes their complexity in terms of Turing-degrees. The following is shown: If the additional information is given by a set containing at least one index for each language from the class to be learned but no index for any language outside the class then there is a universal learner having the same Turing degree as the inclusion problem for recursively enumerable sets. This result is optimal in the sense that any further learner has the same or higher Turing degree. If the additional information is given by the index set of the class of languages to be learned then there is a computable universal learner. Furthermore, if the additional information is presented as an upper bound on the size of some grammar that generates the language then a high oracle is necessary and sufficient. Finally, it is shown that for the concepts of finite learning and learning from good examples, the index set of the class to be learned gives insufficient information: these criteria need due to the restrictive convergence-constraints the jump of the index set instead of the index set itself. So they have infinite access to the information of the index set in finite time.

Predictive Learning Models for Concept Drift
November 1998, 26 pages
Download Postscript-File

Abstract. Concept drift means that the concept about which data is obtained may shift from time to time, each time after some minimum permanence. Except for this minimum permanence, the concept shifts may not have to satisfy any further requirements and may occur infinitely often. Within this work is studied to what extent it is still possible to predict or learn values for a data sequence produced by drifting concepts. Various ways to measure the quality of such predictions, including martingale betting strategies and density and frequency of correctness, are introduced and compared with one another. For each of these measures of prediction quality, for some interesting concrete classes, usefully established are (nearly) optimal bounds on permanence for attaining learnability. The concrete classes, from which the drifting concepts are selected, include regular languages accepted by finite automata of bounded size, polynomials of bounded degree, and exponentially growing sequences defined by recurrence relations of bounded size. Some important, restricted cases of drifts are also studied, for example, the case where the intervals of permanence are computable. In the case where the concepts shift only among finitely many possibilities from certain infinite, arguably practical classes, the learning algorithms can be considerably improved.

Collapsing Polynomial-Time Degrees
March 1999, 24 pages
Download Postscript-File

Abstract. For reducibilities r and s such that r is weaker than s, we say that the r-degree of A, i. e., the class of sets which are r-equivalent to A, collapses to the s-degree of A if both degrees coincide. We investigate for the polynomial-time bounded many-one, bounded truth-table, truth-table, and Turing reducibilities whether and under which conditions such collapses can occur. While we show that such collapses do not occur for sets which are hard for exponential time, we have been able to construct a recursive set such that its bounded truth-table degree collapses to its many-one degree. The question whether there is a set such that its Turing degree collapses to its many-one degree is still open; however, we show that such a set - if it exists - must be recursive.

Separation by Random Oracles and Almost Classes for Generalized Reducibilities
March 1999, 22 pages
Download Postscript-File

Abstract. Let C be the class of all sets (of natural numbers) and let $\le_r$ and $\le_s$ be two binary relations on C which are meant as reducibilities. Let both relations be closed under finite variation (of their set arguments) and consider the uniform distribution on C, which is obtained by choosing elements of C by independent tosses of a fair coin. Then we might ask for the probability that the lower $\le_r$-cone of a randomly chosen set X, that is, the class of all sets A with $A \le_r X$, differs from the lower $\le_s$-cone of X. By closure under finite variation, the Kolmogorov 0-1 law yields immediately that this probability is either 0 or 1; in case it is 1, the relations are said to be separable by random oracles. Again by closure under finite variation, for every given set A, the probability that a randomly chosen set X is in the upper cone of A w.r.t. $ \le_r$ is either 0 or 1. Let $Almost_r$ be the class of sets for which the upper cone w.r.t. $\le_r$ has measure 1. In the following, results about separations by random oracles and about Almost classes are obtained in the context of generalized reducibilities, that is, for binary relations on C

which can be defined by a countable set of total continuous functionals on C in the same way as the usual resource bounded reducibilities are defined by an enumeration of appropriate oracle Turing machines. The concept of generalized reducibility comprises all natural resource bounded reducibilities, but is more general; in particular, it does not involve any kind of specific machine model or even effectivity. The results on generalized reducibilities yields corollaries about specific resource bounded reducibilities, including several results which have been shown previously in the setting of time or space bounded Turing machine computations.

Dot Operators
April 1999, 18 pages
Download Postscript-File

Abstract. Well-known examples of dot operators are the existential, the counting, and the BP-operator. We will generalize this notion of a dot operator so that every language A will determine an operator A dot. In fact we will introduce the more general notion of promise dot operators for which the BP-operator is an example. Dot operators are a refinement of the leaf language concept because the class determined by a leaf language A equals A dot P. Moreover we are able to represent not only classes but reducibilities, in fact most of the known polynomial-time reducibilities can be represented by dot operators. We show that two languages determine the same dot operator if and only if they are reducible to each other by polylog-time computable monotone projections.

Simple sets and strong reducibilities
October 1999, 25 pages
Download Postscript-File

Abstract. We study connections between strong reducibilities and properties of computably enumerable sets such as simplicity. We call a class S of computably enumerable sets bounded iff there is an m-incomplete computably enumerable set A such that every set in S is m-reducible to A. For example, we show that the class of effectively simple sets is bounded; but the class of maximal sets is not. Furthermore, the class of computably enumerable sets Turing reducible to a computably enumerable set B is bounded iff B is low2. For r = bwtt, tt, wtt and T, there is a bounded class intersecting every computably enumerable r-degree; for r = c, d and p, no such class exists.

46 F. STEPHAN:
Degrees of Computing and Learning
Habilitationsschrift, November 1999, 163 pages
Download Postscript-File

Abstract. The present work focuses on oracles, in particular on computation and learning with the help of an oracle. Oracles allow the analysis of the difficulty of learning and computing problems. For example, the difficulty to check whether an enumerable set W given by its index e is infinite needs an oracle capable to compute the halting problem relative to the halting problem K. In learning theory, Adleman and Blum (AB91) showed that exactly the high oracles allow to Ex-learn the class REC of all total recursive functions. Also the difference between learning models has been analyzed in terms of the oracles necessary to make a problem S learnable with respect to some more pretentious Model 2 provided that the S is already learnable without the help of any oracle with respect to a less pretentious Model 1. The usefulness of the oracles with respect to a computation or learning task induces canonically a degree-structure on the oracles. Such degree-structures are research topics in their own right and there are numerous results on the degree-structures induced by computing (mostly on Turing, enumeration and many-one degrees). The present work (in particular in Chapter 2) gives an overview on the results about the degree-structures induced by learning.
For Turing reducibility, the question whether B is at least as powerful than A is equivalent to the question whether A can be computed relative to B, whence in this setting, degrees and their closures downward are always countable. In learning, an oracle B might be more powerful than A without giving any possibility to compute A relative to B, even in the limit. For example, Ex-learning has one uncountably infinite degree, namely the one of those oracles which allow to Ex-learn all classes of recursive functions. The structure of Ex-degrees is coarser than that of the Turing degrees. Only very restricted learning models like finite learning (Fin) generate the same degree-structure as the Turing reducibility.
Chapters 3 combines the notions of queries to oracles and of queries to teachers. Such a teacher answers questions --- posed in a specific query language --- on the function f to be learned. So the learner has more data on f as in the standard case. This extra-knowledge can sometimes be non-trivially combined with an oracle: There is an oracle A of trivial Ex-degree, which together with a teacher can learn a class S which can neither be learned from the oracle A alone nor from the teacher alone (Theorem 3.3.5).
An important research topic is the question to which extent errors and false information in the data-stream disturb learning. Many models of noisy data have the disadvantage that the disturbances do not only make learning difficult but do also permit identical data-streams for different concepts. Chapter 4 proposes a popular concept of noise which solves this problem: the basic idea is that each correct data-item occurs infinitely often while each incorrect one occurs only finitely often. Although each single item can be false, the data-stream as a whole determines which items are correct and which incorrect so that the function to be learned is uniquely determined by the data-stream. The central result is that Ex-learning functions from such data has a nice characterization in terms of learning with oracles: S is Ex-learnable from noisy data iff S is finitely learnable from noise-free data with the help of the oracle K.
The topic of Chapters 5 and 6 is the learning of sets and functions with infinite additional information. In both cases, the additional information is required to describe the whole class of languages to be learned and it must not be specific for a single set or function in S. Chapter 5 deals with various types of index-sets for classes of languages: if a set B contains for every language in S some index but no indices for languages outside S then a learner with a Turing degree which can solve the halting problem relative to the halting problem K can learn S with access to this oracle B. Such a learner is even class-independent since it works for every principally learnable S when the corresponding B is supplied. If B is an index-set in the classical sense, that is, if B contains exactly the indices e of the sets in S, then the learner can even be chosen to be recursive. In Chapter 5 it was required that the algorithm is universal in the sense that it worked for every S which is principally learnable, that is, learnable relative to some oracle. In contrast to this, the setting investigated in Chapter 6 permits that the algorithms are specific for the class S to be learned. However, the algorithms still have to be robust in the sense that they

succeed with every oracle meeting the specification. Degree-theoretic descriptions of the oracle do not help much: if the learning-algorithm must be able to learn S with every oracle from a given m-degree then one can learn S even without an oracle. In contrast to this, syntactic descriptions of the class S turn out to be more helpful. The most powerful tools are lists of the functions in S. The considered syntactic descriptions are related to learning criteria, whence Chapter 6 is also some kind of study to which extent it is possible to translate learners of one type (represented by the oracle) uniformly into learners of an other type (represented by the learning algorithm using the oracle).
Classification is related to learning in the sense that, like a learner, a classifier reads the characteristic function of a given set A as a learner but converges only to 1 in the case that A is in the class S to be classified or converges to 0 in the case that A is not in the class S. This notion of two-sided classification can also be weakened to one-sided classification where the classifier on sets outside the class only outputs infinitely often a 0 without being required to converge to 0. Chapter 7 analyzes the relations between these two notions and the question, which oracles enable to transform a given one-sided classifier into a two-sided one.
While the preceding chapters focus on degree-structures more general than that of the Turing reducibility, Chapter 8 investigates the structures induced by stronger reducibility notions, mainly by those of truth-table reducibility and its even more restrictive variants. The central question is whether there are always infinitely many positive and bounded truth-table degrees inside a truth-table degree. Degtev (1973) showed that the number of bounded truth-table degrees inside a truth-table degree is at least 2. This result is improved by showing that this number in fact is always infinite. Moreover, there are infinite chains and antichains of bounded truth-table degrees inside every truth-table degree. The latter implies an affirmative answer to a question of Jockusch (1969) whether every truth-table degree contains an infinite antichain of many-one degrees. Some but not all truth-table degrees have a least bounded truth-table degree. The technique to construct such a degree is used to solve an open problem of Beigel, Gasarch and Owings (1989): There are Turing degrees (constructed as hyperimmune-free truth-table degrees) which consist only of 2-subjective sets and do therefore not contain any objective set. Furthermore, a truth-table degree consisting of three positive degrees is constructed where one positive degree consists of enumerable semirecursive sets, one of coenumerable semirecursive sets and one of sets, which are neither enumerable nor coenumerable nor semirecursive. So Jockusch's result that there are at least three positive degrees inside a truth-table degree is optimal. The number of positive degrees inside a truth-table degree can also be some other odd integers as for example nineteen, but it is never an even finite number.

Almost Complete Sets
June 2000, 18 pages
Download Postscript-File

Abstract. We show that there is a set which is almost complete but not complete under polynomial-time many-one (p-m) reductions for the class **E** of sets computable in deterministic time 2^{lin}. Here a set A in a complexity class C is almost complete for C under some reducibility r if the class of the problems in C which do not r-reduce to A has measure 0 in C in the sense of Lutz's resource-bounded measure theory. We also show that the almost complete sets for **E** under polynomial-time bounded one-one length-increasing reductions and truth-table reductions of norm 1 coincide with the almost p-m-complete sets for **E**. Moreover, we obtain similar results for the class **EXP** of sets computable in deterministic time 2^{poly}.

Learning Power and Language Expressiveness
July 2000, 19 pages
Download Postscript-File

Abstract. The topic of the present work is to study the relationship between the power of the learning algorithms on the one hand, and the expressive power of the logical language which is used to represent the problems to be learned on the other hand. The central question is whether enriching the language results in more learning power. In order to make the question relevant and nontrivial, it is required that both texts (sequences of data) and hypotheses (guesses) be translatable from the ``rich'' language into the ``poor'' one.
The issue is considered for several logical languages suitable to describe structures whose domain is the set of natural numbers. It is shown that enriching the language does not give any advantage for those languages which define a monadic second-order language being decidable in the following sense: there is a fixed interpretation in the structure of natural numbers such that the set of sentences of this extended language true in that structure is decidable. But enriching the original language even by only one constant gives an advantage if this language contains a binary function symbol (which will be interpreted as addition).
Furthermore, it is shown that behaviourally correct learning has exactly the same power as learning in the limit for those languages which define a monadic second-order language with the property given above, but has more power in case of languages containing a binary function symbol. Adding the natural requirement that the set of all structures to be learned is recursively enumerable, it is shown that it pays off to enrich the language of arithmetics for both finite learning and learning in the limit, but it does not pay off to enrich the language for behaviourally correct learning.

Learning How to Separate
January 2001, 24 pages
Download Postscript-File

Abstract. The main question addressed in the present work is how to find effectively a recursive function separating two sets drawn arbitrarily from a given collection of disjoint sets. In particular, it is investigated in which cases it is possible to satisfy the following additional constraints: confidence where the learner converges on all data-sequences; conservativeness where the learner abandons only definitely wrong hypotheses; consistency where also every intermediate hypothesis is consistent with the data seen so far; set-driven learners whose hypotheses are independent of the order and the number of repetitions of the data-items supplied; learners where either the last or even all hypotheses are programs of total recursive functions. The present work gives an overview of the relations between these notions and succeeds to answer many questions by finding ways to carry over the corresponding results from other scenarios within inductive inference. Nevertheless, the relations between conservativeness and set-driven inference needed a novel approach which enabled to show the following two major results:
(1) There is a class for which recursive separators can be found in a confident and set-driven way, but no conservative learner finds a (not necessarily total) separator for this class.
(2) There is a class for which recursive separators can be found in a confident and conservative way, but no set-driven learner finds a (not necessarily total) separator for this class.

Refuting Learning Revisited
April 2001, 29 pages
Download Postscript-File

Abstract. We consider, within the framework of inductive inference, the concept of refuting learning as introduced by Mukouchi and Arikawa, where the learner is not only required to learn all concepts in a given class but also has to explicitly refute concepts outside the class.
In the first part of the paper, we consider learning from text and introduce a concept of limit-refuting learning that is intermediate between refuting learning and reliable learning. We give characterizations for these concepts and show some results about their relative strength and their relation to confident learning.
In the second part of the paper we consider learning from texts that for some k contain all positive Π_k-formulae that are valid in the standard structure determined by the set to be learned. In this model, the following results are shown. For the language with successor, any countable axiomatizable class can be limit-refuting learned from Π_1-texts. For the language with successor and order, any countable axiomatizable class can be reliably learned from Π_1-texts and can be limit-refuting learned from Π_2-texts, whereas the axiomatizable class of all finite sets cannot be limit-refuting learned from Π_1-texts. For the full language of arithmetic, which contains in addition plus and times, for any even k there is an axiomatizable class that can be limit-refuting learned from Π_{k+2}-texts but not from Π_{k}-texts. A similar result with k+3 in place of k+2 holds with respect to the language of Presburger's arithmetic.

Abstract. Barzdins conjectured that only recursively enumerable classes of functions can be learned robustly. This conjecture, which was finally refuted by Falk, initiated the study of notions of robust learning. The present work surveys research on robust learning and focusses on the recently introduced variants of uniformly robust and hyperrobust learning. Proofs are included for the (already konwn) results that uniformly robust Ex-learning is more restictive than robust Ex-learning, that uniformly robustly Ex-learnable classes are consistently learnable, that hyperrobustly Ex-learnable classes are in Num and that some hyperrobustly BC-learnable class is not in Num.

Counting Extensional Differences in BC-Learning
April 2002, 17 pages
Download Postscript-File

Abstract. Let BC be the model of behaviourally correct function learning as introduced by Barzdins and Case and Smith. We introduce a mind change hierarchy for BC, counting the number of extensional differences in the hypotheses of a learner. We compare the resulting models BC_n to models from the literature and discuss confidence, team learning, and finitely defective hypotheses. Among other things, we prove that there is a tradeoff between the number of semantic mind changes and the number of anomalies in the hypotheses. We also discuss consequences for language learning. In particular we show that, in contrast to the case of function learning, the family of classes that are confidently BC-learnable from text is not closed under finite unions.

On the Learnability of Vector Spaces
October 2002, 21 pages
Download Postscript-File

Abstract. The central topic of the paper is the learnability of the recursively enumerable subspaces of $V_{\infty }/V$, where $V_{\infty }$ is the standard recursive vector space over the rationals with countably infinite dimension, and V is a given recursively enumerable subspace of $V_{\infty }$. It is shown that certain types of vector spaces can be characterized in terms of learnability properties: $V_{\infty }/V$ is behaviourally correct learnable from text iff V is finite dimensional, $V_{\infty }/V$ is behaviourally correct learnable from switching the type of information iff V is finite dimensional, 0-thin, or 1-thin. On the other hand, learnability from informant does not correspond to similar algebraic properties of a given space. There are 0-thin spaces W_{1} and W_{2} such that W_{1} is not explanatorily learnable from informant and the infinite product $(W_{1})^{\infty }$ is not behaviourally correct learnable, while W_{2} and the infinite product $(W_{2})^{\infty }$ are both explanatorily learnable from informant.

Learning by Switching Type of Information
October 2002, 19 pages
Download Postscript-File

Abstract. The present work is dedicated to the study of modes of data-presentation in the range between text and informant within the framework of inductive inference. In this study, the learner alternatingly requests sequences of positive and negative data. We define various formalizations of valid data presentations in such a scenario. We resolve the relationships between these different formalizations, and show that one of these is equivalent to learning from informant. We also show a hierarchy formed (for each of the formalizations studied) by considering the number of switches between requests for positive and negative data.

Abstract. We characterize FIN-, EX- and BC-learning, as well as the corresponding notions of team learning, in terms of isolated branches on effectively given sequences of trees. The more restrictive models of FIN-learning and strong-monotonic BC-learning are characterized in terms of isolated branches on a single tree. Furthermore, we discuss learning with additional information where the learner receives an index for a strongly recursive tree such that the function to be learned is isolated on this tree. We show that EX-learning with this type of additional information is strictly more powerful than EX-learning.

Martin-Löf Random and PA-complete sets
November 2002, 8 pages
Download Postscript-File

Abstract. A set A is Martin-Löf random iff the class {A} does not have Sigma^0_1-measure 0. A set A is PA-complete if one can compute relative to A a consistent and complete extension of Peano Arithmetic. It is shown that every Martin-Löf random set either permits to solve the halting problem K or is not PA-complete. This result implies a negative answer to the question of Ambos-Spies and Kucera whether there is a Martin-Loef random set not above K which is also PA-complete.

Classes with Easily Learnable Subclasses
February 2003, 20 pages
Download Postscript-File

Abstract. It is well-known that infinite recursively enumerable sets have infinite recursive subsets. Similarly, one can study the relation between identifiable classes and subclasses which are identifiable under a more restrictive criterion. The chosen framework is inductive inference, in particular the criterion of explanatory learning (Ex) of recursive functions as introduced in Gold in 1967. Among the more restrictive criteria is finite learning, where the learner outputs on every function to be learned exactly one hypthesis which has to be correct. The topic of the present paper are the natural variants (a) and (b) below of the classical question whether a given learning criterion like finite learning is more restrictive than Ex-learning. (a) Does every infinite

Ex-identifiable class have an infinite finitely identifiable subclass? (b) If an infiite Ex-identifiable class S has an infinite finitely identifiable subclass, does it necessarily follow that some appropriate learner Ex-identifies S as well as finitely identifies an infinte subclass of S? These questions are also treated in the context of ordinal mind change bounds.

Trivial Reals
February 2003, 26 pages
Download Postscript-File

Abstract. Solovay showed that there are noncomputable reals α such that $H(\alpha \upharpoonright n) \leq H(1^n)+O(1)$, where H the prefix-free Kolmogorov complexity. Such H-*trivial*reals are interesting due to the connection between algorithmic complexity and effective randomness. We give a new, easier construction of an H-trivial real. We also analyze various computability-theoretic properties of the H-trivial reals, showing for example that no H-trivial real can compute the halting problem. Therefore, our construction of an H-trivial computably enumerable set is an easy, injury-free construction of an incomplete computably enumerable set. Finally, we relate the H-trivials to other classes of "highly nonrandom" reals that have been previously studied.

Automatic Forcing and Genericity: On the Diagonalization Strength of Finite Automata
Juni 2003, 24 pages
Download Postscript-File

Abstract. Algorithmic and resource-bounded Baire category and corresponding genericity concepts introduced in computability theory and computational complexity theory, respectively, have become elegant and powerful tools in these settings. Here we introduce some new genericity notions based on extension functions computable by finite automata which are tailored for capturing diagonalizations over regular sets and functions. We show that the generic sets obtained either by the partial regular extension functions of any given fixed constant length or by all total regular extension of constant length are just the sets with saturated (also called disjunctive) characteristic sequences. Here a sequence α is saturated if every string occurs in α as a substring. We also show that these automatic generic sets are not regular but may be context free. Furthermore, we introduce stronger automatic genericity notions based on regular extension functions of nonconstant length and we show that the corresponding generic sets are bi-immune for the classes of regular and context free languages.

Infinitely-Often Autoreducible Sets
Juni 2003, 16 pages
Download Postscript-File

Abstract. A set A is autoreducible if one can compute, for all x, the value A(x) by querying A only at places y different from x. Furthermore, A is infinitely-often autoreducible if, for infinitely many x, the value A(x) can be computed by querying A only at places y different from x; for all other x, the computation outputs a special symbol to signal that the reduction is undefined. It is shown that for polynomial time Turing and truth-table autoreducibility there are sets A, B, C in EXP such that A is not infinitely-often Turing autoreducible, B is Turing autoreducible but not infinitely-often truth-table autoreducible, C is truth-table autoreducible with g(n)+1 queries but

not infinitely-often Turing autoreducible with g(n) queries. Here n is the length of the input, g is nondecreasing and there exists a polynomial p in n that bounds the computation time and values of g. Furthermore, connections between notions of infinitely-often autoreducibility and notions of approximability are investigated. The Hausdorff-dimension of the class of sets which are not infinitely-often autoreducible is shown to be 1.

Abzählen von Sehnendiagrammen und Asymptotik von Vassiliev-Invarianten
On enumeration of chord diagrams and asymptotics of Vassiliev invariants

|Zusammenfassung| |Inhaltsverzeichnis| |Ergänzende Angaben|

Zusammenfassung

Der Gegenstand dieser Arbeit ist die Kombinatorik von Sehnendiagrammen und Asymptotik von Vassiliev-Invarianten.
In den Abschnitten 2 und 3 werden wir einige (reine) Abzählresultate über Sehnendiagramme herleiten. Obwohl nicht direkt in Beziehung zu Vassiliev-Invarianten, verdeutlichen sie die kombinatorische Komplexität der Sehnendiagramme -- schon für einfache Eigenschaften wird die Abzählung kompliziert und erfordert zusätzliche Ideen.
Im Abschnitt 4 werden wir kombinatorische Techniken benutzen, um Abzählung bestimmter Sehnendiagramme mit Vassiliev-Invarianten in Verbindung zu bringen, und werden eine obere Abschätzung der Anzahl der Vassiliev-Invarianten in Abhängigkeit vom Grad herleiten.
Im Abschnitt 5 werden wir mit Hilfe der Techniken aus Abschnitt 4 und dem Resultat von Chmutov und Duzhin eine untere Abschätzung der Anzahl aller Vassiliev-Invarianten herleiten und die Beziehung zwischen der Anzahl der primitiven und aller Vassiliev-Invarianten diskutieren. Parallel dazu werden wir alles, was über Asymptotik von Vassiliev-Invarianten bekannt ist, zusammenfassen.
Im Abschnitt 6 werden wir schliesslich mit Hilfe der Methode der Verzopfungsreihen exponentielle obere Schranken für die Anzahl der Vassiliev-Invarianten auf Knoten von beschränktem Zopfindex und arboreszenten Knoten herleiten.
Teile dieser Dissertation können in mehreren Arbeiten von mir gefunden werden.

Title: A Recurring Reoccurance in Counting Permutations

Student: Yan Zhang

2002-2003

Background:
If we define a_n to be the number of square permutations of size n, then a_n follows a curious recurrence: a_(2n) (2n+1) = a_(2n+1). The original paper analyzing this sequence was written by Blum in an article in 1974. A proof exists, though needing some non-trivial generating functions techniques, and offers nothing to a combinatorial understanding of the pattern. Richard Stanley revisited this problem in his text "Enumerative Combinatorics" (1999). The paper gives the basic definitions and mathematical notation necessary, though some elementary knowledge in combinatorics would be helpful. Otherwise, it is easy to understand.

Description:
(Includes Exam component 3)
This research was started at the Clay Mathematics Institute. Our "team" was consisted of Philip Sung (CA) and me, under the guidance of other Academy participants, conducted by Dr. Richard Stanley of MIT.
We were looking at the integer sequence a_n which enumerates the number of square permutations of fixed length n (mathematical background, including the definition of square permutations, can be found in the paper below). In 1974, when this sequence was analyzed, a difficult proof with advanced combinatorics was given to prove that the sequence satisfied the recurrence a_(2n) (2n+1) = a_(2n+1). Our task was to prove this with elementary combinatorics, which gives a clearer picture of what is actually happening in the strucutre of the problem.
After some work at the Institute, we managed to give a combinatorial proof. However, what is interesting is not just that such a proof have been found, but rather that we've discovered a certain independence inside this problem, i.e. we can generalize the problem to a whole class of similar sequences, in each one the recurrence will occur again.
To handle this, we created our own mathematical definition, the concept of "Odd-cycle invariance". We have also proved that the general class of sequences which satisfy this invariance also satisfies the given recurrence.
We are working hard to generalize this result, namely to classify such sequences in more complicated context.

Visuals, files, tables:

Following things may or may not be included here in the future: data tables, the mathematica notebooks, and transparencies for the presentation.

The Notebook (Mathematica format) This is the (not commented) mathematica notebook from which values were achieved for the desired (and other) sequences.

The Paper:
(Includes exam components 1 - 2)
The Paper (Incomplete) (PDF) This paper is not yet complete, but contains the main elements of the proof. Some parts are handwavy, and we haven't included data tables yet.
The Paper (Incomplete) (HTML Above created with latex2html. Really messy.

The Scientific Method:
The Scientific Method As required, here's a look at the project via the scientific method.

The Future:
(Includes exam components 4 and 5)
By the end of the fourth quarter, with already a good head start, I shoudl be able to finish the final version of the paper including the main proof and new mahematical strucutres introduced in the proof. All I have remaining to do is to clean up the language, make sure that the proofs work, find more similar sources to extract information from, and inserting tables. Then we will have a finalized, professional-looking paper suitable for submission to a mathematical jounral.
However, I am also actively trying to go in new directions. Many of these directions were outlined in the Scientific Method link about:
*Are there other types of invariance in permutations which follow a similar pattern? If so, how do we prove that they work also?
*How can we generalize this counting technique to other sequences, and not just counting permutations?
*In our proof, we have found that the analogue of our simple counting technique can be reinforced by ann application of generating functions. From this, can we find a deeper connection between the algebra of generating functions and the combinatorial theory of bijective proofs.
Any breakthrough in these directions would call for additional work on the paper.

As for college plans, seeing that my mentors are from MIT, and that I will probably go to college in Boston, further research is certainly possible. The mathematics involved also isn't very intricate, so I can take a good advanced course of combinatorics no matter where I go to foster the project's improvement. A bright future indeed.

Abstract

We introduce a transformation of finite integer sequences, show that every sequence eventually stabilizes under this transformation and that the number of fixed points is counted by the Catalan numbers. The sequences that are fixed are precisely those that describe themselves — every term t is equal to the number of previous terms that are smaller than t. In addition, we provide an easy way to enumerate all these self-describing sequences by organizing them in a Catalan tree with a specific labelling system.

Prefix ordered sequences and rooted labelled trees

The following connection between prefix ordered sequences and rooted labelled trees is well known and we briefly mention only the instance which is useful for our considerations.

Let $\mathcal{A}$ be the set of finite integer sequences $a = (a_0, a_1, \dots)$ with the property that $0 \leq a_i \leq i$, for all indices. We order the sequences in $\mathcal{A}$ by the *prefix* relation, i.e.,

$$(a_0, a_1, \dots, a_n) \preceq (b_0, b_1, \dots, b_m)$$

if $n \leq m$ and $a_i = b_i$, for $i = 0, \dots, n$. The sequences in $\mathcal{A}$ can be organized in a rooted labelled tree $\mathcal{T}$ which reflects the prefix order relation. The root of the tree $\mathcal{T}$ is labelled by 0. Every vertex that is at distance n from the root has $n + 2$ children labelled by $0, 1, \dots, n, n+1$ (see Figure 1). The vertices whose distance to the root is n form the n-th *level* of the tree $\mathcal{T}$, which is also called the n-th *generation*. For every vertex v at the level n in the tree $\mathcal{T}$ there exist a unique path of length n from the root to v. The labels of the vertices on this path form a unique sequence $(a_0, a_1, \dots, a_n)$ in $\mathcal{A}$ that corresponds to the vertex v and this sequence is called the *full name* of v. The correspondence

$$v \leftrightarrow \text{the full name of } v$$

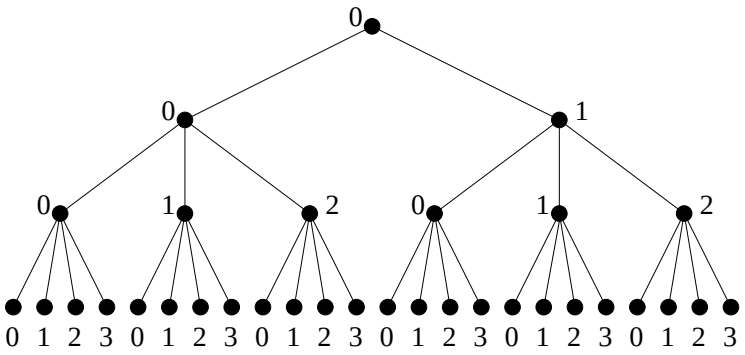

Figure 1: The rooted labelled tree $\mathcal{T}$ up to the third generation

provides a bijection between the vertices in $\mathcal{T}$ and the sequences in $\mathcal{A}$. Under this bijection, the vertices from the n-th generation in $\mathcal{T}$ correspond to the sequences of length $n+1$ in $\mathcal{A}$. The set of vertices in the n-th generation is denoted by $\mathcal{T}_n$ and the corresponding set of sequences by $\mathcal{A}_n$.

The sequence $a = (a_0, a_1, \ldots, a_n)$ is a prefix of the sequence $b = (b_0, b_1, \ldots, b_m)$ if and only if the vertex v_a with full name a is on the unique path between the root and the vertex v_b with full name b, i.e., if and only if the vertex v_a is an ancestor of the vertex v_b. Consider a graph endomorphism α of $\mathcal{T}$ that fixes the root (and therefore also preserves the levels). Such an endomorphism corresponds to a transformation of sequences $\alpha : \mathcal{A} \to \mathcal{A}$ that preserves the length of the sequences and also their prefix order, i.e.,

$$a \preceq b \qquad \text{implies} \qquad \alpha a \preceq \alpha b,$$

for all sequences a and b in $\mathcal{A}$.

In the sequel, we often deliberately blur the distinction between the vertices in $\mathcal{T}$ and the corresponding sequences in $\mathcal{A}$. Similarly, we do not distinguish tree endomorphisms of $\mathcal{T}$ fixing the root from sequence transformations that preserve the length and the prefix order. This mistake actually improves our presentation.

Let α be an endomorphism of $\mathcal{T}$. Since every generation in $\mathcal{T}$ is finite, the α *orbit*

$$\alpha^* u = \{\alpha^i u \mid i \geq 0\}$$

of every vertex u of $\mathcal{T}$ is finite. Thus, starting from any vertex, repeated applications of α produce *periodic points*, i.e., points a for which $\alpha^k a = a$ for some $k > 0$. The *period* of the periodic point a is the smallest k for which $\alpha^k a = a$. The points of period 1 are *fixed points* and the points of period dividing 2 are *double points*. Obviously, if u and v are periodic points of α and u is a prefix of v then the period of u divides the period of v.

Sometimes it is easy to estimate how long does it take before a periodic point is reached. We make use of the *lexicographical ordering* $\leq$ of the sequences in $\mathcal{A}_n$ (note the difference with the prefix ordering $\preceq$). Namely, for $a = (a_0, a_1, \ldots, a_n)$ and $b = (b_0, b_1, \ldots, b_n)$, set $a < b$ if $a_i < b_i$ at the first index where a and b differ.

Theorem 1. *Let α be an endomorphism of the tree $\mathcal{T}$ and assume that, for some $n \geq 1$, there exists $k \geq 1$ such that, for every vertex u in generation n, either*

$$u \leq \alpha^k u \leq \alpha^{2k} u \leq \dots$$

or

$$u \geq \alpha^k u \geq \alpha^{2k} u \geq \dots .$$

Then, starting from any point in generation n, repeated applications of α lead to a periodic point of period dividing k is reached in $O(n^2)$ steps.

Proof. We show that $\beta = \alpha^k$ reaches a fixed point in no more than

$$1 + 2 + \cdots + n = n(n+1)/2$$

steps.

Start with any vertex u in generation n. Without loss of generality we may assume

$$u \leq \beta u \leq \beta^2 u \leq \dots .$$

After the first application of β the initial segment up to index 1 of βu is fixed under β. After the next two steps the entry at index 2 will be fixed. Proceeding in the same fashion we see that the initial segment of $\beta^{1+2+\cdots+k}u$ up to index k is fixed under β. Indeed, once the initial segment up to index $k-1$ is fixed the entry at index k can go up no more than k times (from 0 to k) before it stabilizes. Thus, $\beta^{1+2+\cdots+n}u$ is fixed under β. □

Self-describing sequences

We define an endomorphism $\delta : \mathcal{A} \to \mathcal{A}$ transforming sequences in $\mathcal{A}$ by

$$(\delta a)_i = \#\{j \mid j < i,\ a_j < a_i\}.$$

Thus, for each term t in the sequence a, $(\delta a)_i$ counts the number of previous terms that are smaller than t. The transformation δ makes perfect sense even for sequences out of $\mathcal{A}$, but the image is in $\mathcal{A}$ and it stays there under further iterations. A sequence that is fixed under δ is called a *self-describing sequence*. Therefore, the sequence $a = (a_0, a_1, \dots)$ is self-describing if

$$\#\{j \mid j < i,\ a_j < a_i\} = a_i,$$

for all indices, i.e., every term t is equal to the number of previous terms that are smaller than t.

The Catalan family tree

We describe now a rooted labelled subtree of $\mathcal{T}$, denoted by $\mathcal{C}$ and called *the Catalan family tree* or just the *Catalan family*. The root vertex 0 belongs to $\mathcal{C}$. It has two children named 0 and 1 and we consider 0 the older sibling. The oldest sibling in this family always

has 2 children, the second oldest 3, the third oldest 4, and so on. The oldest child of a member of the family x gets named after the oldest sibling of x, the second oldest child after the second oldest sibling, and so on, until x uses its own name for its second to last child and n for the youngest one, where n is the generation number of the children (the level in the tree). The diagram in Figure 2 depicts the family members of $\mathcal{C}$ up to the third generation.

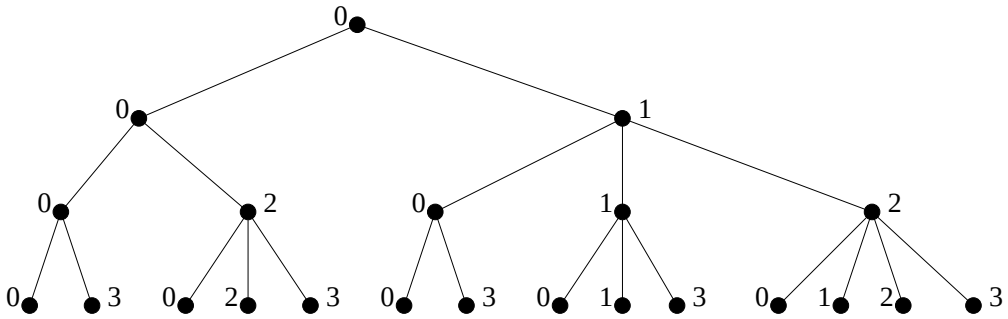

Figure 2: The Catalan family tree $\mathcal{C}$ up to the third generation

The connection

We establish now a connection between the self-describing sequences and the Catalan family tree.

Theorem 2. *The full names of the members of the Catalan family are precisely the self-describing sequences. In other words, they are the fixed points of the endomorphism δ.*

Moreover, repeated applications of δ to any sequence in $\mathcal{A}$ eventually produce a member of the Catalan family, i.e. a fixed point of δ. The number of applications needed to reach such a point is $O(n^2)$.

All statements of the theorem are implied by Theorem 1 and the following lemma.

Lemma 1. *If a is a member of the Catalan family then $a = \delta a$. Otherwise, $a < \delta a$.*

Proof. The proof is by induction on the generation number n. The statement is true for $n = 0$ and $n = 1$. Assume that the statement is true for all vertices up to the n-th generation.

Let

$$a = (a_0, a_1, \ldots, a_n, x)$$

be a $(n+1)$-st generation member of the Catalan family. We consider two cases.

If $x = n + 1$ then

$$\#\{j \mid j < n+1,\ a_j < x\} = \#\{j \mid j < n+1,\ a_j < n+1\} = n + 1 = x,$$

and a is a fixed point of δ.

If $x \neq n+1$, then $a_n \geq x$ and there exists an n-th generation member of the Catalan family whose full name is

$$a' = (a_0, a_1, \ldots, a_{n-1}, x),$$

namely the one after whom a was named. We have

$$\#\{j \mid j < n+1,\ a_j < x\} = \#\{j \mid j < n,\ a_j < x\} = x,$$

where the first equality comes from the fact that $a_n \geq x$ and the second from the inductive hypothesis, since $\delta a' = a'$.

Thus all members of the Catalan family are fixed under δ.

Now, let

$$a = (a_0, a_1, \ldots, a_n, x)$$

be a full name of a vertex in $\mathcal{T}$ in the n-th generation that is not a member of the Catalan family $\mathcal{C}$. If any proper prefix of a is not in $\mathcal{C}$ we obtain the claim directly from the inductive hypothesis. Thus we may assume that

$$a'' = (a_0, a_1, \ldots, a_n)$$

is a member of the Catalan family. Since a is not in $\mathcal{C}$ we have $a_n \neq x$ and $n+1 \neq x$. We consider two cases.

If $a_n > x$ then $a' = (a_0, a_1, \ldots, a_{n-1}, x)$ is not in $\mathcal{C}$ and

$$\#\{j \mid j < n+1,\ a_j < x\} = \#\{j \mid j < n,\ a_j < x\} > x,$$

where the equality comes from the fact that $a_n > x$ and the inequality from the inductive hypothesis.

If $a_n < x < n+1$ then

$$\#\{j \mid j < n+1,\ a_j < x\} = \#\{j \mid j < n,\ a_j < x\} + 1 \geq x+1,$$

where the equality comes from the fact that $a_n < x$ and the inequality from the inductive hypothesis. The equality in the last case is possible only when $a' = (a_0, a_1, \ldots, a_{n-1}, x)$ is in $\mathcal{C}$. □

We proceed by counting the self-describing sequences with fixed length. In addition, we obtain a result on the distribution of names in $\mathcal{C}$. Recall that the n-th Catalan number is equal to

$$c_n = \frac{1}{n+1}\binom{2n}{n}.$$

A recursive definition of the Catalan numbers is given by

$$c_0 = 1,$$
$$c_{n+1} = c_0 c_n + c_1 c_{n-1} + \cdots + c_n c_0.$$

Theorem 3. *The number of self-describing sequences in $\mathcal{A}_n$, i.e., the number of n-th generation members of the Catalan family is the $(n+1)-th$ Catalan number c_{n+1}.*

Moreover, for $r = 0, \ldots, n$, the number of n-th generation members of the Catalan family whose name is r is equal to $c_r c_{n-r}$.

Proof. Denote by z_n the number of n-th generation members of the Catalan family whose name is 0. More generally, for $r = 0, \ldots, n$ denote by $f_{n,r}$ the number of n-th generation members of the Catalan family whose name is r. Finally, denote by g_n the number of n-th generation members of the Catalan family.

Since the oldest child of every member of the Catalan family is named 0, we have, for all n,

$$z_{n+1} = g_n.$$

Since the youngest sibling in the r-th generation is always named r and the oldest 0 we also have, for all r,

$$f_{r,r} = f_{r,0} = z_r.$$

For some fixed r, consider the set of $f_{r,r}$ r-th generation members named r together with all their descendants in $\mathcal{C}$ whose names are greater or equal to r. This forest of $f_{r,r}$ identical subtrees of $\mathcal{C}$ contains all members of $\mathcal{C}$ whose name is r. Moreover, each tree in this forest looks exactly like the Catalan family tree, except that all labels are increased by r. Indeed, each r-th generation member od $\mathcal{C}$ named r has two children, named r and $r+1$, the oldest sibling always has two children, the second oldest three, etc. Thus, for any n and $r = 0, \ldots, n$, the number $f_{n,r}$ of n-th generation members of $\mathcal{C}$ named r is $f_{r,r}$ times larger than the number of $(n-r)$-th generation members of $\mathcal{C}$ named 0, i.e.,

$$f_{n,r} = f_{r,r} f_{n-r,0} = z_r z_{n-r}.$$

Since $z_0 = 1$ and

$$\begin{aligned} z_{n+1} = g_n &= f_{n,0} + f_{n,1} + \cdots + f_{n,n} \\ &= z_0 z_n + z_1 z_{n-1} + \cdots + z_n z_0 \end{aligned}$$

we conclude that, for all n, z_n is the $n-th$ Catalan number. The statements of the theorem follow now easily from the relations $g_n = z_{n+1}$ and $f_{n,r} = z_r z_{n-r}$. □

Connection to other Catalan trees and objects

It is well known that the Catalan numbers appear naturally under many circumstances. The exercises on Catalan numbers in [Sta99] provide a trove of examples, along with references, in which Catalan numbers count the number of objects of particular type and size. The self-describing sequences provide yet another example that we now relate to some other objects counted by the Catalan numbers.

Consider the sequences in $\mathcal{A}$ with the property that $a_{i+1} \leq a_i + 1$, for all indices (see the Exercise 6.19.u in [Sta99]). Such sequences are called *sequences with unit increase.*

The rooted labelled tree that corresponds to the set of sequences with unit increase looks the same as the Catalan family tree, just with a different labelling and we obtain an easy bijective correspondence between the self-describing sequences and the sequences with unit increase. We could use this bijective connection to show that the Catalan numbers count the number of self-describing sequences. Instead, we provided a direct proof of Theorem 3 and the reason is that there is an important difference in the distribution of labels in the Catalan family tree and the tree of the sequences with unit increase.

Theorem 4. *For $r = 0, \ldots, n$, the number of n-th generation vertices in the tree of sequences with unit increase labelled by r is*

$$\frac{r+1}{n+1}\binom{2n-r}{n}.$$

Proof. Let $a = (a_0, a_1, \ldots, a_n)$ be a sequence with unit increase. Following Exercise 6.19.u in [Sta99], we define, for $i = 0, \ldots, n-1$,

$$b_i = a_i - a_{i+1} + 1.$$

Construct a sequence of n 1's and $n - a_n$ negative 1's by replacing each b_i, $i = 0, \ldots, n-1$ by one 1 followed by b_i negative 1's. The newly obtained sequence has non-negative partial sums. The correspondence between the sequences in $\mathcal{A}_n$ with unit increase that end by r and the sequences of n 1's and $n - r$ negative 1's with non-negative partial sums is bijective. It is shown in [Bai96] that the number of sequences with non-negative partial sums that consist of n 1's and k negative 1's is equal to

$$\frac{n+1-k}{n+1}\binom{n+k}{n}$$

and this implies our claim. □

In passing, we make a slightly more general remark. Namely, for a fixed positive integer m, consider the sequences with the property that $a_0 = 0$ and $0 \leq a_{i+1} \leq a_i + m$, for all indices. Such sequences are called *sequences with m-increase*. We can easily construct the rooted labelled tree that corresponds to such sequences. For a sequence $(a_0, a_1, \ldots, a_n)$ with m-increase, define, for $i = 0, \ldots, n-1$,

$$b_i = a_i - a_{i+1} + m.$$

Following the same approach as before, construct a sequence of n m's and $n - a_n$ negative 1's by replacing each b_i, $i = 0, \ldots, n-1$ by one m followed by b_i negative 1's. The newly obtained sequence has non-negative partial sums and the correspondence between the sequences $(a_0, a_1, \ldots, a_n)$ with m-increase that end by r and the sequences of n 1's and $mn - r$ negative 1's with non-negative partial sums is bijective. Such sequences are discussed in [FS01], where simple recursive formulae for their number is provided.

Unfortunately, closed formulae are not provided yet, but we note that the number of n-th generation sequences with m-increase is given by $c_m(n+1)$ where

$$c_m(n) = \frac{1}{mn+1}\binom{(m+1)n}{n}.$$

The last displayed number is the generalization of the Catalan numbers which counts, for example, the number of rooted $(m+1)$-ary trees with n interior vertices.

It is worth nothing that Julian West [Wes95] recursively constructs a rooted labelled tree whose root is labelled by 2 and each vertex labelled by x has x children labelled by $2, 3, \ldots, x+1$. This tree, which West calls a Catalan tree, looks again exactly like the Catalan family tree, but with different labels. In fact, the tree of the sequences with unit increase can be obtained from the Catalan tree constructed by Julian West by decreasing all labels by 2.

Similarly, in the spirit of the Julian West construction, for any positive integer m, construct a rooted labelled tree whose root is labelled by $m+1$ and each vertex labelled by x has x children labelled by $m+1, m+2, \ldots, m+x$. The tree of sequences with m-increase can be obtained from this tree by decreasing all labels by $m+1$.

Mirror symmetry and mutually describing sequences

We introduce another endomorphism $\gamma : \mathcal{A} \to \mathcal{A}$ transforming sequences in $\mathcal{A}$ by

$$(\gamma a)_i = \#\{j \mid j < i,\ a_j \geq a_i\}.$$

Clearly $\gamma = \mu\delta$ where μ is the *mirror involution* of $\mathcal{A}$ given by

$$(\mu a)_i = i - a_i.$$

We call μ the mirror involution of $\mathcal{A}$ since μ mirrors the tree $\mathcal{T}$ through its vertical axis of symmetry.

The endomorphism γ is studied in [Šun02]. Clearly, γ has no fixed points other than the sequence (0). However, γ has a lot of double points. If a is a double point of γ then so is $b = \gamma a$. Moreover, then $\gamma b = a$ and the sequences a and b mutually describe each other.

Theorem 5 ([Šun02]). *Repeated applications of γ to any sequence in $\mathcal{A}$ eventually produce a double point of γ. The number of application needed to reach a double point in $\mathcal{A}_n$ is $O(n^2)$ and there are more than 2^n such points.*

The sequence that counts the number of double points of γ in the n-th generation starts as follows

$$1, 2, 4, 10, 26, 70, 216, \ldots$$

This sequence does not appear in the Encyclopedia of Integer Sequences [SP95] nor in the online version [Slo] as of January 2002. It is interesting that we have such a good

understanding of the fixed points of δ, via the Catalan family tree, but we were still not able to count the number of double points of the mirror related endomorphism $\gamma = \mu\delta$.

Some other endomorphisms leading to fixed or double points are studied in [Šun02]. For one of them, the set of double points of length n is in bijective correspondence with the Young tableaux of size n.

The Ehrenfeucht-Mycielski Sequence

K. Sutner

Computer Science Department

Pittsburgh, PA 15213
sutner@cs.cmu.edu

Abstract. We study the disjunctive binary sequence introduced by Ehrenfeucht and Mycielski in [1]. The match length associated to the bits of the sequence is shown to be a crucial tool in the analysis of the sequence. We show that the match length between two consecutive bits in the sequence differs at most by 1 and give a lower bound for the limiting density of the sequence. Experimental computation in the `automata` package has been very helpful in developing these results.

1 The Ehrenfeucht-Mycielski Sequence

An infinite sequence is *disjunctive* if it contains all finite words as factors. In [1] Ehrenfeucht and Mycielski introduced a method of generating a disjunctive binary sequence based on avoiding repetitions. To construct the Ehrenfeucht-Mycielski (EM) sequence U, start with a single bit 0. Suppose the first n bits $U_n = u_1 u_2 \dots u_n$ have already been chosen. Find the longest suffix v of U_n that appears already in U_{n-1}. Find the last occurrence of v in U_{n-1}, and let b be the first bit following that occurrence of v. Lastly, set $u_{n+1} = \overline{b}$, the complement of b. It is understood that if there is no prior occurrence of any non-empty suffix the last bit in the sequence is flipped. The resulting sequence starts like so:

$$0100110101110001000011110110010100100111 0$$

see also sequence A038219 in Sloane's catalog of integer sequences, [2]. The in the title of their paper the authors ask somewhat tongue-in-cheek how random their sequence is. As a first step towards understanding the properties of U they show that U is indeed disjunctive and conjecture that the limiting density of 1's is $1/2$.

1.1 Preliminary Data

To get a better understanding of U it is natural to generate a few thousand bits of the EM sequence using standard string matching algorithms. In a high-level environment such as Mathematica, see [3], a few lines of code suffice for this. In our work we use an automata theory package built on top of Mathematica that provides a number of tools that are helpful in the analysis of U, see [4]

Fig. 1. The first 2^{12} bits of the Ehrenfeucht-Mycielski sequence.

for a recent description of the package. The first 2^{12} bits, in row-major order, are shown in figure 1. The pattern seems surprisingly indistinguishable from a random pattern given the simplicity of the definition of the sequence.

More interesting is a plot of the census function for U: nearly all words of length k appear already among the first 2^k bits of the sequence. Thus, an initial segment of the EM sequence behaves almost like a de Bruijn sequence, see [5]. Define the *cover* $\mathsf{cov}(W)$ of a word W, finite or infinite, to be the set of all its finite factors, and $\mathsf{cov}_k(W) = \mathbf{2}^k \cap \mathsf{cov}(W)$. Here we write $\mathbf{2}$ for the two-symbol alphabet $\{0, 1\}$. The census function $C_k(n) = |\mathsf{cov}_k(U_n)|$ for the EM sequence increases initially at a rate of 1, and, after a short transition period, becomes constant at value 2^k. In figure 2, the green line stands for $k = 9$, blue for $k = 10$, and red for $k = 11$.

Another surprising picture emerges when one considers the length of the longest suffix v of $U_n = u_1 u_2 \dots u_n$ that matches with a previous occurrence. We write $\mu(n)$ for the suffix, and $\lambda(n) = |\mu(n)|$ for its length. As with the census function, the match length function λ increases in a very regular fashion. Indeed, in most places the length of the match at position n is $\lfloor \log_2 n \rfloor$. To visualize λ it is best to collapse runs of matches of the same length into a single data point. The plot 3 uses the first 2^{15} bits of the sequence. It is immediate from the definitions that the match length can never increase by more that 1 in a single step. The plot suggests that the match lengths also never drop by more than 1 in a single step, a fact that will be established below. The data also suggest that the match length function is nearly monotonic: once the first match of length k has occurred, all future matches are of length at least $k-2$. If true, this property would imply balance of the EM sequence, see section 3.

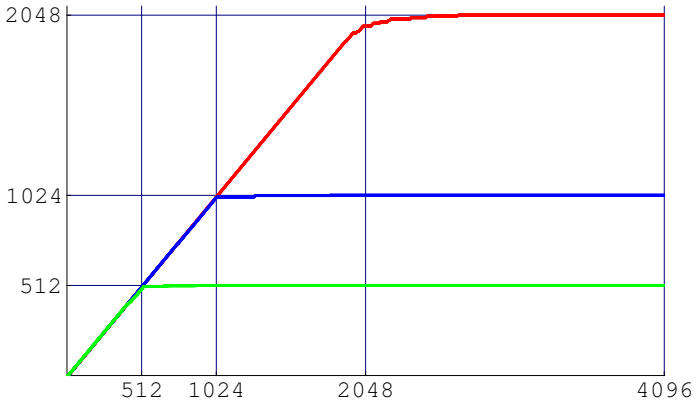

Fig. 2. The census function for the Ehrenfeucht-Mycielski sequence for words of lengths $k = 9, 10, 11$.

1.2 Generating Long Initial Segments

Clearly it would be helpful to test whether the patterns observed in the first few thousands of bits extend to longer initial segments, say, the first few million bits. To generate a million bits one has to resort to faster special purpose algorithms. As far as the complexity of U is concerned, it is clear that the language $\mathsf{pref}(U)$ of all prefixes of U fails to be regular. Hence it follows from the gap theorem in [6] that $\mathsf{pref}(U)$ cannot be context-free. The obvious practical approach is to use a variant of the KMP algorithm. Suppose k was the length of the previous match. We can scan U_n backwards and mark the positions of the nearest matches of length $k-2, k-1, k, k+1$. If no such match appears we have to revise the near-monotonicity conjecture from above. Of course, the scan can be terminated immediately if a match of length $k+1$ appears. If one implements this algorithm in an efficient language such as C++ it is straightforward to generate a few million bits of U.

Much better results can be achieved if one abandons pattern matching entirely and uses an indexing algorithm instead. In essence, it suffices to maintain, for each finite word w of some fixed length at most k, the position of the last occurrence of that word in the prefix so far constructed. This is done in brute-force tables and quite straightforward except at places where the match length function assumes a new maximum. A detailed description of the algorithm can be found in [7]. The reference shows that under the assumption of near-monotonicity discussed in section 1.3 one can generate a bit of the sequence in amortized constant time. Moreover, only linear space is required to construct an initial segment of the sequence, so that a simple laptop computer suffices to generate the first billion bits of the sequence in less than an hour.

As far as importing the bits into `automata` there are two choices. Either one can read the precomputed information from a file. Note, though, that storing

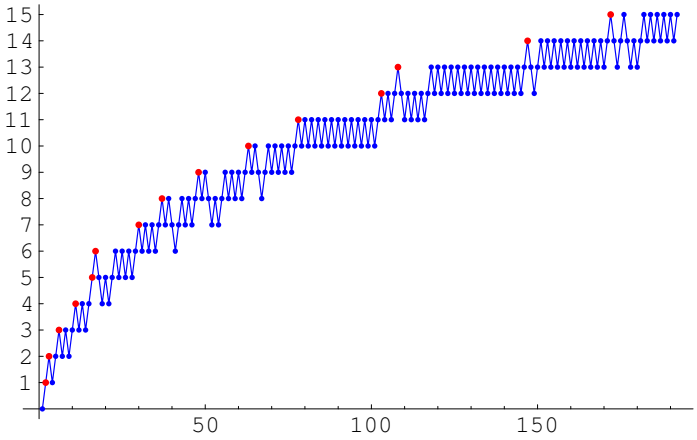

Fig. 3. Changes in the match lengths of the first 2^{15} bits of the Ehrenfeucht-Mycielski sequence.

the first billion bits in the obvious bit-packed format requires 125 million bytes, and there is little hope to decrease this amount of space using data compression: the very definition of the EM sequence foils standard algorithms. For example, the Lemple-Ziv-Welch based `gzip` algorithm produces a "compressed" file of size 159,410 bytes from the first million bits of the EM sequence. The Burrows-Wheeler type `bzip2` algorithm even produces a file of size 165,362 bytes.

The other options exploits the fact that Mathematica offers a communication protocol that allows one to call external programs directly from the kernel. This feature is used in `automata` extensively to speed up crucial algorithms.

1.3 Assorted Conjectures

It is clear from data plots as in the last section that the EM sequence has rather strong regularity properties and is indeed far from random. In their paper [1] Ehrenfeucht and Mycielski ask if their sequence is balanced in the sense that the limiting frequency of 0's and 1's is 1/2. More precisely, for any non-empty word $x \in \mathbf{2}^*$ let $\#_1 x$ be the number of 1's in x. Define the *density* of x to be $\Delta(x) = \frac{\#_1 x}{|x|}$. The following conjecture is from [1]:

Conjecture 1. Balance
In the limit, the density of U_n is 1/2.

Convergence seems to be very rapid. E.g., $\Delta(U_{2000000}) = 1000195/2000000 = 0.5000975$. It is shown in [8] that the density is bounded away from 0, and the argument given below provides a slightly better bound, but the balance conjecture remains open. To show balance, it suffices to establish the following property of the match length function.

Conjecture 2. Near Monotonicity
Any match of length k is followed only by matches of length at least $k-2$.

Near monotonicity implies rapid convergence of the density. We will prove a weaker a monotonicity property, namely that any match of length k is followed only by matches of length at least $k/2$. This suffices to show that the limiting density is bounded away from 0. Another interesting property of U is the rapid growth of the census function, simultaneously for all k.

Conjecture 3. Growth Rate
Any word of length k appears in the first $O(2^k)$ bits of the sequence.

As a matter of fact, a bound of 2^{k+2} appears to suffice, but it is unclear what the growth rate of the number of words that fail to appear already at time 2^{k+1} is. We originally conjectured a bound of 2^{k+1} but had to revise it after Hodsdon computed the first billion bits of the sequence, see [7]. The last two conjectures hold true for the first billion bits of the sequence.

We note in passing another apparent structural property that becomes visible from the data. The plot of the match lengths suggests that they grow in a very regular fashion. It is natural to inquire about the position of the match in U_n, i.e., the position of the nearest occurrence of the suffix v in U_n associated with the next bit. Figure 4 shows the positions of the first 2^{14} matches. The available range of positions for the matches forms a staircase, with a few outliers, and the match positions essentially form square blocks of size 2^k. The outliers are due to the internal dynamics of the sequence, see section 2.2 below, but match positions are very poorly understood at present.

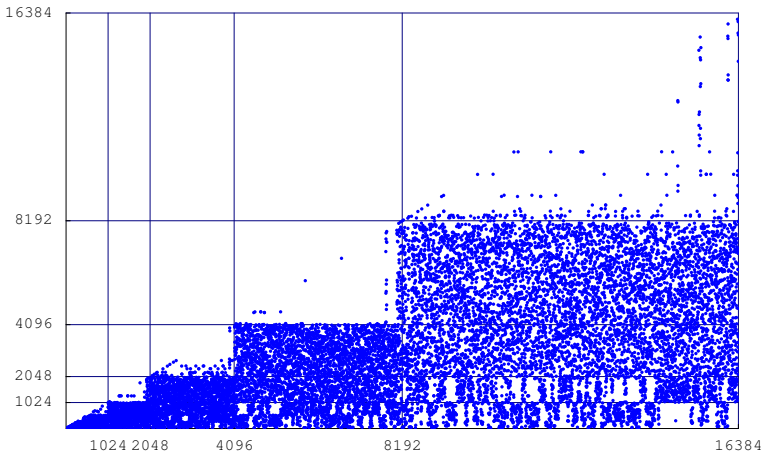

Fig. 4. Match positions in the first 2^{14} bits of the Ehrenfeucht-Mycielski sequence.

2 Recurrence and the Internal Clock

With a view towards computational support, it is convenient to think of the EM sequence as tracing a path in a de Bruijn $\mathcal{B}_k$. We write $\mathcal{B}_k(n)$ for the subgraph of $\mathcal{B}_k$ induced by the edges that lie on the path traced by U_n. Likewise, $\overline{\mathcal{B}}_k(n)$ denotes the complement of $\mathcal{B}_k(n)$, i.e., the subgraph obtained by removing all the edges that lie on the path traced by U_n. We also assume that isolated vertices are removed. It is easy in `automata` to generate and inspect these graphs for a reasonably wide range of parameters. This type of experimental computation turned out to be very helpful in the discovery of some of the results in the next section, and in avoiding dead-ends in the development of some of the proofs.

As a first step towards the analysis of the dynamics of U, from the definition of U we have the following fact.

Proposition 1. *Alternation Principle*
If a vertex u in $\mathcal{B}_k(n)$ appears twice in U_{n-1} it has out-degree 2.

As we will see, the condition for alternation is very nearly the same as having in-degree 2. It is often useful to consider the nodes in $\mathcal{B}_k$ that involve a subword v of length $k-1$. Clearly, there are exactly four such nodes, and they are connected by an alternating path of the form:

$$a\,v \rightarrow v\,b \leftarrow \overline{a}\,v \rightarrow v\,\overline{b} \leftarrow a\,v$$

We will refer to this subgraph as the *zigzag* of v. Since $\mathcal{B}_k$ is the line graph of $\mathcal{B}_{k-1}$, the zigzag of v corresponds to the node v and its 4 incident edges in $\mathcal{B}_{k-1}$. It follows from the last proposition that the path U can not touch a zigzag arbitrarily.

Proposition 2. *No Merge Principle*
The path U can not touch a zigzag in exactly two edges with the same target.

In particular v is a match if, and only if, all the nodes in the zigzag of v have been touched by U.

2.1 The Second Coming

Since we are dealing with a binary sequence one might suspect the initial segments U_{2^k} to be of particular interest, a suspicion borne out by figures 2 and 4. However, it turns out that there are other, natural stages in the construction of the EM sequence associated with the first repetition of the initial segments of the sequence. They determine the point where the census function first deviates from linear growth. First, a simple observation concerning the impossibility of repeated matches. Note that the claim made here is easy to verify using some of the graph algorithms in `automata`.

Proposition 3. *Some initial segment U_n of U traces a simple cycle in $\mathcal{B}_k$, anchored at vertex U_k. Correspondingly, the first match of length k is U_k.*

Proof. Since U is infinite, it must touch some vertex in $\mathcal{B}_k$ twice. But by proposition 2 the first such vertex can only be U_k, the starting point of the cycle. □

The proposition suggests to define $\Lambda(t) = \max\big(\, \lambda(s) \;\big|\; s \le t \,\big)$ to be the length of the longest match up to time t. Thus, Λ is monotonically increasing and changes value only at the second occurrence of an initial segment. We write τ_k for the time when U_k is encountered for the second time. Note that we have the upper bound $\tau_k \le 2^k + k - 1$ since the longest simple cycle in $\mathcal{B}_k$ has length 2^k. The fact that initial segments repeat provides an alternative proof of the fact that U is disjunctive, see [1] for the original argument.

Lemma 1. *The Ehrenfeucht-Mycielski sequence U is disjunctive.*

Proof. It follows from the last proposition that every factor of U occurs again in U. Now choose n sufficiently large so that $H = \mathcal{B}_k(n) = \mathcal{B}_k(m)$ for all $m \ge n$. Since every point in H is touched by U at least twice, it must have out-degree 2 by alternation. But the only such graph is $\mathcal{B}_k$ itself. □

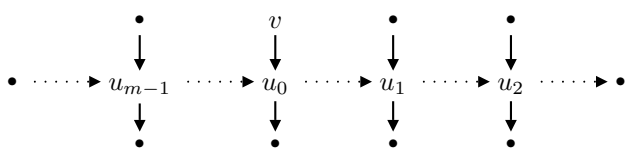
It follows that every word appears infinitely often on U, and we can define τ_i^w, $i \ge 0$, to be the position of the ith occurrence of word w in U. As always, this is interpreted to mean the position of the last bit of w. Define τ_i^k to be $\tau_i^{U_k}$, so $\tau_0^k = k$ and $\tau_1^k = \tau_k$. Also note that $\tau_{k+1} = \tau_2^k + 1$.

Proposition 4. *Any word of length k other than U_k appears exactly once as a match. The initial segment U_k appears exactly twice. Hence, the total number of matches of length k is $2^k + 1$.*

Proof. First suppose $u \in \mathbf{2}^k$ is not an initial segment of U. By lemma 1 $a\,u$ and $\overline{a}\,u$ both appear in U. The first such occurrences will have u as match. Clearly, from then on u cannot appear again as a match. Likewise, by 1 any initial segment $u = U_k$ must occur twice as a match since there are occurrences u, $a\,u$ and $\overline{a}\,u$. As before, u cannot reappear as a match later on in the sequence. □

2.2 Rounds and Irregular Words

Proposition 3 suggests that the construction of U can be naturally decomposed into a sequence of of rounds during which Λ remains constant. We will refer to the interval $R_k = [\tau_k, \tau_{k+1} - 1]$ as the k *principal round*. During R_k, the maximum match function Λ is equal to k, but λ may well drop below k. Up to time $t = \tau_{k+1} - 1$ the EM sequence traces two cycles C_0 and C_1 in $\mathcal{B}_k$, both anchored at $u = U_k$. C_0 is a simple cycle, and the two cycles are edge-disjoint. Note that the complement $\overline{\mathcal{B}}_k(t) = \mathcal{B}_k - C_0 - C_1$ consists only of degree 2 and, possibly, degree 4 points, the latter corresponding to words of length k not yet encountered at time t. The strongly connected components are thus all Eulerian.

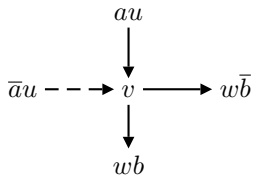


When U later touches one of these components at u_0, by necessity a degree 2 point, we have the following situation: $v = aw$ and $u_0 = wb$ so that the sequence look like $\ldots a\,w\,b \ldots a\,w\,\bar{b} \ldots$ Thus, the first two occurrences of w are preceded by the same bit. Such words will be called *irregular* and we will see shortly that the first three occurrences of any irregular word are of the form $\ldots a\,w\,b \ldots a\,w\,\bar{b} \ldots \bar{a}\,w\,b \ldots$ For the sake of completeness, we distinguish between irregular, regular and initial words. It is easy to see that all words 0^k and 1^k, $k \geq 2$ are irregular. There seem to be few irregular words; for example, there are only 12 irregular words of length 10. It is clear from the definitions that whenever v occurs as a match, all its prefixes must already have occurred as matches. Because of irregular words, the situation for suffixes is slightly more complicated, but we will see that they too occur as matches with a slight delay.

Our interest in irregular words stems from the fact that they are closely connected with changes in match length. Within any principal round, λ can decrease only when an irregular word is encountered for the second time, and will then correspondingly increase when the same word is encountered for the third time, at which point it appears as a match. First, increases in match length.

Lemma 2. *Suppose the match length increases at time t, i.e., $\lambda(t+1) = \lambda(t)+1$, but Λ does not increase at time t. Then $v = \mu(t)$ is irregular and $t = \tau_2^v$. Moreover, at time $s = \tau_1^v$ the match length decreases: $\lambda(s) > \lambda(s+1)$.*

Proof. Set $k = |v|$ and consider the edges incident upon v in $\mathcal{B}_k$ at time t. The dashed edge indicates the last step.



Since the match length increases, both edges (v, wb) and $(v, w\bar{b})$ must already lie on U_t. But that means that the edge (au, v) must appear at least twice on U_t, and v is irregular. Now consider the time $s = \tau_1^v$ of the second appearance. We must have $s > r = \tau_2^k$. But the strongly connected component of v in the residual graph $\overline{\mathcal{B}}_k(r)$ consists only of degree 2 and, possibly, degree 4 points; point v itself is in particular degree 2. As a consequence, U must then trace a closed path in this component that ends at v at time $t = \tau_2^v$. Lastly, the match length at time $s+1$ is k, but must have been larger than k at time s. □

Thus all changes in match length inside of a principal round are associated with irregular words. The lemma suggests the following definition. A *minor round (of order k)* is a pair (r, s) of natural numbers, $r \leq s$, with the property that $\lambda(r-1) \geq k+1$, $\lambda(t) \leq k$ for all t, $r \leq t \leq s$, and $\lambda(s+1) \geq k+1$. Since trivially $\lambda(t+1) \leq \lambda(t)+1$, the last condition is equivalent to $\lambda(s+1) = k+1$.

Note that minor rounds are either disjoint or nested. Moreover, any minor round that starts during a principal round must be contained in that principal

round. We can now show that match length never drops by more than 1 at a time.

Lemma 3. *Let (r, s) be a minor round. Then $\lambda(r-1) = \lambda(r) + 1 = \lambda(s+1)$.*

Proof. From the definition, for any minor round (r, s) we have $\lambda(s+1) - \lambda(r-1) \leq 0$. Now consider the principal round for k. As we have seen, all minor rounds starting before R_k are already finished at time τ_1^k. But if any of the minor rounds during the k principal round had $\lambda(s+1) - \lambda(r-1) < 0$ the match length at the end of R_k would be less than k, contradicting the fact that the match length increases to $k+1$ at the beginning of the next principal round. □

Hence, there cannot be gaps between two consecutive match length values.

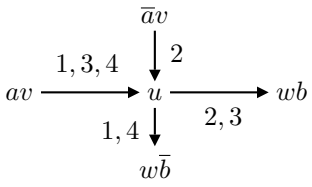
Theorem 1. *No-Gap*
For all n, $\lambda(n) - 1 \leq \lambda(n+1) \leq \lambda(n) + 1$.

2.3 A Lower Bound

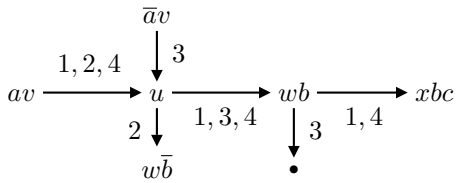
It follows from the last section that for u not an initial segment, $\tau_1^u \in R_k$ implies that u matches at some time $t \in R_k$. We will say that *u matches with delay* at time τ_1^u.

Lemma 4. *Let u be a word, not an initial segment. At time τ_3^u both $0u$ and $1u$ match with delay.*

Proof. First suppose that u is regular. Consider the neighborhood of u in $\mathcal{B}_k$ where $k = |u|$. In the following figure, the edge labels indicate one way U may have passed through u by time τ_3^u. Note that our claim follows trivially if both au and $\overline{a}u$ appear twice on $U_{\tau_3^u}$, so we only need to deal with the asymmetric case.



Since $u\overline{b}$ appears twice, it must match, with delay. But then Both $\overline{a}u\overline{b}$ and $au\overline{b}$ must appear, so $\overline{a}u$ appears twice and must match, with delay. A similar argument covers the remaining case. For u irregular the second encounter entails a third as indicated in the following figure. It suffices to deal with a fourth hit as indicated below.



But then ubc is also irregular, and we must have an occurrence of $\overline{a}ubc$, with delay. □

Lemma 5. *If uab has matched at time t, then both $0u$ and $1u$ match at time t, with delay.*

Proof. From the last lemma, our claim is obvious as long as u is not an initial segment. So suppose $u = U_k$ and consider the first 5 occurrences of u:

$$uabc \dots xu\overline{a} \dots \overline{x}ua\overline{b} \dots zuab\overline{c} \dots \overline{z}uabc$$

Note that the second occurrence of $\overline{x}uab$ is before the end of round R_{k+2}, so both xu and $\overline{x}u$ must have matched before the end of that round. □

Corollary 1. *If a word u of length k matches at time t, then all words of length at most $\lfloor k/2 \rfloor$ have matched at time t, with delay.*

From the corollary we obtain the lower bound $\tau_k = \Omega(\sqrt{2}^k)$. It follows from an argument in [8] that this yields a lower bound of 0.11 for the asymptotic density of U, a far cry from the observed value of 1/2.

3 Density and Near Monotonicity

The density of a set $W \subseteq \mathbf{2}^k$ is defined by $\Delta(W) = \frac{1}{|W|} \sum_{x \in W} \Delta(x)$. To keep notation simple, we adopt the convention that a less-than or less-than-or-equal sign in an expression indicates summation or union. E.g., we write $\binom{k}{<p}$ for $\sum_{0 \le i < p} \binom{k}{i}$. We denote $\mathbf{2}^{k,p}$ the set of words in $\mathbf{2}^k$ of density p/k, i.e., all words containing exactly p many 1's. Thus, $\left|\mathbf{2}^{k,p}\right| = \binom{k}{p}$. Clearly $\Delta(\mathbf{2}^k) = 1/2$ by symmetry. A simple computation shows that, perhaps somewhat counterintuitively, $\Delta(\mathbf{2}^{k,\le k/2}) = 1/2$. Hence, by monotonicity $\Delta(\mathbf{2}^{k,\le \varepsilon k}) = 1/2$ for all $1/2 \le \varepsilon \le 1$.

Now suppose $W \subseteq \mathbf{2}^k$ is a set of cardinality m. What is the least possible density of W? Clearly, a minimal density set W must have to form $\mathbf{2}^{k,\le p} \cup A$ where $A \subseteq 2^{k,p+1}$. If m forces $p \ge k/2$, then asymptotically the density of W is 1/2. Indeed, we will see that $m = \Omega(2^k)$ suffices. Let $0 \le p \le k$. From the definition of density we have

$$\Delta(\mathbf{2}^{k,\le p}) = \frac{\sum_{i \le p} \binom{k}{i} i/k}{\binom{k}{\le p}} = 1/2 - \left(4 \frac{\binom{k-1}{<p}}{\binom{k-1}{p}} + 2\right)^{-1}$$

Let $p = \lfloor \varepsilon k \rfloor + c$ where $c \in \mathbb{Z}$ is constant. As long as $1/2 \le \varepsilon \le 1$ we obtain density 1/2 in the limit. However, this is far as one can go.

Lemma 6. *Let $0 \le \varepsilon < 1/2$ and $p = \lfloor \varepsilon k \rfloor + c$ where $c \in \mathbb{Z}$ is constant. Then $\lim_{k \to \infty} \frac{\binom{k}{<p}}{\binom{k}{p}} = \varepsilon/(1-2\varepsilon)$.*

Proof. For the sake of brevity we write $\gamma = \frac{\binom{k}{<p}}{\binom{k}{p}}$. First note that the density of $\mathbf{2}^{k,\le \varepsilon k}$ is clearly bounded from above by ε. Since $\Delta(\mathbf{2}^{k,\le \varepsilon k}) = \frac{\gamma}{2\gamma+1}$ it follows

that $\gamma \leq \frac{\varepsilon}{1-2\varepsilon}$. For the opposite direction we rewrite the individual quotients of binomial coefficients in terms of Pochhammer symbols as $\binom{k}{p-i}/\binom{k}{p} = \frac{(p-i+1)_i}{(k-p+1)_i}$ Hence the limit of $\binom{k}{p-i}/\binom{k}{p}$ as k goes to infinity is $\left(\frac{\varepsilon}{1-\varepsilon}\right)^i$. Now consider a partial sum $\sum_{i=1}^{n} \binom{k}{p-i}/\binom{k}{p} \leq \gamma$ where n is fixed. Then

$$\sum_{i=1}^{n} \frac{\binom{k}{p-i}}{\binom{k}{p}} \quad \longrightarrow \quad \sum_{i=1}^{n} \left(\frac{\varepsilon}{1-\varepsilon}\right)^i = \frac{\varepsilon}{1-2\varepsilon}\left(1 - \left(\frac{\varepsilon}{1-\varepsilon}\right)^n\right)$$

as k goes to infinity. But then $\lim_{k\to\infty} \gamma \geq \frac{\varepsilon}{1-2\varepsilon}$. Thus, in the limit $\gamma = \frac{\varepsilon}{1-2\varepsilon}$. □

Corollary 2. *Let $0 \leq \delta \leq 1/2$. Then $\lim_{k\to\infty} \Delta(\mathbf{2}^{k,\leq \delta k}) = \delta$.*

The definition of density extends naturally to multisets $A, B \subseteq \mathbf{2}^k$ via $\Delta(A+B) = \frac{|A|\Delta(A)+|B|\Delta(B)}{|A+B|}$. Assuming near monotonicity, we can now establish balance of U by calculating the limiting density at times τ_k. Let us say that λ is c-monotonic if $\forall\, t, s\, (\lambda(t+s) \geq \lambda(t) - c)$. Thus, it seems that λ is 2-monotonic, but the argument below works for any constant c.

Theorem 2. *If λ is c-monotonic for some constant c, then the Ehrenfeucht-Mycielski sequence is balanced.*

Proof. Assume otherwise; by symmetry we only have to consider the case where for infinitely many t we have $\Delta(U_t) < \delta_0 < 1/2$. Let $\tau_{k+c} \leq t < \tau_{k+c+1}$ and consider the multiset $W = \mathsf{cov}_k(U_t)$. For t sufficiently large $\Delta(W) < \delta_0$. Since all matches after t have length at least k by our assumption, certainly $\mathbf{2}^k \subseteq W$. Since all words of length $k+c+1$ on U_t are unique, there is a constant bounding the multiplicities of $x \in \mathbf{2}^k$ in W and we can write $W = \mathbf{2}^k + V$ where $\forall\, x \in \mathbf{2}^k\, (V(x) \leq d)$. Let $\delta = \Delta(V)$ and $m = |V|$, so that

$$\delta_0 > \Delta(W) = \frac{2^k \cdot 1/2 + m \cdot \delta}{2^k + m}.$$

It follows that $2^{k-1}(1-2\delta_0) \leq m(\delta_0 - \delta) \leq m$ so that $m = \Omega(2^k)$.

On the other hand, we must have $\delta_0 \geq \Delta(V) \geq \Delta(d \cdot \mathbf{2}^{k,\leq p}) = \Delta(\mathbf{2}^{k,\leq p})$. To see this, note that if for some $x \in \mathbf{2}^k$, $q/k = \Delta(x) < \Delta(\mathbf{2}^k + d \cdot \mathbf{2}^{k,<q})$ then $\mathbf{2}^k + d \cdot \mathbf{2}^{k,\leq q}$ minimizes the density of all multisets with multiplicities bounded by d that include x. From the last corollary we get $p \leq \delta_0 k$. Using Sterling approximation we see that the cardinality m is bounded by $d\binom{k}{\leq \delta_0 k} \leq d + d\delta_0 k \binom{k}{\delta_0 k} \approx d + d\sqrt{\frac{\delta_0 k}{2\pi(1-\delta_0)}}\, 2^{kH(\delta_0)}$ where $H(x) = -x \lg x - (1-x)\lg(1-x)$ is the binary entropy function over the interval $[0,1]$. It is well-known that H is symmetric about $x = 1/2$ and concave, with maximum $H(1/2) = 1$. Hence $2^{H(\delta_0)} < 2$, contradicting our previous lower bound. Hence, the density of W approaches $1/2$, as required. □

4 Conclusion

We have established some regularity properties of the Ehrenfeucht-Mycielski sequence, notably the No-Gap conjecture and a weaker form of Near Monotonicity. A better analysis of the match length function should show that λ is in fact 2-monotonic. Specifically, a study of the de Bruijn graphs $\overline{\mathcal{B}}_k$ in `automata` indicates that the strongly connected component of this graph have special properties that could be exploited to establish this claim. Alas, we are currently unable give a complete proof. The construction of the Ehrenfeucht-Mycielski sequence easily generalizes to arbitrary prefixes: start with a word w, and then attach new bits at the end according to the same rules as for the standard sequence. It seems that all results and conjectures here seem to carry over, mutatis mutandis, to these generalized Ehrenfeucht-Mycielski sequences. In particular, they all appear to have limiting density 1/2.

Source code and Mathematica notebooks used in the writing of this paper can be found at `www.cs.cmu/~sutner`.

Resumo

Dando jus à matemática experimental, mostramos como o Maple pode ser usado na investigação matemática de algumas questões actualmente sem resposta na Teoria dos Números. A tese defendida é que os alunos de um curso de Matemática podem facilmente usar o computador como um lugar onde se excita e exercita a imaginação.

1 Introdução

Albert Einstein é conhecido por ter dito que "a imaginação é mais importante que o conhecimento". Se assim é, porquê esperar pelo mestrado ou doutoramento para começar a enfrentar problemas em aberto? Não é a criatividade prerrogativa dos mais novos? Em [3] mostrei como com muito pouco conhecimento é possível debruçar-mo-nos sobre algumas questões actualmente sem resposta na Teoria de Computação. Aqui, e a propósito do ano 2003 ter sido escolhido pela APM como o ano da *Matemática e Tecnologia*, vou procurar mostrar como o computador e um ambiente moderno de computação algébrica, como seja o Maple, podem ser excelentes auxiliares na abordagem a "quebra-cabeças" que a matemática dos números actualmente nos coloca. A minha escolha do sistema Maple prende-se com o facto de ser este o programa informático actualmente usado na cadeira de *Computadores no Ensino da Matemática*, no Departamento de Matemática da Universidade de Aveiro. Desta maneira os meus alunos serão prova viva de que basta um semestre de "tecnologias na educação matemática", para nos podermos aventurar por "mares ainda não navegados". O leitor que queira aprender sobre o Maple poderá começar por consultar o nosso site de *Computadores no Ensino da Matemática*: `http://webct.ua.pt/public/compensmat/index.html`.

2 Números felizes

Seja $n \in \mathbb{N}$ um número natural com representação decimal $n = d_k \ldots d_0$, $0 \leq d_i \leq 9$ $(i = 0, \ldots, k)$, e denotemos por $\sigma(n)$ a soma dos quadrados dos dígitos decimais de n: $\sigma(n) = \sum_{i=0}^{k} (d_i)^2$. Dizemos que n é um *número feliz* se existir um $r \in \mathbb{N}$ tal que $\underbrace{(\sigma \circ \cdots \circ \sigma)}_{r \text{ vezes}}(n) = 1$. Por exemplo, 7 é um número feliz ($r = 5$),

$$\sigma(7) = 49,\ \sigma(49) = 97,\ \sigma(97) = 130,\ \sigma(130) = 10,\ \sigma(10) = 1\,;$$

enquanto 2 não:

$$\sigma(2) = 4,\ \sigma(4) = 16,\ \sigma(16) = 37,\ \sigma(37) = 58,\ \sigma(58) = 89,$$
$$\sigma(89) = 145,\ \sigma(145) = 42,\ \sigma(42) = 20,\ \sigma(20) = 4\ \ldots$$

Vamos definir em Maple a função característica Booleana dos números felizes. Começamos por definir a função `digitos` que nos devolve a sequência de dígitos de uma dado número n

```
> digitos := n -> seq(iquo(irem(n,10^i),10^(i-1)),i=1..length(n)):
> digitos(12345);
```

$$5, 4, 3, 2, 1$$

A função σ é agora facilmente construída

```
> sigma := n -> add(i^2,i=digitos(n)):
> sigma(24);
```

$$20$$

O processo de composição da função σ é obtido usando o operador @ do Maple:

```
> s := (n,r) -> seq((sigma@@i)(n),i=1..r):
> s(7,5);
```

$$49,\ 97,\ 130,\ 10,\ 1$$

```
> s(2,9);
```

$$4,\ 16,\ 37,\ 58,\ 89,\ 145,\ 42,\ 20,\ 4$$

Para automatizarmos o processo de decisão se um número é feliz ou não, recorremos a alguma programação. O seguinte procedimento deve ser claro.

```
> feliz := proc(n)
>   local L, v:
>   L := {}:
>   v := sigma(n):
>   while (not (member(v,L) or v=1)) do
>     L := L union {v}:
>     v := sigma(v):
>   end do:
>   if (v = 1) then true else false end if:
> end proc:
```

Podemos agora questionar o sistema Maple acerca da felicidade de um determinado número.

```
> feliz(7);
```

$$true$$

```
> feliz(2);
```

$$false$$

A lista de todos os números felizes até 100 é dada por

```
> select(feliz,[$1..100]);
```

$$[1, 7, 10, 13, 19, 23, 28, 31, 32, 44, 49, 68, 70, 79, 82, 86, 91, 94, 97, 100]$$

Concluímos então que existem 20 números felizes de entre os primeiros 100 naturais

```
> nops(select(feliz,[$1..100]));
```

$$20$$

Existem 143 números felizes não superiores a 1000; 1442 não superiores a 10000; e 3038 não superiores a 20000:

```
> nops(select(feliz,[$1..1000]));
```

$$143$$

```
> nops(select(feliz,[$1..10000]));
```

$$1442$$

```
> nops(select(feliz,[$1..20000]));
```

$$3038$$

Estas últimas experiências com o Maple permitem-nos formular a seguinte conjectura.

Conjectura 1. *Cerca de um sétimo de todos os números são felizes.*

Uma questão interessante é estudar números felizes consecutivos. De entre os primeiros 1442 números felizes podemos encontrar 238 pares de números felizes consecutivos (o mais pequeno é o $(31, 32)$);

```
> felizDezMil := select(feliz,[$1..10000]):
> nops(select(i->member(i,felizDezMil) and
                  member(i+1,felizDezMil),felizDezMil));
```

$$238$$

onze ternos de números felizes consecutivos, o mais pequeno dos quais é o $(1880, 1881, 1882)$;

```
> select(i->member(i,felizDezMil)   and
             member(i+1,felizDezMil) and
             member(i+2,felizDezMil),felizDezMil);
```

$$[1880, 4780, 4870, 7480, 7839, 7840, 8180, 8470, 8739, 8740, 8810]$$

dois quaternos de números felizes consecutivos, o mais pequeno dos quais é o $(7839, 7840, 7841, 7842)$;

```
> select(i->member(i,felizDezMil)   and
             member(i+1,felizDezMil) and
             member(i+2,felizDezMil) and
             member(i+3,felizDezMil),felizDezMil);
```

$$[7839, 8739]$$

e nenhuma sequência de cinco números felizes consecutivos.

```
> select(i->member(i,felizDezMil)   and
             member(i+1,felizDezMil) and
             member(i+2,felizDezMil) and
             member(i+3,felizDezMil) and
             member(i+4,felizDezMil),felizDezMil);
```

[ ]

Sabe-se que a primeira sequência de cinco números felizes consecutivos começa com o 44488.

```
feliz(44488) and feliz(44489) and feliz(44490) and
                feliz(44491) and feliz(44492);
```

$$true$$

É também conhecida uma sequência de 7 números felizes consecutivos, que começa com o número 7899999999999959999999996 (*vide* [4]).

3 Sucessões de Smarandache

Dada uma sucessão de inteiros $\{u_n\}$, a correspondente sucessão de Smarandache $\{s_n\}$ é definida por concatenação de inteiros como se segue:

$$s_1 = u_1,\ s_2 = u_1u_2,\ \ldots,\ s_n = u_1 \cdots u_n,\ \ldots$$

Estamos interessados na sucessão de Smarandache associada aos números felizes. Os primeiros elementos desta sucessão são:

$$1, 17, 1710, 171013, 17101319, 1710131923, 171013192328, 17101319232831, \ldots$$

Começamos por implementar a concatenação de inteiros em Maple.

```
> conc := (a,b) -> a*10^length(b)+b:
> conc(12,345);
```

$$12345$$

Formando a lista dos números felizes até um certo n, e usando a função `conc` acima definida, a correspondente sucessão de Smarandache é facilmente obtida.

```
> sh := proc(n)
>   local L, R, i:
>   L := select(feliz,[$1..n]):
>   R := array(1..nops(L),L):
>   for i from 2 by 1 while i <= nops(L) do
>     R[i]:=conc(R[i-1],L[i]):
>   end do:
>   return(R):
> end proc:
```

Como

```
> select(feliz,[$1..31]);
```

$$[1, 7, 10, 13, 19, 23, 28, 31]$$

os primeiros 8 valores da sucessão de Smarandache são então

```
> print(sh(31));
```

$$[1, 17, 1710, 171013, 17101319, 1710131923, 171013192328, 17101319232831]$$

Existem muitas questões em aberto associadas à sucessão de Smarandache dos números felizes (*vide* [2]). Umas dizem respeito à existência de números primos na sucessão; outras à existência de números felizes. Façamos agora alguma investigação a este respeito. Usando o Maple é fácil concluir que de entre os primeiros 143 termos da sucessão de Smarandache dos números felizes, apenas 3 são primos.

```
> primos := select(isprime,sh(1000)):
> nops([seq(primos[i],i=1..143)]);
```

3

Se fizermos `print(primos)` vemos que os três primos são $s_2 = 17$, $s_5 = 17101319$ e s_{43} (s_{43} é um primo com 108 dígitos decimais).

```
> primos[2], primos[5];
```

17, 17101319

```
> length(primos[43]);
```

108

Apenas são conhecidos estes números primos na sucessão de Smarandache dos números felizes. Permanece por esclarecer se eles serão ou não em número finito (*vide* [1]).

Existem 31 números felizes de entre os primeiros 143 termos da sucessão de Smarandache dos números felizes:

```
> shFelizes := select(feliz,sh(1000)):
> nops([seq(shFelizes[i],i=1..143)]);
```

31

Recorrendo ao comando `print(shFelizes)` vemos que esses números são o s_1, s_{11}, s_{14}, s_{30}, s_{31}, s_{35}, s_{48}, s_{52}, s_{58}, s_{62}, s_{67}, s_{69}, s_{71}, s_{76}, s_{77}, s_{78}, s_{82}, s_{83}, s_{85}, s_{98}, s_{104}, s_{108}, s_{110}, s_{114}, s_{115}, s_{117}, s_{118}, s_{119}, s_{122}, s_{139} e s_{140}. A título de curiosidade, s_{140} tem 399 dígitos:

```
> length(shFelizes[140]);
```

399

Muito existe por esclarecer relativamente à existência de números felizes consecutivos na sucessão de Smarandache dos números felizes. Olhando para os resultados anteriores vemos que o par mais pequeno de números felizes consecutivos é o (s_{30}, s_{31}); enquanto o terno mais pequeno é o (s_{76}, s_{77}, s_{78}). Quantos termos consecutivos são possíveis? É capaz de encontrar exemplos, digamos, de seis números felizes consecutivos? Estas e outras questões estão em aberto (*vide* [1]). Ferramentas como o Maple são boas auxiliares neste tipo de investigações. Fico à espera de algumas respostas da sua parte.

A. Nová evropská iniciativa v oblasti kryptografie

Ing. Jaroslav Pinkava, CSc. (AEC, spol. s r.o.)

V druhé polovině května se objevila na webu informace o nové aktivitě v rámci Evropské Unie. Jedná se o projekt NESSIE (New European Schemes for Signature, Integrity, and Encryption) programu IST Evropské komise (http://cryptonessie.org).

NESSIE je tříletý projekt, který byl zahájen 1.ledna 2000. Jeho hlavním cílem je přinést celé „portfolio“ bezpečných kryptografických modelů (tzv. „kryptografických primitivů“), které lze pak používat v rámci různých technologických platforem. Jednotlivé modely budou vytvářeny na základě veřejných návrhů a rovněž tak vyhodnocení těchto návrhů proběhne otevřenou a transparentní cestou. Celková koncepce tohoto portfolia je podstatně širší než obdobný projekt AES (Advanced Encryption Standard), který řídí americký NIST. Projekt zároveň navazuje na již získané výsledky v rámci evropských struktur. Zde lze zmínit např. Směrnici Evropské Unie pro elektronický podpis nebo čerstvě vydanou (květen 2000) normu k formátům elektronických podpisů – Electronic Signature Formats, ETSI 201 733.

Celkem se jedná o následujících deset tříd kryptografických primitivů:

1. Blokové šifry
2. Synchronní proudové šifry
3. Samosynchronizující se proudové šifry
4. Autentizační kódy zpráv (MAC)
5. Hashovací funkce rezistantní vůči kolizím
6. Jednosměrné hashovací funkce
7. Pseudonáhodné funkce
8. Asymetrická schémata pro šifrování
9. Asymetrická schémata pro digitální podpis
10. Asymetrická schémata pro identifikaci

V rámci každé třídy budou existovat dvě bezpečnostní úrovně (normální a vysoká), s výjimkou blokových šifer, kde bude ještě třetí úroveň (historická-normální). Tj. například blokové šifry vysoké bezpečnostní úrovně mají pracovat s bloky textu v délce 128 bitů a s klíčem nejméně v délce 256 bitů. Blokové šifry normální bezpečnostní úrovně pracují rovněž s bloky otevřeného textu v délce 128 bitů a musí mít klíč dlouhý nejméně 128 bitů. Zmíněná třetí úroveň ponechává možnost existence blokových šifer, které pracují s bloky otevřeného textu v délce 64 bitů (jako je tomu u většiny současných algoritmů). Délka klíče i u této třetí úrovně však musí být minimálně 128 bitů.

Vyhodnocení jednotlivých návrhů bude probíhat na základě:

a) bezpečnostních kriterií (obtížnost útoků, zdůvodnění bezpečnosti,...)
b) implementačních kriterií (software, hardware, nároky na objem paměti, spolehlivost,...)
c) dalších kriterií, jako je jednoduchost a zřejmost návrhu atd.

V rámci prvního kola, které končí v září 2000, mají být odevzdány výchozí návrhy. V říjnu pak bude následovat jejich první projednání v rámci první „lochneské“ konference.

Jedním ze základních cílů projektu je také posílit pozice evropského kryptografického průmyslu v návaznosti na výsledky evropského výzkumu. Nesporné jsou význačné dopady na celou kryptografickou praxi.

B. Fermatův test primality, Carmichelova čísla, bezčtvercová čísla

Mgr. Pavel Vondruška (NBÚ)

Část I.

Současné moderní kryptosystémy s veřejným klíčem se opírají o řadu výsledků z teorie čísel. Mimo teoretického studia, které je nezbytné z hlediska zdůvodnění samotného principu bezpečnosti a odolnosti systémů, je zde i řada praktických problémů. Příkladem může být potřeba rychle vygenerovat velká prvočísla. Zpravidla k tomu slouží pravděpodobnostní testy jako např. Solovay-Strassenův test, Lehmannův test, Rabin-Millerův test a Fermatův test. Kromě pravděpodobnostních algoritmů k testování prvočíselnosti existují i postupy, které umožňují poněkud více. V případě, že p je skutečně prvočíslo, pak existují algoritmy, které toto dokáží. Toto umožňuje Cohen-Lenstrův test a Atkin-Morainův test. Z důvodu rychlosti se však v praxi používají pouze pravděpodobnostní testy a velké prvočíslo se vygeneruje pouze s předem zvolenou , dostatečnou pravděpodobností. Pro svoji jednoduchost se také stále ještě implementuje Fermatův test primality.

Fermatův test primality

Tento test je založen na platnosti tzv. Malé Fermatovy věty.
Jestliže p je prvočíslo a číslo a je libovolné přirozené číslo menší jak p, pak $a^p \equiv a \bmod p$.

O platnosti tohoto tvrzení se zmiňuje poprvé Fermat 18.10.1640 ve svém dopise Freniclovi. Pro přesnost uveďme, že uvádí jinou – ekvivalentní formulaci :

Je-li p prvočíslo, pak p dělí $a^{p-1} - 1$ pro všechna a, která nejsou dělitelná p.

Jak lze využít tuto větu pro generování prvočísel ?

Máme dané n > 1, zvolíme a > 1 a spočteme pak $a^{n-1} \bmod n$. Pokud výsledek je různý od jedné, pak n není prvočíslo. Pokud však výsledek je roven jedné, pak to ještě neznamená, že n je prvočíslo. Vezmeme jiné číslo a provedeme celý test znovu.

Pokud by někdo tento test programoval, doporučujeme pro volbu n použít známé technické finty :

- vygenerujeme dostatečně velké číslo (např. 1024 bitů)
- bity nejvyššího a nejnižšího řádu musí být jednička (jednička na nejvyšším řádu zaručí, že číslo má požadovanou délku, 1 na nejnižším řádu, že číslo je liché)
- prověříme, že číslo n není dělitelné malými prvočísly : 3,5,7,11, …, 251

Nyní provedeme výše popsaný Fermatův test s náhodně zvoleným a. Jestliže n splní podmínku testu ($a^{n-1} = 1 \bmod n$), vygenerujeme jiné náhodné číslo a a s ním test zopakujeme. Toto provádíme opakovaně, podle vyžadované přesnosti..

Takto získané číslo n prohlásíme za prvočíslo.

Je zřejmé, že zvyšujeme-li počet voleb čísla a, zvyšuje se pravděpodobnost, že námi vygenerované číslo n je prvočíslo.

Ukázalo se však, že existují taková n (která nejsou prvočísly), pro která Fermatův test je splněn při libovolné volbě a. Tato složená čísla se nazývají **Carmichaelova čísla**.

Carmichaelova čísla

Číslo n nazveme Carmichaelovo číslo, pokud splňuje malou Fermatovu větu pro libovolnou volbu báze a . Tedy $a^{n-1} - 1 \equiv 0 \pmod{n}$ pro každou volbu $1 < a < n$.

Tato čísla se někdy nazývají absolutní pseudoprvočísla. Nazývají se podle R.D.Carmichaela, který o jejich existenci napsal prvou práci. Bylo to v roce 1910 a sám Carmichael spočítal 15 příkladů takových čísel. Předpověděl, že jich je nekonečně mnoho.

Postupně byla nalezena všechna Carmichaelova čísla menší než 100 000. Jsou to tato čísla:
561, 1105, 1729, 2465, 2821, 6601, 8911, 10585, 15841, 29341, 41041, 46657, 52633, 62745, 63973 a 75361 .

V roce 1939 Chernik zjistil, že pokud čísla p = 6m+1, q=12m+1 a r=18m +1 jsou prvočísla, tak číslo pqr je Carmichaelovo prvočíslo. Důkaz je velice jednoduchý :

$N \equiv (6m+1)*(12m+1)*(18m+1) = 1296m^3 + 396m^2 + 36m + 1$
N-1 je násobek 36m a dále je zřejmě 36m nejmenší společný násobek 6m, 12m, 18m
$a^{N-1} \equiv 1 \pmod{}$ pro každé z prvočísel 6m+1, 12m+1 a 8m +1
a tedy $a^{N-1} \equiv 1 \pmod{((6m+1)*(12m+1)*(8m+1))}$

Pomocí tohoto postupu byla nalezena některá Carmichaelova čísla tohoto speciálního tvaru.
Carmichaelova čísla tak lze získat pro m=1, 6, 35, 45, 51, 55, 56, …
Odpovídající čísla potom jsou : 1729, 294409, 56052361, 118901521, …
V lednu 1999 bylo takto získáno největší známé Carmichaelovo číslo a to pro hodnotu m= $133752260*3003*10^{1604}$. Faktory tohoto čísla N mají 1616, 1616 a 1617 cifer.

Studiu těchto čísel se věnovali i další matematici. Uveďme alespoň ty nejdůležitější: Erdos (1956), Alford (1994), Hoffman (1998) a Pinch a Dubner (1989-1998).

Z jejich výsledků vyplynulo, že Carmichaelových čísel je skutečně nekonečně mnoho a že neexistuje rozklad žádného Carmichaelova čísla na dva činitele.

Nejmenší Carmichaelovo číslo, které má rozklad na :
3 činitele je : 561 = 3*11*17 .
4 činitele je : 41041 = 7*11*13*41
5 činitelů je : 825265 = 5*7*17*19*73
6 činitelů je : 321197185 =5*19*23*29*37*137

Dosud největší známá Carmichaelova čísla, která mají rozklad na :

3 činitele je číslo s	:	10 200 ciframi
4 činitele je číslo s	:	2 467 ciframi
5 činitelů je číslo s	:	1 015 ciframi
6 činitelů je číslo s	:	827 ciframi

Richard Pinch (1993) uvádí úplný seznam všech Carmichaelových čísel menších než 10^{16}.
Odtud vyplývá, že Carmichaelových čísel menších než

10^6	je	43
10^{10}	je	2 163
10^{15}	je	105 212
10^{16}	je	246 683

V roce 1994 Alford odvodil odhad pro počet Carmichaelových čísel C(n).
Pro dostatečně velká n (řádově $n \approx 10^7$) platí : $C(n) \approx n^{2/7}$.

Závěrem uvedeme, že Carmichaelova čísla mají následující vlastnosti :

1. Jestliž p je prvočíslo, které dělí Carmichaelovo číslo n, potom z $n \equiv 1 \pmod{p-1}$ plyne , že $n \equiv p \pmod{p(p-1)}$.
2. Každé Carmichaelovo číslo je bezčtvercové.
3. Liché složené bezčtvercové číslo n je Carmichaelovo číslo právě tehdy když n dělí jmenovatele Bernoulliho čísla B_{n-1}

Z teoretického hlediska je nejzajímavější druhá vlastnost. Příště si řekneme, co vlastně bezčtvercová čísla jsou a jaký je jejich význam v teorii čísel a pro kryptologii.

C. Červ LOVE-LETTER-FOR-YOU.TXT.VBS

Mgr. Pavel Vondruška, NBÚ

Worm (červ) I_LOVE_YOU (LoveLetter) se stal opravdovým mediálním hitem tohoto jara. Objevil se 4.května a během několika málo hodin zasáhl celou Asii a Evropu a jen o málo hodin později i Ameriku. Love Letter je worm napsaný ve VBS (Visual Basic Script) . Šíří se v e-mailech, ke kterým se připojuje ve formě souboru LOVE-LETTER-FOR-YOU.TXT.VBS (kolem 10 KB). Subjekt "infikované" e-mailové zprávy zní: "ILOVEYOU". V těle zprávy je obsažen text: "kindly check the attached LOVELETTER coming from me.". "Dvojitá" přípona u souboru využívá toho, že v některých klientech není část za druhou tečkou viditelná. Příjemce si pak myslí, že je to obyčejný textový soubor (TXT) a s pocitem bezpečí a notnou dávkou zvědavosti jej otevře. Pro šíření potřebuje tento worm program MS Outlook - odtud se jednoduše sám rozešle na další e-mailové adresy, které najde v adresáři. Po spuštění souboru LOVE-LETTER-FOR-YOU.TXT.VBS se červ zabydlí v počítači (proto je to červ, nikoliv virus).

Vytvoří nové klíče v registrech:
HKLM\Software\Microsoft\Windows\CurrentVersion\Run\MSKernel32
HKLM\Software\Microsoft\Windows\CurrentVersion\RunServices\Win32DLL
V adresáři C:\WINDOWS\SYSTEM pak dále vytvoří soubory MSKERNEL32.VBS a Win32DLL.VBS. Na pevných i síťových discích vyhledává soubory s příponou VBS, VBE, JS, JSE, CSS, WSH, SCT, HTA, jejichž obsah přepíše svým tělem a příponu změní na VBS. V případě souborů s příponou JPG či JPEG je vytvořena "dvojitá" přípona - původní + .VBS. Se soubory s příponou MP2 a MP3 pracuje červ jinak - nejprve vytvoří kopie těchto souborů - ty pak následně přepíše vlastním tělem a vytvoří na nich "dvojitou" příponu (původní_název.MP3.VBS). Atribut těchto souborů je změněn na hidden. Pokud neexistuje soubor C:\WINDOWS\WINFAT32.EXE, nastaví domovskou stránku Internet Exploreru tak, aby ze serveru http://www.skyinet.net/~ stahoval soubor WIN-BUGSFIX.EXE. Tento soubor obsahuje trojského koně (program, o jehož činnosti vlastník PC nic neví). Po aktivaci se tento trojský kůň usadí právě do souboru WINFAT32.EXE a na adresu na Filipínách se snaží přes e-mail odesílat nakradená senzitivní data (uživatelské jméno, IP, hesla atd.). Tato adresa také samozřejmě pomohla odhalit a obvinit potenciálního pachatele.

Červ I_LOVE_YOU může následně dorazit na vaše PC i přes IRC. Pokud VBS: LoveLetter nalezne klienta mIRC, přepíše soubor „mirc.ini“ a pak je schopen poslat sám sebe ostatním uživatelům IRC.

Podle všeho se zdá, že autor nechtěl zahltit síť a ochromit provoz serverů prakticky na celém světě. Pravděpodobně pouze chtěl pomocí svého červa dopravit do počítačů trojského koně a pomocí něj získat hesla a tedy nadvládu nad cizími počítači. To mohl následně využít např. i ke svému obohacení (uzavírání e-obchodů apod.). Zřejmě netušil, že jeho útok využívající psychologii běžného uživatele e-mailové pošty bude mít takový „úspěch“.

Po originálním červu se velice rychle objevila řada variant a modifikací. „Autoři“ jednoduše originál lehce upravili a nová varianta byla na světě. Některé „varianty“ spočívaly pouze v přepsání textů a jmen, jiné byly důmyslnější. Psychologický nátlak na uživatele, který musí aktivně spolupracovat – otevřít přílohu, se měnil. Jedna varianta zasílá vtip, jiná varianta se tváří jako zpráva od Symantecu a zasílá údajné upozornění na LoveLetter. Nejzajímavější je ta, která oznamuje stažení 326 USD z kreditní karty a žádá o vytištění přiložené faktury. Variant tohoto červa se objevilo několik desítek.

LoveLetter představuje novou generaci nebezpečných programů. Rozšířil se velice rychle a napáchal obrovské škody. Využívá bezpečnostních děr v operačním systému a aplikacích a dále psychologický prvek, kterým donutil uživatele ke spolupráci. Již jsme se zmínili, že tím, že ve Windows nejsou implicitně známé přípony souborů zobrazovány, řada uživatelů příponu .vbs u wormu neviděla a otevírala jej v domnění, že se jedná o textový soubor. Dalšími problémy, které můžeme jmenovat, jsou : implicitní instalace Windows scripting Host, provázanost aplikací, příliš silný jazyk VBS, nemožnost oddělit nastavení bezpečnosti jinak pro Explorer a jinak pro poštovní klienty, implementace HTML a VBS do poštovních klientů, spouštění kódů (programy, skripty) přímo z poštovních klientů atd. Doufejme, řže výrobci a autoři aplikačních programů (a především Microsoft) zareagují velice rychle a potenciální bezpečnostní díry budou odstraněny. Obávám se však, že současný trend – maximální jednoduchost pro uživatele, absolutní provázanost aplikací, kompatibilita téměř na úrovni binárních dat, silné makrojazyky, rozšíření VBS atd., předpoklad, že uživatel je nejšťastnější, když může jenom „klikat“ myší a není nucen přemýšlet, může vést v budoucnu k ještě větším problémům … KLIK.

Zde měl být původně celý „zdrojový kód“ LOVE-LETTER-FOR-YOU.TXT.VBS , ale vzhledem k jeho délce (10 kb, cca 5 stran A4) a vzhledem k tomu, že by po malé modifikaci mohl vzniknout další virus :-) , jsem se rozhodl umístit jen začátek z tohoto kódu.

D. EUROCRYPT 2000

Mgr. Pavel Vondruška (NBÚ)

Mezinárodní konference EUROCRYPT 2000 se konala 14.5. až 18.5. v Bruggách (Belgie). Konferenci pořádala IACR (International Association for Cryptolgic Research) ve spolupráci s belgickou odbornou skupinou COSIC.

Konference se zúčastnilo celkem cca 440 expertů z celého světa. Zastoupeny byly všechny kontinenty, největší účast byla z USA, Belgie (pořádající stát), Francie,… . Z ČR se zúčastnilo devět odborníků.

Přítomna byla celá světová kryptologická špička. Z těch nejznámějších uvedu (v závorce výsledek nebo fakt, který nositele příslušného jména především proslavil) například: Shamir (RSA, Twinkle) , Rivest (RSA), Biham (diferenční kryptoanalýza), Zimmermann (PGP), Lenstra (faktorizace), van Oorschot (autor jedné z nejznámějších monografií o kryptografii), Diffie (krypotsystém Diffie-Helmann), McCurley (současný předseda IACR), Wagner (A5/1, slide-attack), Rabin (Rabinovo schéma) a desítky dalších.

Konference Eurocrypt je společně s konfererencí Crypto (pravidelně pořádané v Santa Barbaře - USA) nejvýznamnější akcí v oblasti kryptologie v kalendářním roce. Tomu také odpovídají přijaté příspěvky. Byly zde prezentovány nejdůležitější a nejvýznamnější výsledky v této oblasti v období od minulé konference, EUROCRYPT 1999, která se konala v Praze. V každé sekci tak vždy zazněly pečlivě vybrané referáty, které vybíral programový výbor z velkého množství došlých referátů. Jednotlivé směry a tedy příslušné členění bylo vybráno následovně (v závorce počet přednášek):

- Factoring and Discrete Logarithm (3)
- Cryptoanalysis I: Digital Signatures (4)
- Private Information Retrieval (2)
- Key Management Protocols (3)
- Thresold Cryptography and Digital Signatures (4)
- Public-Key Encryption (2)
- Quantum Cryptography (2)
- Multi-Party Compution and Information Theory (3)
- Cryptoanalysis II: Public-Key (3)
- Zero Knowledge (2)
- Symetric Cryptography (3)
- Boolean Functions and Hardware (3)
- Voting Schemes (2)
- Cryptoanalysis III: Stream Ciphers and Block Ciphers (2)

Program byl již tradičně doplněn o poster session (16 příspěvků) a rump session (18 příspěvků) a dále o dvě přednášky zvaných řečníků : Mike Walker a A.E.Sale .

Krátký obsah některých vybraných témat

Factorization of a 512-Bit RSA Modulus
Jednalo se o prezentaci mimořádně důležitého výsledku ze srpna loňského roku - faktorizace 512 bitového modulu RSA. Tedy modulu, který se v komerčních aplikacích stále ještě používá. Fakt a metoda je odborné veřejnosti známa - zde zazněl tento příspěvek jako první především proto, že IACR takto chtělo ocenit všechny ty, kteří přispěli k dosažení tohoto cíle ke kterému se v několika posledních letech směřovalo.

Lenstra,Shamir : **Analysis and Optimization of the TWINKLE Factoring Device**
Profesor Shamir upravil své optoelektronické zařízení, které bylo poprvé představeno na rump session loni v Praze. Zařízení produkuje data vhodná ke zpracování metodou NFS nikoliv QS jako prvá verze. Podařilo se zvýšit takt zařízení 10x. Teoreticky (spolupráce 80 000 PC a výroba 5000 zařízení TWINKLE) je možné touto metodou faktorizovat již 768 bitový modul RSA.

F.Grieu : **A Chosen Message Attack on the ISO/IEC 9796-1 Signature Scheme**
F.Grieu předvedl útok proti podpisovému standardu ISO/IEC 9796-1. Nejedná se jen o teoretickou slabinu, ale o prakticky proveditelný útok. Rozebírána byla např. možnost, kdy lze padělat podpis známé zprávy , pokud jsou k dispozici 3 zprávy se stejným veřejným exponentem. Postup není výpočetně složitý. Chyba je natolik závažná, že vyžaduje změnu tohoto standardu.

M.Girault aj.Misarsky - **Cryptanalysis of Contermeasures Proposed for Repairing ISO 9796-1**
Standard ISO 9796-1 (publikován v roce 1991) byl prvním standardem pro digitální podpis, který umožňoval message recovary. Nedostatky, které byly během roku 1999 odhaleny, vedly k návrhu různých opatření k odstranění možných bezpečnostních problémů. Zde je analyzováno pět z těchto návrhů.

Naccache,Coron,Joye,Pailier **- New Attacks on PKCS# v. 1.5 Encryption**
Prezentace dalšího významného výsledku z podzimu roku 1999. Publikovány zde byly technické detaily útoku. Připomeňme, že tento standard je nadále používán v současných komerčních produktech.

E.Jaulmes, A.Joux : **A NICE Cryptanalysis**
Prezentován chosen-ciphertext attack proti oběma verzím kryptosystému NICE . Systém NICE byl prezentován v roce 1999 jako nový možný kryptosystém s veřejným klíčem. Vzhledem k obecným podmínkám útoku to znamená, že tento systém nelze považovat za bezpečný.

P.Sarkar,S.Maitra : **Construction of Nonlinear Boolean Functions with Important Cryptographic Properties**
Nejednalo se o prezentaci výsledku světového významu, ale o velice dobře vypracovanou teorii, včetně návodu na praktické vyhledávání vhodných nelineárnách Booleovských vektorů, které jsou nutné při konstrukci vlastních kvalitních streamových šifer.

A.Biryukov,D.Wagner : **Advanced Slide Attacks**
D.Wagner (viz nepříliš vydařené foto z přednášky) představil nejnovější útok na blokové šifry Feistelova typu. Ukazuje se, že pokud je klíč používán opakovaně nebo spotřebováván periodicky, jedná se o vážnou chybu kryptosystému a útok pak lze použít bez ohledu na počet použitých rund - tj.zvyšováním počtu rund se nezvýší kvalita šifry. Útok byl předveden na různých variantách DESX a i na ruském šifrovém standardu GOST (verze 20 rund).

Přednášky zvaných řečníků :
Mike Walker - On the Security of 3GPP Networks
Vzhledem k známým útokům na verzi A5/1 (1999,2000) , která se používá mimo jiné i v ČR , se ukazuje nutnost zavést bezpečný provoz mobilních telefonů. Přednášející seznámil se specifikací WCDMA - "prvního standardu pro mobilní komunikaci - třetí generace ".

A.E.Sale - Colossus and the German Lorenz Cipher
Historické téma. Rekonstrukce zařízení Colossus, které za druhé světové války umožňovalo luštit německou šifru zařízení Lorenz.

Rump Session
Celkem předneseno 18 příspěvků.
Nejdůležitějším příspěvkem bylo pravděpodobně sdělení, které přednesl E.Biham, že po AES (novém americkém standardu pro šifrování, který nyní podrobí analýze NIST) se rozhodla evropská kryptologická obec vyhlásit vytvoření vlastního standardu - NESSIE (New European Schemes for Signature, Integrity and Encryption). K NESSIE viz samostaný článek v tomto sešitě.

Příští konference EUROCRYPT 2001 se bude konat ve švýcarském Innsbrucku.

E. CODE TALKERS

Díl III. - Od Iwo Jimy k mluvící figurce firmy Hasbro

Mgr. Pavel Vondruška, NBÚ

V roce 1942 žilo celkem 50 000 indiánů Navajů. Koncem roku 1945 z nich sloužilo 540 u námořnictva, z toho 375 (někde udáváno 420) jich sloužilo jako „code talkers“ – mluvčí v kódech. Indiáni, kteří prošli výcvikovým táborem v Pendeltonu v Kalifornii, byli nasazeni postupně do všech šesti amerických námořních divizí, které operovaly v Pacifiku. Zde sloužili od roku 1942 až do konce války. Jejich počet se postupně zvyšoval z 29 na cca 400. Předávali zprávy nejvyššího utajení. Výsledky nejkrvavějších bitev - Guadalcanal, Tarawa, Peleliu, Iwo Jima - často záležely na jejich přesné a rychlé práci. Major Howard Connor z páté námořní divize ve svých vzpomínkách píše, že kdyby nebylo „mluvčích v kódech“, nikdy by nebylo možné zvítězit u Iwo Jimy. V této divizi bylo zařazeno 6 Navajů. Během prvních dvou dnů této bitvy přijali přes 800 zpráv a všechny tyto zprávy byly přijaty bez chyby! Výkon, který pomocí klasických , tehdy používaných šifrových systémů nebylo možné dosáhnout. Operativnost, bezpečnost, rychlost a přesnost v předávání taktických zpráv přinesly Američanům v této bitvě vítězství.

Ještě dlouho po válce byly všechny informace o „tajné americké zbrani“ ve válce o ostrovy klasifikovány jako přísně tajné. Indiány Navajo nikdo neoslavoval a o jejich hrdinských činech a úmorné práci se nesmělo mluvit. Američané věděli, že se Japoncům nepodařilo kód prolomit, a tak Navajové „mluvčí v kódech“ byli ještě použiti ve válce v Koreji v roce 1950 a dokonce (což není příliš známá informace) v ještě v šedesátých letech ve válce ve Vietnamu. Ani v těchto válkách nebyl protivník úspěšný a kód prolomen nebyl. Současně to ukazuje, jak tajný byl celý projekt a jak dlouho se jej a příslušné kódy podařilo udržet v tajnosti.

Od roku 1969 byla postupně veřejnost seznamována s některými skutečnostmi, které se „mluvčích v kódech“ týkaly. V roce 1971 prezident Nixon oficiálně poděkoval všem Navajům, kteří se během světové války zasloužili svým „patriotismem, důmyslností a kuráží“ o vítězství USA nad Japonskem. V roce 1983 byl vyhlášen čtrnáctý duben : „Národním dnem mluvčích v kódech“ (National Code Talkers Day) na památku všech mužů, kteří sloužili za druhé světové války v Tichomoří. Prezident Ronald Reagan osobně udělil válečným veteránům – „mluvčím v kódech“ vysoká státní vyznamenání. V roce 1988 založil jeden z válečných veteránů indián Richard Mike ve své restauraci v navajské rezervaci Kayenta muzeum na památku činů těchto speciálně

vycvičených indiánů. Muzeum je velice dobře známé i v Japonsku. Návštěva je doporučována japonskými cestovními kancelářemi v průvodcích po USA. Japonci se zde na své cestě ke Grand Canyonu často zastavují.

Na veřejnosti se postupně objevovaly ukázky kódů, které byly za druhé světové války používány. Celý kódový materiál byl nakonec odtajněn 3.11.1999. V příloze je uvedena kódová kniha, která byla používána v posledních dnech druhé světové války. Podle této knihy jsem také vytvořil název druhého dílu tohoto volného vyprávění o „mluvčích v kódech“ - YIL-TAS GLOE-IH-DOT-SAHI UT-ZAH, což znamená „kód bude úspěšný“.

Kód byl opravdu úspěšný, přinesl Američanům pravděpodobně vítězství v bitvě o ostrovy. Jak to ale bylo se skutečnou kryptologickou silou kódového systému? Opravdu byli Japonci proti němu bezmocní? Na tyto otázky nám částečně pomůže odpovědět příběh seržanta Joe Kieyoomia z druhé světové války.

Seržant Joe Kieyoomia mohl za druhé světové války sehrát téměř rozhodující úlohu v bitvě o ostrovy. Byl totiž indián z kmene Navajo, nesloužil u amerického námořnictva, ale u dvousté dělostřelecké brigády. Po kapitulaci Filipín (1942), byl zajat a v japonském zajetí strávil 43 měsíců. Krátce po svém zajetí byl oddělen od jednotky a poslán do Japonska – do města Nagasaki. Japonci si o něm mysleli, vzhledem k jeho jménu a barvě pleti, že není Američan, ale Japonec, který sloužil v americké armádě a jako takový měl být řádně vyslechnut a po té odsouzen. Japonci mu zpočátku nevěřili, že v USA žijí i lidé jiné pleti než bílé a černé a že je rodilý Američan. O jeho případ se zajímala i japonská rozvědka. Po mnoha dnech strádání a utrpení (včetně hladovění a bití) se stalo něco nečekaného, Joa navštívila dvě krásná japonská děvčata a napsala mu na tabulku několik slov v navajštině. Joe musel říkat, co ta slova v angličtině znamenají. Pamatoval si, že mezi slovy byly výrazy pták, želva, voda. Joe nic nevěděl o „mluvčích v kódech“ a nevěděl, že by mohl pomoci Japoncům k dekódování těch nejtajnějších zpráv. Vzhledem k problematické možnosti zachytávání slov (viz popis jazyka) a vzhledem k tomu, že předkládané texty byly vytvořeny pomocí kódové knihy, nebyly Japoncům Joevy překlady příliš platné. Japonci pochopili, že se jedná o kód v navajštině a chtěli tento kód od Joea za každou cenu získat. Jednoho zimního dne Joa odvedli bosého ven. Joe musel stát bos ve sněhu při teplotě 27 stupňů pod nulou. Bylo mu řečeno, že zde bude stát tak dlouho, dokud neprozradí navajský kód. Teprve po hodině jej odvedli zpět do cely. Joe nemohl prozradit, do čeho nebyl zasvěcen. Joe vzpomínal, jak si přál zemřít, ale Japonci jej hlídali a rafinovaně mučili. Po několika dalších mučeních nakonec Japonci pokusy získat kód od Joea vzdali. Joe zůstal v zajetí ve věznici v Nagasaki. Zde

dokonce zažil i výbuch druhé atomové bomby, která explodovala nad Nagasaki. Tento výbuch, chráněn tlustými zdmi své cely, přežil. Byl osvobozen tři dny po výbuchu atomové bomby. Teprve rok po svém osvobození se dozvěděl od amerických úřadů o „mluvčích v kódech“ a musel se zavázat, že o svých zážitcích nebude po dobu utajení celého systému mluvit. Jeho příběh byl publikován teprve v roce 1997.

Tento příběh dokazuje, že Japonci byli v luštění kódu dále, než Američané v roce 1945 tušili a je pravděpodobné, že kdyby měli Japonci k dispozici velký počet dobře zachycených zpráv a příslušnou analýzu situace, ke které se zprávy vztahovaly, že by kód japonští kryptoanalytici prolomili…

Pokud v USA něco vzbudí zájem médií a veřejnosti, je snaha to i komerčně využít, a tak ještě v tomto roce má Hollywood natočit dokonce hned dva filmy, které budou barvitě líčit příběhy, které „zažili“ Navajové během druhé světové války. Známá firma na hračky Hasbro Inc. , v lednu tohoto roku vydala roztomilou figurku indiána GI Joe. Jedná se o indiánského spojaře z druhé světové války - „mluvčího v kódech“. Je to dokonce první figurka ze série figurek vojáků, které firma Hasbro vyrobila, která mluví. Ano, GI Joe mluví navajštinou a dokonce nahrávku připravil veterán z druhé světové války - Sam Billison. Sam Billison je prezidentem Navajo Code Talker Association. Přiznám se, že právě tato figurka (USD 24.99) mě inspirovala k sepsání těchto řádků, které se aspoň trochu snažily poodhalit pravdu o „mluvčích v kódech“ dříve, než příběhy hollywoodského stylu vytvoří úplně jiný, pro diváky „zajímavější“ obrázek - legendu. V jednom z filmů prý budou líčeni tito indiáni jako parašutisté, kteří byli shozeni do vnitrozemí ostrova a zde připravují podmínky k vylodění americké námořní pěchoty , tak jako skuteční „code talkers“ mají i oni vysílačku, ale také granáty, moc granátů a vrhací nože a umí se plížit jako praví indiáni …

Takže nashledanou v kině.

Obr.1 - „Code Talkers“
Obr.2 - medaile udělovaná prezidentem Renaldem Reganem válečným veteránům
Obr.3 - hymna námořních jednotek, kterou v roce 1944 přepsal indiánský instruktor Jimmy King do navajštiny
Obr.4 - figurka GI Joe od firmy Hasbro

F. Letem šifrovým světem

1. (J.Pinkava) Ve dnech 30.-31.května 2000 vyšlo nové číslo RSA Bulletinu: http://www.rsasecurity.com/rsalabs/bulletins/index.html obsahující článek: Robert D. Silverman (RSA Laboratories): A Cost-Based Security Analysis of Symmetric and Asymmetric Key Length.
   Z článku: "Zatímco článek Lenstry a Verheula [1] dospívá k závěru, že 1024 bitový klíč bude bezpečný pouze do roku 2002, shledáváme tento závěr za neopodstatněný. Toto tvrzení bylo učiněno za předpokladu, že 56-bitová DES byla zranitelná již v roce 1982, zatímco ve skutečnosti byla DES fakticky rozbita teprve v roce 1997. Může někdo věřit tomu, že problém, který je 7-milionkrát těžší než RSA-512 (a vyžaduje 6 Terabajtů paměti), bude řešitelný během několika málo roků, když RSA-512 bylo teprve nyní právě rozbito? Cena pamětí a obtížnost přípravy příslušného hardware pro řešení související matice dává možnost tvrdit, že 1024 bitové klíče budou bezpečné ještě nejméně 20 let (pokud nebudou vynalezeny nové neočekávané faktorizační algoritmy). Dnes neexistuje hardware, který by umožnil útok na 1024 bitový klíč metodou NFS. Diskuse o totálním počtu cyklů na Internetu je irelevantní, pokud neexistují počítače dostatečně velké, aby na nich mohla běžet NFS.“

2. Pokud sháníte informace o virech a antivirových programech, doporučuji velice dobře udržovanou stránku 18-ti letého studenta Igora Háka (Igiho) na URL adrese : www.viry.cz. Lze se zde zapsat i do konference o virech . Konference má v současné době asi 250 účastníků.

3. V dubnu byl v kanadském Quebecu zatčen patnáctiletý hacker, známý pod přezdívkou Mafiboy. Mladý hacker byl obviněn za vniknutí do serveru CNN.com. Na základě dalšího šetření byl také obviněn za účast na sérii útoků na Yahoo!, Amazon.com, Buy.com a Excite. Při proniknutí na server známé americké televizní stanice CNN bylo vyřazeno krátkodobě z činnosti na 1200 internetových stránek a škoda dosáhla několika miliónů dolarů. Vzhledem k tomu, že hacker ještě není plnoletý, hrozí mu odnětí svobody do dvou let. (ČTK).

A. Ohlédnutí za I.ročníkem sešitu Crypto-World 1999/2000

Mgr. Pavel Vondruška (NBÚ)

Rok 1999 byl pro skupinu odborníků sdružených v kryptologické sekci Jednoty českých matematiků a fyziků - GCUCMP (Group of Cryptology Union of Czech Mathematicians and Physicists) velmi úspěšný. Vyvrcholením jejich téměř dvouletého úsilí bylo uspořádání mezinárodní konference Eurocrypt ´99 v Praze. Tato konference patří v "kryptologickém kalendáři" mezi dvě celosvětově nejdůležitější akce (druhou je konference Crypto, která se pravidelně koná v USA v Santa Barbaře). Eurocrypt je "putovní" konference a postupně se pořádá v různých městech Evropy. Uspořádání takovéto konference je pro příslušný stát a jeho odborné kryptologické struktury vždy velkým oceněním jejich práce. Podle kladných ohlasů se zdá, že konference v Praze se vydařila a zařadila se mezi ty lepší Eurocrypty. Pravidelné schůze organizačního výboru skončily vyhodnocením konference v létě 1999.

Po skončení konference mi bylo až trochu líto opustit kryptodění a zdálo se mi, že mám najednou spoustu volného času (v rámci organizačního výboru jsem měl mimo jiné na starosti e-mail schránku konference). Také jsem si zvykl na téměř dvouletý styk s výborem IACR, přednášejícími, studenty, stipendisty (mezi něž patří např. dnes již hvězda první velikosti Biruyukov, pro kterého jsme tehdy vyřizovali slevy).

Z těchto - částečně nostalgických - důvodů jsem se nabídl, že se pokusím zorganizovat psaní jakéhosi sešitu, který by byl určen pro členy GCUCMP a sloužil k informacím o dění ve světě kryptologie. Přiznám se, že jsem počítal s tím, že se zapojí svými příspěvky i někteří další členové GCUCMP. Nejjednodušší formou se zdálo být napsání sešitu v MS Wordu a jeho rozesílání e-mailem na adresu členů GCUCMP. Hned od druhého čísla se však ozvalo pár zájemců mimo GCUCMP. Rozhodl jsem se, že budu sešit rozesílat všem zájemcům a vznikla tak databáze registrovaných odběratelů. Se sešitem mi od začátku velice pomohl ing. Jaroslav Pinkava, CSc., kterému touto cestou velice děkuji. Nejen za to, že pravidelně do sešitu přispívá, ale také za mnohá upozornění na zajímavé články a odkazy, které pak mohu využít v rubrice "Letem šifrovým světem".

Během roku pak došlo k některým změnám. Sešit začal "vycházet" v PDF formátu, koncem roku 1999 jsem vytvořil jednoduchou www stránku (http://www.mujweb.cz/veda/gcucmp), na kterou jsem umístil starší čísla. Poněkud mě totiž časově zatěžovalo zasílat "stará" čísla sešitů jednotlivým zájemcům. Zpravidla nově registrovaný uživatel měl zájem i o všechna starší čísla.

Množství čtenářů se pomalu, ale pravidelně zvyšuje; zájem znatelně vzrostl po konferencích ČAČK a Security 2000, kde bylo ze sešitu veřejně citováno. Po uveřejnění možnosti registrovat se pro zasílání tohoto časopisu v diskusi o virech (červen 2000) pak počet zájemců vzrostl o dalších více než padesát odběratelů.

Statistika nárůstu odběratelů , počtu stran a délky sešitu v bytech je následující:

I.ročník sešitu Crypto-World

	9/99	10/99	11/99	12/99	1/2000	2/2000
Odběratelů	25	31	35	47	62	76
Stran	7	10	9	9	9	11
Bytů	118 655	163 382	312 601	370 720	208 173	215 768

	3/2000	4/2000	5/2000	6/2000	7-8/2000	7-8/2001
Odběratelů	90	102	107	116	163	890
Stran	11	13	15	16	19	40
Bytů	212 279	333 340	354 749	502 347	280 000 ?	2 150 000

V posledním sloupci je uveden odhad, který vznikl proložením křivky údaji 9/99 až 7-8/2000 (viz komentář níže).

Odhad sledovaných ukazatelů - počet listů a velikost rozesílaného sešitu - mohu ovlivnit. Budu se snažit stabilizovat tyto parametry na rozumných hodnotách 12-16 stran, 400-600 kB. Odběratelé se tedy nemusí obávat dalšího nárůstu velikosti rozesílaného souboru a doby, kdy by přijatý Crypto-World obsadil všechen (zlým správcem povolený) prostor v jeho poštovní schránce.

K počtu odběratelů bych poznamenal, že uvedený odhad je sice velice příznivý a povzbuzující, ale současně si dovolím tvrdit, že takový nárůst zcela určitě nenastane. V současné době již většina expertů, kteří v dané oblasti pracují, sešit odebírá, a tak jaksi potenciálních čtenářů již asi ani tolik není (pokud ovšem doba PKI, e-komerce a e-obchodu a e-peněz nevytvoří nové e-čtenáře …). K současnému složení čtenářů prozradím, že přibližně 80 odběratelů jsou odborníci z oblasti informační bezpečnosti, přibližně 50 odběratelů jsou správci sítí nebo informačních systémů, 6 čtenářů jsou novináři odborných časopisů nebo obecněji novináři a cca dvacet pět zájemců neumím vzhledem k absenci údajů zařadit .

Když se již zmiňuji o struktuře odběratelů, uvedu ještě malou statistiku, která vznikla na základě údajů z 28.6.2000:

- sešit je rozesílán na 163 e-mail adres
- sešit je rozesílán do dvou států (156 x ČR, 7 x Slovensko)
- registrováno je pět čtenářek
- nejvíce čtenářů má svoji adresu registrovánu na doméně post.cz (12x)
- následují domény : volny.cz (10x), nbu.cz (8x), cuni.cz (8x), aec.cz (7x), decros.cz (6x), cvut.cz (5x), army.cz (3x), mvcr.cz (3x)
- zbývajících 113 čtenářů je registrováno na dalších různých 90 doménách
- 96 odběratelů je mi osobně známo

II.ročník

Prvé číslo II.ročníku (9/2000) vyjde kolem 10.září. Pokud mi to čas dovolí, pokusím se v tomto novém ročníku provést určité změny. Sešit bude mít nové logo a titulní stránku. Dále chystám nepříliš náročnou soutěž pro čtenáře, která by měla končit číslem 12/2000. Pokud se podaří najít sponzora, mohl by vítěz získat mimo slávy i nějaký "vánoční dárek". Asi jste již zjistili, že se změnila i www stránka (http://www.mujweb.cz/veda/gcucmp) , nejdůležitější změnou je možnost registrace k odběru sešitu přímo vyplněním registračního "formuláře" na www stránce a možnost zaslat dotaz nebo komentář také přímo z komunikačního okna na www stránce. Přislíbeny jsou i některé velmi hodnotné články od nových autorů.

FAQ (Frequently Ask Question)

Závěrem si dovolím odpovědět na často kladené otázky :

- ano, sešit píši a rozesílám zadarmo
- za články uveřejněné v sešitě se neplatí
- jsou vítány příspěvky všech odběratelů
- vedení sešitu patří mezi mé záliby a pokusím se jej vydávat dle svých možností i nadále

END

Všem čtenářům tohoto sešitu přeji hezké prožití zbytku letních prázdnin a dovolených.

B. Kryptosystém s veřejným klíčem XTR

Ing. Jaroslav Pinkava (AEC spol. s r.o.)

1. Úvod

Na adrese http://www.ecstr.com/ byl nedávno konečně zveřejněn design nového kryptosystému s veřejným klíčem, který autoři Arjen R. Lenstra a Eric R. Verheul nazvali XTR. Zveřejněný materiál je preprintem článku, který byl přijat k opublikování na konferenci Crypto 2000 v Santa Barbaře (koná se 20. – 24. srpna tohoto roku). Čtenáři Crypto-Worldu již byli o existenci tohoto kryptosystému stručně informováni v čísle 4/2000.

Systém XTR je založen na nové metodě umožňující reprezentovat prvky podgrupy multiplikativní grupy konečného tělesa. Cílem návrhu XTR je dle autorů navrhnout takový kryptosystém s veřejným klíčem, jehož délka parametrů i vlastní výpočtové nároky vedou k podstatným úsporám jak v komunikacích tak při výpočtech a to bez snížení příslušné kryptografické bezpečnosti.

2. Některá značení a definice

Popíši příslušný postup jen s nezbytnými technickými podrobnostmi. Zdůvodnění a další detaily lze nalézt v komentovaném článku [1].

GF(m) ... těleso (mod m)

GF(m)* ... multiplikativní grupa tělesa GF(m)

Budeme dále předpokládat, že p je takové prvočíslo, že

a) $p \equiv 2 \mod 3$

b) mnohočlen (tzv. šestý cyklotomický – viz [2]) $\varphi_6(p) = p^2 - p + 1$ spočtený v p má jako dělitele prvočíslo q.

Symbolem g bude označen generátor $GF(p^6)^*$ mající řád q.

Pro výše zvolené p lze libovolný prvek $GF(p^2)$ vyjádřit jako $x_1 a + x_2 a^2$, kde x_1, x_2 jsou z GF(p), a a a^p jsou kořeny polynomu $X^2 + X + 1$, které tvoří optimální normální bázi pro $GF(p^2)$ nad GF(p).

Jestliže h ε GF (p^6), pak k němu sdruženými prvky nad GF (p^2) jsou h, h^{p2}, h^{p4}.
Stopou Tr(h) nad GF (p^2) prvku h ε GF (p^6) je součet sdružených nad GF (p^2) prvku h, tj. $Tr(h) = h + h^{p2} + h^{p4}$. Platí Tr(h) ε GF ($p^2$).
Pozn.: p2= p^2, p4 = p^4.

Označíme F(c, X) mnohočlen $X^3 - cX^2 + c^pX - l$, pro c ε GF (p^2) mající kořeny h_0, h_1, h_2 v GF (p^6). Pro n ε Z budeme značit $c_n = h_0^n + h_1^n + h_2^n$. Z lemmatu 2.3.2 článku vyplývá, že c_n jsou prvky GF (p^2) .

Nechť dále $S_n(c) = (c_{n-1}, c_n, c_{n+1})$.

3. Základní algoritmy

Celý článek směřuje k vyhodnocení výpočetní složitosti matematických postupů nezbytných při provádění popisovaných kryptografických postupů. Jedním z ústředních algoritmů v tomto směru je algoritmus 2.3.7, který popisuje postup výpočtu $S_n(c)$.
Následující rovnost dává vlastně výchozí myšlenku konstrukce kryptosystému XTR:

$$S_n (Tr(g)) = (Tr(g^{n-1}), Tr(g^n), Tr(g^{n+1}))$$

Ukazuje totiž, že při nahrazení tradičních mocnin g jejich stopami lze dosáhnout výpočetně efektivních postupů. Konkrétně algoritmus 2.3.7 umožňuje na základě znalosti Tr(g) rychle spočítat $Tr(g^n)$.
Pro některé kryptografické postupy je však ještě třeba umět spočítat stopu součinu dvou mocnin generátoru g. Tím se zabývá algoritmus 2.4.8.

4. Volba parametrů

Symboly P a Q označíme požadované velikosti (v počtech bitů) hledaných prvočísel p a q. Autoři doporučují, že k dosažení bezpečnosti odpovídající bezpečnosti např. RSA v délce 1024 (počet bitů součinu dvou prvočísel) je vhodné volit P ≈ 170 a Q ≈ 160.
Algoritmus 3.1.1. Nalézt přirozené r tak, že $q = r^2 - r + 1$ je prvočíslo délky Q a dále nalézt přirozené k tak, že p = r + k*q je prvočíslo délky P a p ≡ 2 mod 3.
Tento algoritmus nám sice dává potřebná prvočísla (navíc prvočíslo p takto generované má určité výpočetně výhodné vlastnosti), ale nemusí být úplně ideální z bezpečnostního hlediska. Autoři proto uvádí ještě Algoritmus 3.1.2 jako metodu generování p a q , která je oproštěna od možného zjednodušení při kryptoanalytickém použití metody Number Field Sieve pro řešení diskrétního logaritmu. Algoritmus 3.2.2 se zabývá postupem nalezení Tr(g) – není nutné přitom znát samotné g.
Součástí dat pro veřejný klíč kryptosystému XTR je výše uvedená dvojice prvočísel p a q a stopa Tr(g) generátoru g. Tato čísla mohou být sdílena více uživateli (jako je tomu např. u DSA či ECDSA). Veřejný klíč konkrétního uživatele je pak doplněn hodnotu $Tr(g^k)$ pro nějaké přirozené číslo k, které je utajováno (je to tedy příslušný soukromý klíč).

5. Použití v kryptografii

Autoři uvádějí tři postupy – analogii DH dohody na klíči, ElGamalova šifrování a analogii Nyberg-Rueppelovy varianty digitálního podpisu s obnovou zprávy. Následuje popis analogu Diffie-Hellmanova protokolu pro dohodu na klíči :

1. Alice zvolí náhodně přirozené a < q-2, spočte $Tr(g^a)$ a zašle ho Bobovi.
2. B obdobně zvolí přirozené b < q-2, spočte $Tr(g^b)$ a zašle ho Alici.
3. Alice spočte $Tr(g^{ab})$ a dohodnutým postupem odvodí klíč K.
4. Stejně tak Bob spočte $Tr(g^{ab})$ a dohodnutým postupem odvodí klíč K

Výpočty se opírají o použití algoritmu 2.3.7.

V další části článku se autoři zabývají srovnáním vlastností kryptosystému XTR s kryptosystémy RSA a ECC. Dokladují výhodnost jimi navrhovaného postupu. Potřebná délka klíčů je srovnatelná s ECC a totéž platí i o výpočetní náročnosti kryptografických operací.

Ve zbývající části práce jsou popsány některé přístupy k hodnocení bezpečnosti navrhovaného kryptosystému.

6. Shrnutí

Kryptosystém XTR představuje myšlenkově velice hodnotný postup, inovátorský z hlediska metod současné asymetrické kryptografie. Čtenáře mající zájem o konkrétní implementace kryptosystému XTR musím však trochu varovat. Pro praktické aplikace je nejlépe využít takové kryptosystémy, které jsou již součástí mezinárodních norem. Svým způsobem to také garantuje, že daný kryptosystém již prošel dostatečně fází kritického posuzování svých vlastností odbornou veřejností (jako je tomu např. u systému RSA a u systémů založených na úlohách diskrétního a eliptického diskrétního logaritmu). Z tohoto hlediska je systém XTR teprve v plenkách. Je také možné, že než kryptosystém nabyde své definitivní podoby (i třeba např. z hlediska optimalizace implementačních vlastností) dojde k jeho některým dílčím úpravám. Navíc autoři oznámili, že bylo podáno několik mezinárodních patentů, které se tohoto kryptoschematu dotýkají.

C. Fermatův test primality, Carmichaelova čísla, bezčtvercová čísla

Mgr. Pavel Vondruška (NBÚ)

Část II.

V minulém sešitě - 6/2000 - jsme si uvedli některé pravděpodobnostní testy pro získání prvočísel. Blíže jsme se seznámili s Fermatovým testem primality a při jeho teoretickém rozboru jsme se setkali s pojmem Carmichaelovo číslo. Těmito čísly jsme se dále zabývali. V závěru jsme uvedli charakteristické vlastnosti těchto čísel.
Jedna z vlastností byla : "Každé Carmichaelovo číslo je bezčtvercové."
V této části se budeme právě bezčtvercovými čísly zabývat.

Bezčtvercová čísla

Číslo n se nazývá bezčtvercové (anglicky Squarefree), jestliže jeho prvočíselný rozklad obsahuje každého činitele pouze v prvé mocnině.

Všechna prvočísla jsou tedy triviálně čísla bezčtvercová.
Příkladem bezčtvercových čísel jsou : 1, 2, 3, 5, 6, 7, 10, 11, 13, 14, 15, ...
Naopak čísla 4, 8, 9, 12, 16, 18, 20, 24, 25, ... nejsou čísla bezčtvercová (anglicky se označují squareful numbers).

Výpočtem byly zjištěny následující výsledky :

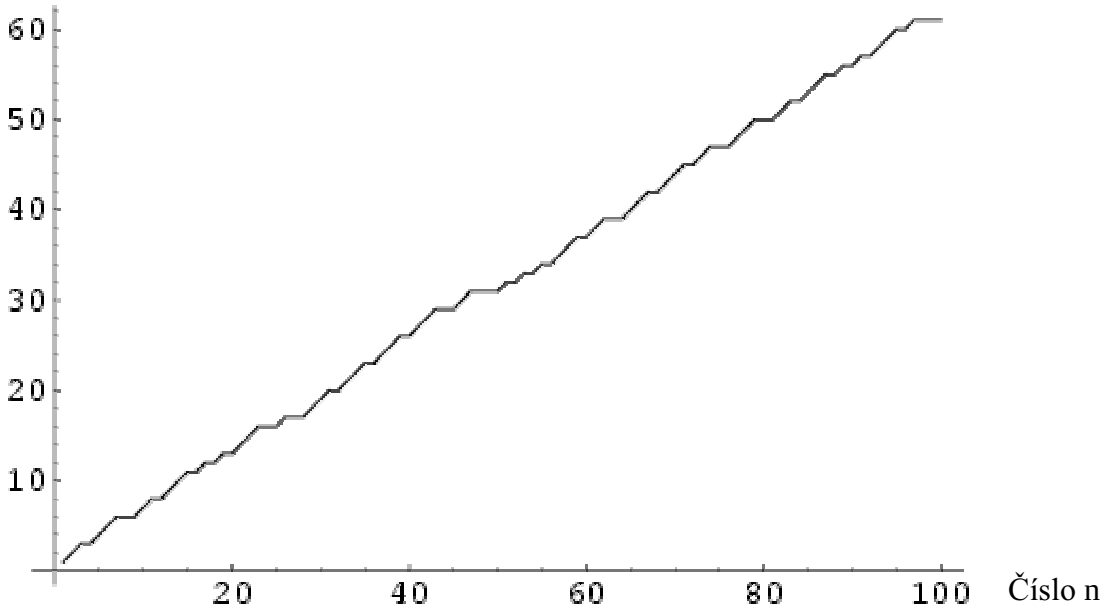
Interval <1 , n >	Počet bezčtvercových čísel	Počet prvočísel
10	7	4
100	61	25
1000	608	168
10 000	6 083	1 229
100 000	60 794	9 592
1 000 000	607 926	78 498

Významné práce o problému bezčtvercových čísel publikovali : (6) Nagell 1951, p. 130; (4) Landau 1974, pp. 604-609; (3) Hardy and Wright 1979, pp. 269-270; (2) Hardy 1999, p. 65.

Na grafu závislosti počtu bezčtvercových čísel na číslu n (obr. 1) lze vypozorovat jistou pravidelnost rozložení bezčtvercových čísel.

Obecně lze říci, že rozložení bezčtvercových čísel je na rozdíl od prvočísel "docela pravidelné". Právě pro tuto vlastnost a současně proto, že jsou s prvočísly v těsném vztahu, jsou bezčtvercová čísla v teorii čísel využita pro některé odhady a důkazy, které se týkají prvočísel. Přesnější vyjádření (a zdůvodnění) přesahuje rámec našeho jednoduchého výkladu.

Počet bezčtvercových čísel



Obr. 1 - Závislost počtu bezčtvercových čísel na volbě n

Z "přesnějších" odhadů uveďme odhad počtu bezčtvercových čísel $Q(x) \leq n$

$$Q(n) = \frac{6n}{\pi^2} + \mathcal{O}(\sqrt{n}) \quad .$$

Asymptotická hustota tohoto výrazu je $1/\ \zeta(2) = 6/\ \pi^2 \approx 0.607927$ (kde $\zeta(2)$ je hodnota Riemannovy ζ funkce v bodě 2) .

Hardy a Wright 1979 (3, str. 270) studovali tzv. Möbiovu funkci $\mu(n)$, která je definována následovně :

$$\mu(n) = \begin{cases} 0 & \text{pro n, které má ve svém prvočíselném rozkladu alespoň dvě prvočísla stejná} \\ 1 & \text{pro n=1} \\ (-1)^k & \text{pro n, které má ve svém prvočíselném rozkladu všechny činitele různé a těchto činitelů je k} \end{cases}$$

Je zřejmé, že je-li $\mu(n)$ různé od nuly, je n bezčtvercové číslo.

Asymptotická hodnota funkce Q(x) je rovna hodnotě :

$$\sum_{n=1}^{x} \left| \mu(n) \right| = \frac{6x}{\pi^2} + o(x)$$

Není znám algoritmus, který by v polynomiálním čase řešil otázku, zda přirozené číslo je nebo není bezčtvercové číslo. Je zřejmé, že tento problém úzce souvisí s problémem faktorizace, neboť umíme-li číslo rozložit na jednotlivé činitele, pak snadno určíme, zda je

nebo není bezčtvercové. Na druhou stranu není známo, zda neexistuje algoritmus, který by nám určil, že číslo je bezčtvercové, aniž bychom museli znát jeho rozklad.

Zodpovězení této otázky se považuje za velice důležitý problém teorie čísel, výsledek by našel uplatnění v teorii NFS (number field sieve), velice nepřesně řečeno "okruh přirozených čísel vytvořený při výpočtu algebraického číselného pole by byl reducibilní pomocí bezčtvercových čísel" (Lenstra 1992, Pohst and Zassenhaus 1997). Řešení tohoto problému tak může výrazně ovlivnit bezpečnost RSA .

****

Přílohou k dnešnímu číslu je soubor 10000.txt, který obsahuje prvních 10 000 prvočísel. Tento soubor je uložen na adrese http://www.utm.edu/research/primes/lists/small/1000.txt.
Zde lze také získat soubor obsahující přehled prvních 100 008 prvočísel. V tomto souboru jsou uvedena všechna prvočísla z intervalu 1 až to 1 299 827. Velikost tohoto souboru je 822 kB. Pokud někomu nestačí ještě ani tento rozsáhlý soubor, doporučuji k návštěvě adresu : http://www.math.princeton.edu/~arbooker/nthprime.html
Zde můžete získat informace o prvních 1 000 000 000 000 prvočíslech. Posledním prvočíslem v tomto souboru je 29 996 224 275 833. Informace o prvočíslech získáte pomocí dotazů. Váš dotaz např. zní : "Jaké je sté prvočíslo?" , a program uložený na uvedené adrese vrátí příslušné prvočíslo = 541. Odpověď na libovolný dotaz od 2 do 10^{12} trvá cca 10 vteřin.

D. Počátky kryptografie veřejných klíčů

Mgr. Jan Janečko (Komerční banka, a.s.)

Rokem 1976 začala bezesporu nová éra kryptografie. Whitfield Diffie, Martin Hellman a Ralph Merkle objevili a zveřejnili zcela nový převratný kryptografický princip – princip veřejných šifrovacích klíčů. Tento průkopnický objev postupně vzbudil obrovský zájem specialistů a v následujícím období zcela změnil obraz kryptologie. Po prvních článcích a vystoupeních autorů této myšlenky se brzy objevily návrhy konkrétních systémů. Mezi prvními byly i oba z nejúspěšnějších a stále používaných představitelů asymetrické kryptografie, čili kryptografie veřejných klíčů (Public Key Cryptography, PKC) – v roce 1976 tzv. Diffie-Hellmanův systém výměny klíčů [1] a v roce 1977 algoritmus RSA [2], jehož autory jsou Ronald Rivest, Adi Shamir a Leonard Adleman (v té době všichni z MIT). Jmenovaní autoři si za své objevy získali zasloužený respekt a navždy se zapsali do historie svého oboru.

Postupem doby se však začaly objevovat určité pověsti, že tito vědci nebyli prvními objeviteli PKC. V kryptologii totiž existuje situace odlišná od většiny ostatních vědeckých oborů. Vedle otevřeného výzkumu existuje ještě výzkum utajovaný, prováděný elitními speciálními službami velmocí i dalších zemí, zahalený téměř neproniknutelným tajemstvím (viz též citát v závěru tohoto článku). Až do 70. let tato sféra v kryptologii naprosto dominovala, ale i v nynější době stále představuje velmi významný vědecko-výzkumný potenciál.

Říká se například, že už před rokem 1976 znala PKC americká NSA. V článku o kryptologii uveřejněném v Encyclopaedia Britannica [3] se uvádí, že bývalý ředitel NSA Bobby Inman bez důkazů tvrdil, že NSA znala princip PKC už o deset let dříve před jeho objevením otevřenou akademickou obcí. Určité potvrzení vidí někteří ve vývojovém projektu zabezpečeného telefonu STU-III, který využívá certifikátů, a jehož výzkum začal pravděpodobně v polovině 70. let. Přitom certifikáty se ve veřejné kryptografii objevily až v roce 1979. Jako možný podnět pro výzkum vedoucí k objevu PKC se také uvádí Memorandum prezidenta J. F. Kennedyho č. 160 z roku 1962 (a zvláště jeho Weisnerův dodatek) [4], týkající se potřeby zabezpečení nukleárních zbraní proti zneužití.

Nepopiratelný důkaz o tom, že princip PKC byl objeven už před rokem 1976, však nakonec přišel z Velké Británie. V roce 1997 byl uveřejněn článek Jamese Ellise z britské CESG (Communications – Electronics Security Group), nazvaný "The history of Non-Secret Encryption" [5], ve kterém jeho autor popisuje, jak princip asymetrické kryptografie (jím nazývaný jako Non-Secret Encryption, NSE) objevil už v roce 1970. Dále uvádí, že speciální variantu RSA objevil jeho kolega Clifford Cocks v roce 1973, varianty Diffie-Hellmanova systému výměny klíčů pak Malcolm Williamson brzy poté. Článek [5] napsal James Ellis v roce 1987, byl však zveřejněn až krátce po jeho smrti v prosinci 1997. Je v něm popsána celá historie objevu NSE pracovníky CESG. Spolu s příslušnými autentickými technickými zprávami CESG ([6] -[9]) ho lze najít na webovské stránce CESG www.cesg.uk.

Jak vlastně k objevu NSE došlo? J. Ellis uvádí, že už v 60. letech představovala velký problém distribuce šifrovacích klíčů tehdy používaných symetrických šifer pro potřeby ozbrojených sil. Až dosud bylo pokládáno za samozřejmé, že odesilatel i příjemce zašifrovaných informací musí předem sdílet nějakou utajovanou informaci. Inspirace, že tomu tak být nemusí, přišla z technické zprávy neznámého pracovníka Bellových laboratoří, publikované v roce 1944, která obsahovala návrh zabezpečeného telefonu. Utajení mělo být dosaženo tím, že příjemce vysílal do linky šum k maskování hovorového signálu, který by pak od přijatého maskovaného signálu opět odečítal. Přestože návrh nebyl technicky realizovatelný, vnukl Ellisovi myšlenku, že při aktivní účasti příjemce v procesu šifrování odesilatel a příjemce předem sdílet nějakou utajovanou informaci nemusí a celý systém může být veřejně známý. Od tohoto postřehu již pro něho nebylo obtížné dokázat existenční větu o tom, že "Non-Secret Encryption" je v principu možné. Důkaz vycházel z představy, že proces zašifrování lze vždy zcela obecně popsat pomocí matice, jejíž řádky a sloupce představují všechny možné klíče a možné zprávy, obsahem matice je pak příslušný šifrový text. I když by taková matice nebyla v praxi pro svoji ohromnou velikost realizovatelná, v principu si ji můžeme vždy představit.

Popišme nyní stručně hlavní myšlenku důkazu. Odesilatel chce utajeně poslat zprávu *p*. Příjemce generuje náhodný tajný klíč *k*, který zašifruje pomocí náhodně generované jednorozměrné tabulky (permutace) *M1* na hodnotu $x = M1(k)$ a tu zašle odesilateli zprávy. Ten použije *x* a tabulku *M2* (dvojrozměrnou, náhodně generovanou matici, jež indukuje pro každou pevnou hodnotu *x* prosté zobrazení) k zašifrování *p* na šifrový text *z*: $z = M2(p,x)$. Příjemce získá zpět původní zprávu *p* pomocí příslušné "inverzní" tabulky *M3*: $p = M3(z,k)$. Přitom matice *M1*, *M2* a *M3* nemusí být utajovány.

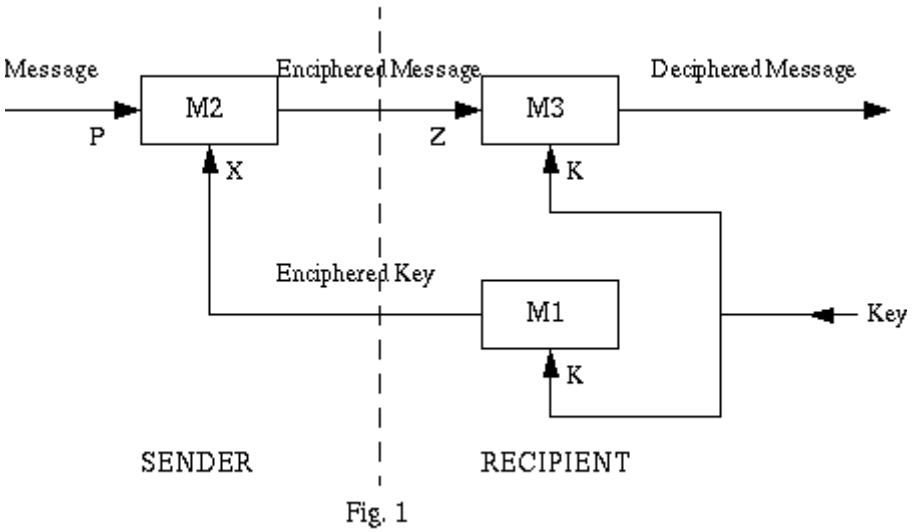

Fig. 1

Podrobněji je celý postup znázorněn na dalším obrázku (v dnešní terminologii se *k* nazývá soukromým a *x* veřejným klíčem):

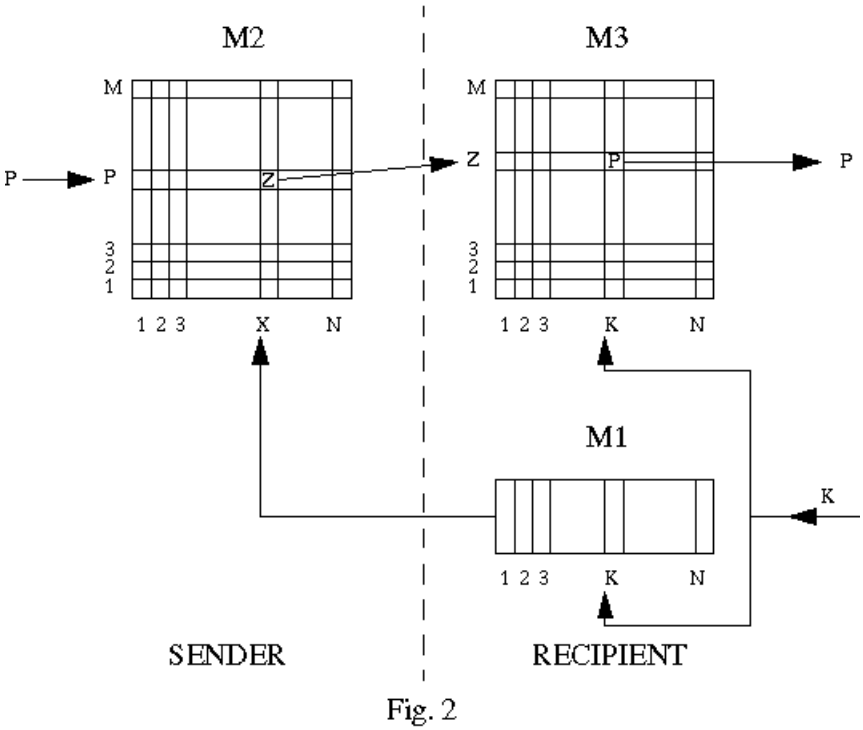

Fig. 2

Oba obrázky jsou převzaty z původní Ellisovy zprávy [6].

Je vidět, že metoda bude fungovat korektně, pokud *M3* bude zřejmým způsobem zkonstruována na základě matic *M1* a *M2*. Dále je vidět, že ani zveřejněním všech matic *M1, M2 a M3* není ohrožena důvěrnost zašifrované zprávy jejím přenosem k oprávněnému příjemci. Vzhledem k náhodnému vygenerování obsahu matic *M1* a *M2* totiž bez znalosti hodnoty *k* neexistuje jiná metoda luštění, než je metoda hrubé síly (prohledáváním tabulek *Mi*). Její úspěšnost je však vyloučena dostatečnou dimenzí matic (např. řádově 2^{100}).

Takto se tedy Jamesi Ellisovi podařilo dokázat, že asymetrické šifry mohou teoreticky existovat. Ellis však nedokázal najít jejich v praxi využitelnou realizaci. Správně však předpokládal, že prakticky použitelný systém může mít jinou formu, než kterou použil pro svůj důkaz. Svou prací ale ukazoval směr, jakým je možno se zaměřit. Svůj výsledek prezentoval poprvé v lednu 1970 v interní technické zprávě CESG [6].

Jak sám J. Ellis tvrdil, teorie čísel nebyla jeho silným oborem, s návrhy realizovatelných systémů proto přišli až jeho kolegové. V roce 1973 Clifford Cocks navrhl de facto speciální případ RSA [7]. Stručně řečeno, rozdíl mezi Cocksovým návrhem a RSA je v tom, že veřejným klíčem u Cockse je vždy přímo modul $n = pq$, u RSA to mohou být "vhodná" čísla e mající inverzi $mod\ \varphi(n)$ (v praxi se však obvykle stejně používá jediný veřejný klíč, např. Fermatovo prvočíslo $2^{16}+1$). Cocksův návrh vypadal takto:

1. Strana A generuje dvě velká prvočísla *p, q* taková, že *p* nedělí *q-1* a *q* nedělí *p-1*. Poté spočte $n = pq$. Číslo *n* jako veřejný klíč pošle straně B.
2. B zašifruje zprávu *m* tak, že spočte $c = m^n \bmod n$; šifrový text *c* pošle A.
3. A odšifruje *c* následovně: najde *p'* a *q'* taková, že $pp' = 1 \bmod q-1$ a $qq' = 1 \bmod p-1$. Pak platí, že $m = c^{p'} \bmod q$, $m = c^{q'} \bmod p$ a pomocí Čínské věty o zbytcích A zjistí otevřený text *m*.

To ale nebylo od CESG všechno. Po C. Cocksovi přišel s jinými návrhy Malcolm Williamson. Byly založeny na složitosti výpočtu diskrétního logaritmu. Prvním systémem byl následující kryptografický protokol, který probíhal ve čtyřech krocích. Byl formulován obecněji pro konečné okruhy [8], ale pro prvočíselná tělesa ho lze popsat následovně:

Účastníci A a B si dohodnou neutajované velké prvočíslo *p*. Výpočty pak provádějí *mod p*.

1. A chce zaslat zprávu *m*. Generuje náhodně číslo *k* nesoudělné s *p-1* a spočte $x = m^k$; *x* pošle B.
2. B generuje náhodně číslo *l* nesoudělné s *p-1* a spočte $y = x^l = (m^k)^l$; *y* pošle A.
3. A pomocí Euklidova algoritmu nalezne *k'* takové, že $kk' = 1 \bmod p-1$ a spočte $z = (m^{kl})^{k'} = m^l$; tuto hodnotu pošle B.
4. B obdobným způsobem nalezne *l'* takové, že $ll' = 1 \bmod p-1$ a spočte $z^{l'} = (m^l)^{l'} = m$.

V další zprávě [9] Williamson dokonce navrhl klasický Diffie-Hellmanův protokol pro výměnu klíčů, a to pro obecná číselná tělesa. Zprávu uveřejnil mnohem později, než systém vymyslel:

Před začátkem protokolu si účastníci A a B dohodnou těleso $F = GF(p^q)$ a primitivní prvek *x* tělesa *F*. Tyto údaje neutajují. Prvky tělesa *F* reprezentují jako polynomy.

1. A generuje náhodně číslo *a* a spočte $y = x^a$; *y* pošle B.
2. B generuje náhodně číslo *b* a spočte $z = x^b$; *z* pošle A.
3. Obě strany spočtou $w = (x^b)^a = (x^a)^b = x^{ab}$; tuto hodnotu používají jako šifrovací klíč.

Jen jako historickou kuriozitu uveďme, že pracovníci CESG objevili varianty základních systémů PKC (RSA a DH) v opačném pořadí, než jak k tomu poté došlo v otevřeném výzkumu. Místo závěru bych pak chtěl uvést ještě jeden charakteristický citát z článku Jamese Ellise [5]:

„Kryptografie je nejneobvyklejší vědou. Většina profesionálních vědců se snaží publikovat svou práci jako první, protože prostřednictvím šíření tato práce realizuje svoji hodnotu. Naproti tomu nejúplnější hodnota kryptografie je realizována minimalizací informací dostupných potenciálním protivníkům. Proto profesionální kryptografové obvykle pracují v uzavřených komunitách, které poskytují dostatečnou odbornou interakci k zajištění kvality, zatímco udržují utajení před nezasvěcenými. Odhalení těchto tajemství je obvykle umožněno pouze v zájmu historické přesnosti až poté, co se ukáže nepochybným, že žádný další užitek nemůže už být z pokračujícího utajení získán."

Poznámka:

CESG – Communications-Electronics Security Group – je formální součástí známé britské speciální služby GCHQ (Government Communications Headquarters, Ústředí vládních komunikací). Sídlí v Cheltenhamu v hrabství Gloucestershire, asi 130 km západně od Londýna. GCHQ se proslavila už za 2. světové války (v té době ovšem působila pod názvem Government Code and & Cypher School - GC&CS, ale byla všeobecně známa pod názvem Bletchley Park podle svého tehdejšího sídla) rozluštěním nejtajnějších německých vojenských šifrátorů Enigma a Lorenz Geheimschreiber, stejně jako konstrukcí prvních elektronických počítačů na světě nazývaných Colosssus, sloužících právě k luštění německých šifrátorů. Přímým předchůdcem CESG byla London Communications Security Agency (LCSA), vzniklá v Londýně počátkem 50. let. Dnešní název nese od roku 1969. Postupně se služba přestěhovala do Cheltenhamu. Od roku 1997 již CESG není přímo financována vládou a pracuje na ziskové bázi. Mezi její hlavní úkoly patří účast na definování vládní politiky pro informační bezpečnost, konzultační a poradenské služby pro vládní i veřejný sektor v oblasti zavádění této politiky, vlastní vývoj kryptografických produktů (jako jsou zabezpečené telefony) a spolupráce s komerčními výrobci při vývoji kryptografických produktů pro vládní účely, provádění výukových kurzů a výroba spotřebních šifrovacích materiálů (klíčů).

E. Přehled některých českých zdrojů - téma : kryptologie

Vybral Mgr. Pavel Vondruška, NBÚ

Je léto, počasí nám zatím nepřeje, a tak zbude možná čas i na studium. Nabízím možnost prolistovat některé české internetové zdroje. Osobně se domnívám, že články na níže uvedených adresách obsahují řadu kvalitních informací a každý, kdo má o tuto problematiku zájem, zde jistě najde mnoho užitečného.

Seznam je nepochybně neúplný - nikoho jsem ovšem úmyslně nevynechal, ale jiné české zdroje (mimo jednotlivých článků v časopisech Chip, ComputerWorld, IT-NET apod.) ve své "databance" nemám. Uvítám proto upozornění na další vhodné zdroje a rád je v příštích číslech zveřejním.

Ing. Jaroslav Pinkava, CSc., AEC s.r.o.

Na www adrese http://www.aec.cz/ najdete ve sloupcovém menu volbu kryptologie.
Na této adrese je uložen kvalitně zpracovaný, rozsáhlý "Úvod do kryptologie" a dále 7 částí bulletinu AEC, který je věnován šifrování a obsahuje cenné odkazy na původní materiály. Připravuje se část věnovaná elektronickému podpisu. Soubory jsou uloženy v html podobě.

Na závěr si dovolím upozornit na dvouměsíčník "**Data Security Management**", který je věnovaný problematice bezpečnosti dat a je orientován na manažery. URL adresa je http://www.dsm.tate.cz

F. Letem šifrovým světem

1. Prezident republiky Václav Havel podepsal 11.7.2000 zákon o elektronickém podpisu. Tento zákon nabývá účinnosti 1.10.2000. Téměř současně proběhl podobný akt i v USA; prezident Bill Clinton podepsal americký zákon o elektronickém podpisu (Electronic Signatures in Global and National Commerce Act) na stejném místě, kde byl před 224 lety podepsán nejdůležitější akt v dějinách USA - Declartion of Independence. Bill Clinton symbolicky zákon podepsal elektronicky pomocí svého soukromého klíče.
   Mohl tak učinit i náš prezident ? Ano, mohl. Jak jsem zjistil při prohlížení vydaných certifikátů I.CA (www.ica.cz), má zde registrován svůj veřejný klíč (určen pro RSA, délka modulu 1024 bitů). Platnost klíče je omezena na kritickou dobu, kdy se vědělo, že prezident bude český zákon o elektronickém podpisu signovat (10.7.2000-24.7.2000). Sériové číslo tohoto certifikátu je : 72028. Subject : Vaclav Havel / email=vaclav.havel@hrad.cz . Připomenu, že Václav Havel podepsal náš zákon o elektronickém podpisu na své cestě po Balkáně - v Dubrovníku. Možná, že kdyby se akt nekonal mimo ČR, že by prezident také použil symbolicky elektronický podpis, možná …

2. Sdružení pro informační společnost (SPIS) uspořádalo 13.7.2000 happennig u příležitosti podpisu zákona o elektronickém podpisu prezidentem ČR (SPIS eSignature Construction Happening 2000). Na akci byli pozváni všichni, kteří se na přípravě a prosazování zákona o elektronickém podpisu podíleli. Setkání proběhlo v přátelské atmosféře a zbývá jen doufat, že naplnění zákona bude realizováno co nejdříve.

3. V květnu byl schválen důležitý dokument - evropský standard o formátech elektronického podpisu - ETSI ES 201733 (Electronic Signature Formats). Je volně dostupný na webowské stránce ETSI http://webapp.etsi.org/pda/ nebo na stránce ETSI věnované elektronickému podpisu http://www.etsi.org/sec/el-sign.htm .
   V průběhu července byla uveřejněna žádost o komentování draftu dokumentu, který se týká požadavků na jednotné hodnocení poskytovatelů certifikačních služeb, které vydávají kvalifikované certifikáty :“Policy Requirements for Certification Service Providers Issuing Qualified Certificates” (ETSI 155 T1 Draft H, 15.7.2000) . O rychlosti, s jakou ETSI pracuje, svědčí i datum do kdy se přijímají komentáře - 15.9.2000. Do konce roku 2000 vyjde celá řada dalších důležitých dokumentů. Osobně se domnívám, že by k jejich obsahu mělo být přihlédnutu při vytváření obdobných dokumentů - vyhlášek - úřadem ÚOOÚ, kterému ze zákona o elektronickém podpisu náleží dozor nad akreditovanými certifikačními autoritami a nad certifikačními autoritami vydávajícími kvalifikované certifikáty.

4. Michelle Finley uveřejnil článek "Phone Phreaks to Rise Again?" (http://www.wired.com/news/business/0,1367,36309,00.html). V článku popisuje nové možnosti útoků "telefonních hackerů", které umožňuje zavedení IP telefonie. Phreackeři jsou částí počítačového undergroundu a v minulosti (v 60-tých a 70-tých letech) nechvalně prosluli svými útoky proti telefonním technologiím. Finley upozorňuje, že novodobá technologie může vést k "zmrtvýchvstání" této dnes již téměř zaniklé komunity.

5. Z adresy http://www.rsasecurity.com/rsalabs/faq/index.html lze stáhnout novou verzi (datovanou k 27.6.2000) známého dokumentu "RSA Laboratories' Frequently Asked Questions About Today's Cryptography, Version 4.1". Velikost PDF verze je 1 521 172 bytů, zazipováno pouze 888 372 bytů.

6. (J.Pinkava) Autoři kryptosystému NTRU se rozhodli pro jeho patentování. Přestože původně byl kryptosystém předložen k zařazení do soustavy norem, kterou připravuje skupina IEEE P1363, nakonec se autoři (Jeffrey Hoffstein,Jill Pipher a Joseph H. Silverman) rozhodli jít cestou patentů. Přitom kryptosystém NTRU je z řady hledisek pro uživatele velice zajímavý. Jeho velkou předností je především dosahovaná rychlost práce vlastního algoritmu. NTRU byl nejprve prezentován Jeffrey Hoffsteinem na rump session na konferenci CRYPTO 96, publikován byl v roce 1998 (http://www.ntru.com).
   Novinkou je úmysl autorů využít tento kryptosystém k ochraně autorských práv digitalizovaných hudebních nahrávek
   http://www.nytimes.com/library/tech/00/07/biztech/articles/03pate.html).
   Např. firmy Greylock Management and Sony Corporation se rozhodly investicí ve výši 11 milionů dolarů podpořit vývoj této nové technologie.

Na závěr něco z letní okurkové sezóny :

7. ŠIFROVAT,ŠIFROVAT,ŠIFROVAT!
   Vladimír Železný zveřejnil informaci, že má k dispozici dokumenty, které dokládají, že americká společnost CME připravovala násilné ovládnutí TV NOVA. Jedná se o e-mailové texty posílané elektronickou poštou mezi manažery CME Johnem Schwalliem a Petrem Sládečkem. Texty byly získány z pevného disku příjemce. Je až zarážející, že manažeři takovéhoto mediálního gigantu nepoužívali k zálohování a pravděpodobně ani ke komunikaci některý šifrovací software.
   Problém bude ovšem s prokazováním autentičnosti e-mailů - nebyly elektronicky podepsány nebo označeny časovým razítkem. Při této příležitosti mne napadla otázka, jak se vyrovnají naše soudy s případným sporem, kdy jedna strana předloží jako důkaz dokument, který bude elektronicky podepsán, ale stalo se tak ještě před datem nabytí platnosti našeho zákona o elektronickém podpisu (1.10.2000)? Pokud je mi známo, zákon tuto situaci neřeší.

8. V Británii se začalo pracovat na projektu Noemova archa 21.století s cílem archivovat, tj. dokumentovat a bezpečně uložit na jednom místě obrázky a zvuky všech ohrožených zvířat a rostlin na světě. (http://www.arkive.co.uk).

9. Dobrovolný "internetový" vězeň DotComGuy, odkázaný jen na sebe a svůj počítač, oslavil malé jubileum svého pobytu v pronajatém domě v Dallasu. 26-ti letý inženýr Mitch Maddox se dobrovolně zavázal na dobu jednoho roku založit svůj život jen na využívání e-komerce. Nastěhoval se do prázdného domu a změnil své občanské jméno na přezdívku DotComGuy. Nyní je již 8 měsíců zavřený v obklíčení internetových kamer, přičemž pro své každodenní potřeby může využívat jen internet a služby, které tato síť poskytuje.

PATTERN AVOIDANCE IN INVOLUTIONS

ELIZABETH WULCAN

ABSTRACT. This work concerns pattern avoidance in involutions. We give a complete solution for the number of involutions avoiding one or two classical 3-patterns, mainly by relating these to well known combinatorial structures such as Dyck paths and Young tableaux. The results for single 3-patterns were previously obtained by Simion and Schmidt. However, we give new proofs in most cases. We also give some results for the number of involutions avoiding generalised patterns.

CONTENTS

1. INTRODUCTION

Classically a k-pattern p is a permutation of $[k] = \{1, 2, \ldots, k\}$ and a permutation π of $[n]$ is said to have an occurrence of p if π has a subword whose letters are in the same relative order as the letters of p. If π has no occurrences of p, we say that π avoids p. For example $\pi = 52134$ avoids $p = 132$ whereas $\pi = 41253$ has two occurrences of p (the subwords 153 and 253).

In the last decades there have been plenty of articles written on the subject of patterns and in particular on pattern avoidance. One of the earliest results worth mentioning is found in Knuth [7], where it is established that for all 3-patterns p, the number of permutations of $[n]$ that avoid p equals the nth Catalan number. In Simion and Schmidt [10], multiavoidance, that is when two or more patterns are simultaneously avoided, was considered and a full solution for the case of double avoidance was given. Simion and Schmidt also treated pattern-avoiding involutions, the topic of this work. Indeed, the results of Section 3, which concern the six classical 3-patterns, are all proven in [10]. However, we give new proofs of some of the results.

As a further development of the concept of patterns, Babson and Steingrímsson [3] introduced generalised patterns that allow the requirement that two adjacent letters in a pattern must be adjacent in the permutation for the pattern to occur. Avoidance of generalised patterns has been studied by, for example, Claesson [1], Kitaev [5], [6] and Claesson and Mansour [2]. In Section 4 we give some results for involutions avoiding generalised patterns.

Finally, in Section 5 we investigate double avoidance and give a complete solution for the number of involutions avoiding any two classical 3-patterns.

2. Preliminaries

Before starting the investigation on pattern-avoiding involutions we introduce the main concepts that will be used in this work. To start with, an *alphabet* X is a nonempty set of *letters* and a *word* over X is a finite sequence of letters from X. We denote the *empty word*, that is the word with no letters, by ϵ. Let $x = x_1x_2\cdots x_n$ be a word over X. A *subword* of x is a word $v = x_{i_1}x_{i_2}\cdots x_{i_k}$, where $1 \leq i_1 \leq i_2 \leq \cdots \leq i_k \leq n$. A *segment* is a word $v = x_ix_{i+1}\cdots x_{i+k}$. We define the *length of* x, denoted by $|x|$, to be the number of elements in x.

2.1. **Permutations.** Let $[n] = \{1, 2, \ldots, n\}$. A *permutation* π of $[n]$ is a bijection from $[n]$ to $[n]$. However, we sometimes refer to permutations of a subset A of $[n]$. This should be interpreted as a bijection from A to A. There are several different notations for the permutations, suitable for different purposes. A permutation π is usually seen as the word

$$\pi = \pi(1)\pi(2)\cdots\pi(n).$$

Another way of writing the permutation is given by the two line (or French) notation

$$\pi = \begin{pmatrix} 1 & 2 & \ldots & n \\ a_1 & a_2 & \ldots & a_n \end{pmatrix}.$$

This means that $1 \mapsto a_1$, $2 \mapsto a_2$ et cetera, hence the permutation is unaffected by rearrangement of the columns, which makes it easy to find the inverse of π. Indeed

$$\pi^{-1} = \begin{pmatrix} a_1 & a_2 & \dots & a_n \\ 1 & 2 & \dots & n \end{pmatrix}.$$

Rearranging the top line in increasing order gives π^{-1} as a word in the bottom line.

We will also use a third notation, the cycle form, where the letters in $[n]$ are grouped together in cycles. A cycle $(a_1 a_2 \cdots a_k)$ means that $a_i \mapsto a_{i+1}$ for $i < k$ and that $a_k \mapsto a_1$. Fixed points, that is those i for which $i \mapsto i$, are conventionally omitted. As will be shown in the example below, the cycle notation is generally not unique.

We denote the set of permutations of $[n]$ by $\mathcal{S}_n$.

Example 1. Consider the permutation

$$\pi = \begin{cases} 1 \to 3 \\ 2 \to 4 \\ 3 \to 6 \\ 4 \to 2 \\ 5 \to 5 \\ 6 \to 1 \end{cases}$$

We write it as the word

$$\pi = 346251,$$

or in the two line notation;

$$\pi = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 3 & 4 & 6 & 2 & 5 & 1 \end{pmatrix},$$

from which we get the inverse of π as

$$\pi^{-1} = \begin{pmatrix} 3 & 4 & 6 & 2 & 5 & 1 \\ 1 & 2 & 3 & 4 & 5 & 6 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 6 & 4 & 1 & 2 & 5 & 3 \end{pmatrix}.$$

The permutation π could be written in cycle form as

$$\pi = (136)(24)$$

but we also have

$$\pi = (24)(136) = (361)(24) = (42)(613).$$

This shows that the cycle notation is not unique. Note that the fixed point 5 is not written out.

2.2. **Involutions.** An *involution* is a permutation that is its own inverse. Thus an involution consists of cycles of length 1 or 2. We let $\mathcal{I}_n$ denote the set of all involutions of $[n]$.

2.3. **Generalised patterns.** A *generalised k-pattern* p is a word of length k consisting of all the elements of $[k]$, in which two letters may or may not be separated by a dash. Consider $\pi = a_1a_2\cdots a_n$ in $\mathcal{S}_n$. We say that the subword $v = v_1v_2\cdots v_k$ is a *p-subword* of π if the v_i's are in the same relative order as the p_i's and two adjacent letters of v are adjacent in π whenever the corresponding letters of p are not separated by a dash. We also refer to v as an *occurrence of p*. If π has no occurrences of p, we say that π *avoids* p or that π is *p-avoiding*. We define $\mathcal{S}_n(p)$ and $\mathcal{I}_n(p)$ to be the set of p-avoiding permutations and involutions in $\mathcal{S}_n$, respectively, and more generally we let $\mathcal{S}_n(A) = \bigcap_{p\in A}\mathcal{S}_n(p)$, just as $\mathcal{I}_n(A) = \bigcap_{p\in A}\mathcal{I}_n(p)$. It is convenient to regard the pattern p as a function from $\mathcal{S}_n$ to $\mathbb{N}$ where $p\pi$ is defined as the number of p-subwords of π. Thus π is p-avoiding if and only if $p\pi = 0$.

Usually the term pattern refers to the type of patterns p_1-p_2-$\cdots$-p_k with dashes between each pair of adjacent letters, that is, no attention is paid to whether the letters of the permutation are adjacent or not. Those patters were the first to be defined and studied and we therefore call them classical patterns.

Example 2. Regarded as a permutation statistic (a function from $\mathcal{S}_n$ to $\mathbb{N}$), the pattern (1-2-3) counts the number of increasing subsequences of length 3. For example, the longest increasing sequence of the permutation 21543 is of length two and consequently 21543 avoids (1-2-3).

The pattern (21) counts *descents* in a permutation, that is the number of i's such that $a_i > a_{i+1}$, just as (12) counts the *ascents*, the number of i's such that $a_i < a_{i+1}$.

The pattern $p = (1\text{-}32)$ counts the subwords of the form a_i-a_ja_{j+1} such that $a_i < a_{j+1} < a_j$. The permutation 25431 has two occurrences of p, namely 254 and 243.

2.4. **Young tableaux.** A *Young tableau P of shape $(n_1, n_2, \ldots n_m)$* is an arrangement of n distinct integers as an array of m left-justified rows, with n_i elements in row i, where $n_1 \geq n_2 \geq n_m \geq 0$ and $n_1+n_2+\cdots+n_m = n$. The entries of the rows and the columns must be ordered increasingly from left to right and from top to bottom, respectively. We write $P_{i,j}$ for the element in row i and column j.

Example 3. We have that

$$P = \begin{array}{|c|c|c|c|}\hline 1 & 3 & 4 & 9 \\ \hline 2 & 5 \\ \cline{1-2} 6 & 7 \\ \cline{1-2} 8 \\ \cline{1-1}\end{array}$$

is a Young tableau of shape $(4, 2, 2, 1)$ and that $P_{3,2} = 7$.

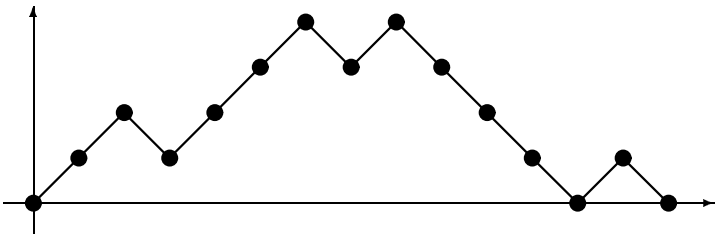

FIGURE 1. The Dyck path in Example 5

2.5. **Inversion tables.** Given a permutation $\pi = a_1 a_2 \cdots a_n$, we let $t(\pi) = (t_1, t_2, \ldots, t_n)$, where $t_i = |\{j : j > i, a_j < a_i\}|$. That is, the ith entry of t is the number of letters following the ith letter of π that are smaller than the ith letter.

A pair (a_i, a_j) is called an *inversion* of the permutation π if $i < j$ and $a_i > a_j$. Accordingly, t defined above is called the *inversion table* of π, since it gives a measure of the number of inversions that each letter of π causes.

It is easy to see that a permutation is uniquely determined by its inversion table, for a demonstration see for example Stanley [12].

Example 4. Consider $\pi = 1327654$. The corresponding inversion table is $t = (0, 1, 0, 3, 2, 1, 0)$, because there is no element smaller than 1 and there is exactly one element to the right of 3, namely 2, that is smaller than 3 et cetera.

2.6. **Dyck paths.** A *Dyck path of length 2n* is a lattice path from (0,0) to $(0, 2n)$ that consists of steps (1,1) and (1,-1) and that never goes below the x-axis. Denoting the steps (1,1) and (1,-1) by u (for up) and d (for down), a Dyck path can be written as a word over the alphabet $\{u, d\}$. The number of Dyck paths of length $2n$ is the nth *Catalan number* $C_n = \frac{1}{n+1}\binom{2n}{n}$. We denote the set of Dyck paths of length $2n$ by $\mathcal{D}_n$.

Example 5. The Dyck path of length $2 \cdot 7$ in Figure 3 is coded by the word *uuduuudddddud*.

3. PATTERN AVOIDING INVOLUTIONS

We start our work on pattern-avoiding involutions by investigating the avoidance of the six classical 3-patterns. For each such pattern we generate and study $\mathcal{I}_n(p)$, when n is small. When counting these involutions we obtain the first elements of the sequences that are presented in Table 1. Our aim is to show that the results are indeed true for all n.

For odd n, when $n/2$ is not an integer, it is natural to consider $\binom{n}{n/2}$ as $\binom{n}{\lfloor n/2 \rfloor}$ or $\binom{n}{\lceil n/2 \rceil}$, since the binomial $\binom{n}{k}$ coefficients are defined only for

p	$\lvert\mathcal{I}_n(p)\rvert$
(1–2–3)	$\binom{n}{n/2}$
(1–3–2)	$\binom{n}{n/2}$
(2–1–3)	$\binom{n}{n/2}$
(2–3–1)	2^{n-1}
(3–1–2)	2^{n-1}
(3–2–1)	$\binom{n}{n/2}$

TABLE 1. Classical patterns

integer n and k. However, $\binom{n}{\lfloor n/2\rfloor} = \binom{n}{n-\lfloor n/2\rfloor} = \binom{n}{\lceil n/2\rceil}$, so there should be no ambiguities concerning the interpretation. Let $\binom{n}{n/2} := \binom{n}{\lfloor n/2\rfloor}$.

It is observed that the involutions that avoid (2–3–1) are exactly the same as those that avoid (3–1–2), at least for small n. On the other hand we see that although $|\mathcal{I}_n(p)| = \binom{n}{n/2}$ for four different patterns p, there are no two distinct patterns p and q of these, such that $\mathcal{I}_n(p) = \mathcal{I}_n(q)$. The reader may convince himself of this by studying $\mathcal{I}_n(p)$ for small n.

3.1. **Avoiding p, when p is not an involution.** We consider the case when the pattern p itself is not an involution. As noticed above an involution avoids (2–3–1) if and only if it avoids (3–1–2). In this section this will be shown to follow from the fact that the patterns are inverses of each other. First, however, we show that $\mathcal{I}_n(2\text{–}3\text{–}1)$ is counted by 2^{n-1}.

Proposition 6. *The number of involutions of* $[n]$ *that avoid* (2–3–1) *is* 2^{n-1}.

We give a general description of the elements of $\mathcal{I}_n(2\text{–}3\text{–}1)$. Note that, if $\pi = a_1a_2\cdots a_n$ is a permutation of $[n]$, where n is in position k, then π avoids (2–3–1) if and only if it can be written as $\pi = \sigma n\tau$, where $\sigma = a_1a_2\cdots a_{k-1}$ is a (2–3–1)-avoiding permutation of $[k-1]$ and $\tau = a_{k+1}a_{k+2}\cdots a_n$ is a (2–3–1)-avoiding permutation of $\{k,\dots n-1\}$. Furthermore, if π is an involution we see that since n is in position k, the letter k must be in position n, and the only (2–3–1)-avoiding permutation τ of $\{k,\dots n-1\}$ ending with k is $\tau = (n-1)(n-2)\cdots(k+1)k$, that is, these letters must be in decreasing order. Indeed, all other possible τ's will contain at least one ascent ij, where $i<j$, and ijk will then form a (2–3–1)-subword. Hence every π in $\mathcal{I}_n(2\text{–}3\text{–}1)$ is of the form $\sigma n(n-1)\cdots(k+1)k$ where σ is in $\mathcal{I}_{k-1}(2\text{–}3\text{–}1)$. Such a π can be written explicitly as

$$\pi = k_1\cdots 1k_2\cdots(k_1+1)k_3\cdots(k_{\ell-1}+1)n\cdots(k_\ell+1).$$

In other words, the involutions can be considered as divided into segments, such that

(a) each letter in segment i is smaller than every letter in segment $(i+1)$,
(b) the elements in each segment are in decreasing order.

In order to show that $|\mathcal{I}_n(2\text{-}3\text{-}1)| = 2^{n-1}$ we give four proofs, where we construct bijections from $\mathcal{I}_n(2\text{-}3\text{-}1)$ to different sets that are known to be counted by 2^{n-1}.

First proof. Let B_n be the collection of binary strings of length n. Given a binary string $x = x_1x_2\cdots x_{n-1}$ in B_{n-1}, a permutation $\pi = a_1a_2\cdots a_n$ in $\mathcal{S}_n$ is constructed inductively by letting $\pi_0 = 1$ and then, if $\pi_i = \sigma i\tau$, by letting

$$\begin{aligned} \pi_{i+1} &= \sigma i\tau(i+1), \text{ if } x_i = 0 \\ \pi_{i+1} &= \sigma i(i+1)\tau, \text{ if } x_i = 1. \end{aligned}$$

That is, the permutation π is built up by successively placing each of the elements $1,\ldots,n$ either as the last element or just before the largest element already placed. This procedure defines a mapping

$$\begin{aligned} \Phi_n : B_{n-1} &\to \mathcal{S}_n, \\ x &\mapsto \pi. \end{aligned}$$

Denote the image of B_{n-1} by A_n. Then A_n consists of all permutations of the form

$$\sigma n(n\text{-}1)(n\text{-}2)\ldots(k+1)k, \text{ where } \sigma \in A_{k-1},$$

and is easily seen to coincide with $\mathcal{I}_n(2\text{-}3\text{-}1)$, according to the description above. Since Φ_n is clearly injective we have a one-to-one correspondence between the binary strings of length $(n-1)$ and $\mathcal{I}_n(2\text{-}3\text{-}1)$, hence $|\mathcal{I}_n(2\text{-}3\text{-}1)| = |B_{n-1}| = 2^{n-1}$. □

Example 7. Consider the binary string $x = 010111 \in B_6$. Then Φ_7 maps x to $\pi = 1327654$, via π_i, for $i = 0,\ldots,6$, where

$$\begin{aligned} \pi_0 &= 1 \\ \pi_1 &= 12, \text{ since } x_1 = 0 \\ \pi_2 &= 132, \text{ since } x_2 = 1 \\ \pi_3 &= 1324, \text{ since } x_3 = 0 \\ \pi_4 &= 13254, \text{ since } x_4 = 1 \\ \pi_5 &= 132654, \text{ since } x_5 = 1 \\ \pi = \pi_6 &= 1327654, \text{ since } x_6 = 1. \end{aligned}$$

Second proof. In this proof we show the one-to-one correspondence between $\mathcal{I}_n(2\text{-}3\text{-}1)$ and the binary strings of length $(n-1)$ by constructing

a mapping Ψ_n from T_n to B_{n-1}. Here T_n is the set of inversion tables $t = (t_1, t_2, \ldots, t_n)$ defined from $\pi = a_1 a_2 \cdots a_n \in \mathcal{I}_n(2\text{–}3\text{–}1)$ as

$$t_i := |\{j : j > i, a_j < a_i\}|.$$

That is, the ith entry of t is the number of letters following the ith letter of π that are smaller than the ith letter. From the appearance of $\mathcal{I}_n(2\text{–}3\text{–}1)$ it follows that the elements in T_n will be of the form

$$(k_1, k_1 - 1, \ldots, 1, 0, \ldots, 0, k_2, k_2 - 1, \ldots, 1, 0, k_\ell, k_\ell - 1, \ldots, 1, 0).$$

For example, a decreasing sequence $a_i a_{i+1} \ldots a_{i+k}$ of length $(k+1)$ will give rise to the segment $(t_i, t_{i+1}, \ldots, t_{i+k}) = (k, (k-1), \ldots, 1, 0)$ in the corresponding inversion table $t(\pi)$.

The mapping

$$\begin{array}{rcl} \Psi_n : T_n & \to & B_{n-1} \\ t = (t_1, t_2, \ldots, t_n) & \mapsto & x = x_1 x_2 \cdots x_{n-1} \end{array}$$

is now defined by

$$x_i = \begin{cases} 0 \text{ if } t_i = 0, \\ 1 \text{ if } t_i \neq 0. \end{cases}$$

It is easy to see that Ψ_n is invertible, when restricted to (2–3–1)-avoiding involutions. The inverse mapping is given by

$$t_i = \begin{cases} 0, \text{ if } x_i = 0, \\ s, \text{ where } (s-1) \text{ is the number of 1's following } x_i, \text{ if } x_i = 1. \end{cases}$$

A permutation is uniquely determined by its inversion table. Hence there is a one-to-one correspondence between B_{n-1} and $\mathcal{I}_n(2\text{–}3\text{–}1)$ via the inversion tables $\{T_n\}$, and $|\mathcal{I}_n(2\text{–}3\text{–}1)| = 2^{n-1}$. □

Example 8. Consider $\pi = 1327654$ from Example 7. The corresponding inversion table is $t = (0, 1, 0, 3, 2, 1, 0)$, according to Example 4. Now Ψ_7 maps $(0, 1, 0, 3, 2, 1, 0)$ onto 0101110, which is exactly the binary string x, given by the mapping Φ_7 in the first proof.

Third proof. Denote the set of subsets of $[n]$ by $\mathcal{P}_n$. We construct π in $\mathcal{I}_n(2\text{–}3\text{–}1)$ from A in $\mathcal{P}_{n-1}$ by letting the letter i be immediately preceded by a larger letter, if and only if i is in A. Because of the appearance of the elements in $\mathcal{I}_n(2\text{–}3\text{–}1)$ there is only one choice of the larger letter to precede i, namely $(i+1)$, and this algorithm for constructing π from A therefore clearly defines a bijection. Indeed, the segment $(i+k)(i+k-1)\cdots i$ is contained in π if and only if i, $(i+1)$, …, $(i+k)$ are in A. Hence there is a one-to-one correspondence between $\mathcal{P}_{n-1}$ and $\mathcal{I}_n(2\text{–}3\text{–}1)$, so $|\mathcal{I}_n(2\text{–}3\text{–}1)| = |\mathcal{P}_{n-1}| = 2^{n-1}$. □

Example 9. Let $A = \{2, 4, 5, 6\}$. The corresponding π is 1327654. Indeed, the letter 2 is the smallest letter that is in A, and accordingly the smallest letter to be preceded by a larger letter. From this we conclude

that 1 is a fixed point and, since 3 is not in A, the decreasing sequence ending with 2 must start with 3. The letter 4 is in A as well as 5 and 6, and hence π must contain the segment 7654.

We also see from this example how to get from π to A. Considering $\pi = 1327654$ we find that exactly the letters 2, 4, 5 and 6 are preceded by larger letters, hence $A = \{2, 4, 5, 6\}$.

Porism 10. *The number of involutions in $\mathcal{I}_n(2\text{-}3\text{-}1)$ with exactly k descents is $\binom{n-1}{k}$.*

Proof. Consider the bijection from $\mathcal{P}_{n-1}$ to $\mathcal{I}_n(2\text{-}3\text{-}1)$ defined in the third proof above. A (2-3-1)-avoiding involution is constructed from A in $\mathcal{P}_{n-1}$ by letting i be preceded by a larger letter if and only if i is in A. Hence the number of elements in A counts the descents of π. Since there are $\binom{n-1}{k}$ ways of choosing k letters out of $[n-1]$, the result follows. □

Finally, we give a proof by showing a one-to-one correspondence between $\mathcal{I}_n(2\text{-}3\text{-}1)$ and a certain type of Dyck paths, that are easily counted.

Fourth proof (of Proposition 6). Claesson [1] gives a proof of the well-known result that $\mathcal{S}_n(2\text{-}1\text{-}3)$ is counted by the nth Catalan number, in which he defines recursively a bijective mapping Φ from $\mathcal{S}_n(2\text{-}1\text{-}3)$ to the set of Dyck paths of length $2n$. We mimic his proof and construct a mapping Φ from $\mathcal{S}_n(2\text{-}3\text{-}1)$ to the Dyck paths of length $2n$.

Consider $\pi = a_1 a_2 \cdots a_n$ in $\mathcal{S}_n(2\text{-}3\text{-}1)$ with the letter n in position k. According to the discussion on page 6 we can write $\pi = \sigma n \tau$, where $\sigma = a_1 a_2 \cdots a_{k-1}$ is a (2-3-1)-avoiding permutation of $[k-1]$ and $\tau = a_{k+1} a_{k+2} \cdots a_n$ is a (2-3-1)-avoiding permutation of $\{k+1, k+2, \ldots, n-1\}$.

Denoting the empty word by ϵ, we define $\Phi(\pi)$ recursively by

$$\Phi(\pi) = \begin{cases} \epsilon, \text{ if } \pi = \epsilon, \\ u\,(\Phi \circ \mathrm{proj})(\sigma)\,d\,(\Phi \circ \mathrm{proj})(\tau), \text{ otherwise.} \end{cases}$$

Here, $\mathrm{proj}(x)$ denotes the *projection* of the word $x = x_1 x_2 \cdots x_n$, where $x_i \in \mathbb{N}$ and $x_i \neq x_j$, onto $\mathcal{S}_n$, defined by

$$\mathrm{proj}(x) = a_1 a_2 \cdots a_n, \text{ where } a_i = |\{j \in [n].x_i \geq x_j\}|.$$

For example $\mathrm{proj}(265) = 132$.

It is easy to see that Φ is invertible and hence a bijection.

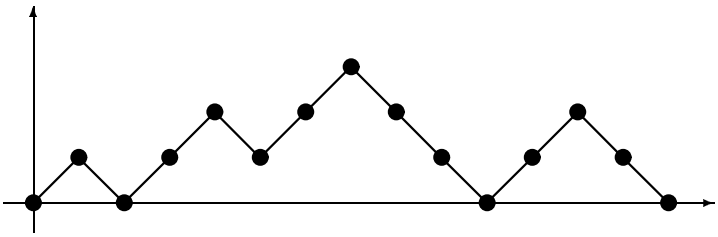

FIGURE 2. The Dyck path in Example 11

Example 11. Consider $\pi = 7312645 \in \mathcal{S}_7(2\text{-}3\text{-}1)$. The corresponding Dyck path is given by:

$$\begin{aligned}
\Phi(\pi) &= u\Phi(\epsilon)d\Phi(312645)\\
&= u\epsilon du\Phi(312)d\Phi(12)\\
&= u\epsilon duu\Phi(\epsilon)d\Phi(12)du\Phi(1)d\Phi(\epsilon)\\
&= u\epsilon duu\epsilon du\Phi(1)d\Phi(\epsilon)duu\Phi(\epsilon)d\Phi(\epsilon)d\epsilon\\
&= u\epsilon duu\epsilon duu\Phi(\epsilon)d\epsilon d\epsilon duu\epsilon d\epsilon d\epsilon\\
&= u\epsilon duu\epsilon duu\epsilon d\epsilon d\epsilon duu\epsilon d\epsilon d\epsilon\\
&= uduuduuddduudd.
\end{aligned}$$

When restricted to involutions we have that τ, and accordingly $\Phi(\tau)$, is determined by the position of n. In fact, the decreasing sequence starting with n, that is $n\tau$, where $\tau = (n-1)\cdots k$, corresponds to the Dyck path

$$\begin{aligned}
\Phi(\tau) &= u\Phi(\epsilon)d\Phi((n-1)(n-2)\cdots k)\\
&= udu\Phi(\epsilon)d\Phi((n-2)(n-3)\cdots k)\\
&\vdots\\
&= udud\cdots ud.
\end{aligned}$$

The image of $\mathcal{I}_n(2\text{-}3\text{-}1)$, denoted by D_n^*, will therefore be

$$D_n^* = \{uD_{n-k}^* dud\cdots ud\}.$$

That is, a Dyck path in D_n^* ends with a tail of the form $udud\cdots ud$, preceding which, there are no returns to the x-axis. Removing the tail, the down-step just before it and the first up-step of the Dyck path yields a path with the same properties. Note that D_n^* is the set of Dyck paths, in which a down-step is immediately followed by at most one up-step. As a consequence the peaks as well as the valleys are of decreasing height. An illustration of a typical Dyck path in D_n^* is given in Example 12 below.

From the construction, the number of D_n^* satisfies the recursion

$$|D_n^*| = \sum_{i=1}^{n-1} |D_i^*|,$$

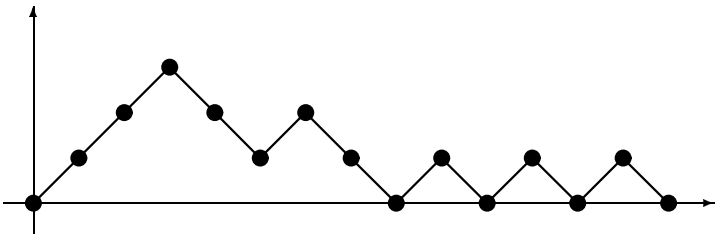

FIGURE 3. The Dyck path in Example 12

and since $D_1^* = \{ud\}$, we have $|D_1^*| = 1$, so $|D_n^*| = 2^{n-1}$. □

Example 12. Let us return to the (2-3-1)-avoiding involution $\pi = 1327654$ from Example 7. We have that π corresponds to the Dyck path:

$$\begin{aligned}
\Phi(\pi) &= u\Phi(132)d\Phi(321) \\
&= uu\Phi(1)d\Phi(1)du\Phi(\epsilon)d\Phi(21) \\
&= uuu\Phi(\epsilon)ddu\Phi(\epsilon)ddu\epsilon du\Phi(\epsilon)d\Phi(1) \\
&= uuu\epsilon ddu\epsilon ddu\epsilon du\epsilon du\Phi(\epsilon)d\Phi(\epsilon) \\
&= uuu\epsilon ddu\epsilon ddu\epsilon du\epsilon du\epsilon d\epsilon \\
&= uuudduddududdud.
\end{aligned}$$

Proposition 13. *The number of involutions of* $[n]$ *that avoid* (3-1-2) *is* 2^{n-1}.

For the proof we need the following lemma.

Lemma 1. *Let* p *be a pattern in* $\mathcal{S}_k$. *Then* $\mathcal{I}_n(p) = \mathcal{I}_n(p^{-1})$.

Proof. Consider the involution π written in two line notation;

$$\pi = \begin{pmatrix} 1 & 2 & \dots & n \\ a_1 & a_2 & \dots & a_n \end{pmatrix}.$$

Suppose that the subword

$$v = \begin{pmatrix} i_1 & i_2 & \dots & i_k \\ a_{1_1} & a_{i_2} & \dots & a_{i_n} \end{pmatrix}$$

forms an occurrence of p. Then

$$v^{-1} = \begin{pmatrix} a_{1_1} & a_{i_2} & \dots & a_{i_n} \\ i_1 & i_2 & \dots & i_k \end{pmatrix}$$

is a p^{-1}-subword, contained in

$$\pi^{-1} = \begin{pmatrix} a_1 & a_2 & \dots & a_n \\ 1 & 2 & \dots & n \end{pmatrix}.$$

But since π is an involution, we have that $\pi = \pi^{-1}$, so π contains also the p^{-1}-subword v^{-1}. Hence we have an occurrence of p^{-1} if and only if we have an occurrence of p. □

Example 14. Let p be the pattern

$$p = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 1 & 3 \end{pmatrix}.$$

Then

$$q = p^{-1} = \begin{pmatrix} 2 & 4 & 1 & 3 \\ 1 & 2 & 3 & 4 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 2 \end{pmatrix}$$

is the inverse of p. Let π be the involution

$$\pi = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ 5 & 3 & 2 & 9 & 1 & 6 & 8 & 7 & 4 \end{pmatrix}.$$

The letters

$$v = \begin{pmatrix} 2 & 4 & 5 & 8 \\ 3 & 9 & 1 & 7 \end{pmatrix}$$

form an occurrence of the pattern p. Accordingly,

$$v^{-1} = \begin{pmatrix} 3 & 9 & 1 & 7 \\ 2 & 4 & 5 & 8 \end{pmatrix} = \begin{pmatrix} 1 & 3 & 7 & 9 \\ 5 & 2 & 8 & 4 \end{pmatrix}$$

forms a q-subword.

Proof of Proposition 13. We have that (3-1-2) is the inverse of (2-3-1). The result then follows immediately from Proposition 6 and Lemma 1. □

We conclude this section by an application of Proposition 6 to a certain set of pattern avoiding permutations. Claesson [1] shows that involutions of $[n]$ are in one-to-one correspondence with permutations of $[n]$ that avoid (1-23) and (1-32). For the proof he constructs a bijection Φ between $\mathcal{I}_n$ and $\mathcal{S}_n(1\text{-}23, 1\text{-}32)$, which we describe below.

The standard form of a permutation π is defined by writing π in cycle notation and requiring that

(a) each cycle is written with its least element first
(b) the cycles are written in decreasing order with respect to their first elements.

The corresponding permutation $\widehat{\pi} = \Phi(\pi)$ is obtained from π in standard form by erasing the brackets separating the cycles. Since involutions consist of cycles of length one or two, each permutation $\widehat{\pi}$ in $\mathcal{S}_n(1\text{-}23, 1\text{-}32)$ is obtained from exactly one involution, and Φ is therefore a bijection.

Corollary 15. *Involutions of* $[n]$ *that avoid* (2-3-1) *are in one-to-one correspondence with permutations in* $[n]$ *that avoid* (1-23), (1-32), (13-2) *and* (3-214). *Hence*

$$|\mathcal{S}_n(1\text{-}23, 1\text{-}32, 13\text{-}2, 3\text{-}214)| = |\mathcal{I}_n(2\text{-}3\text{-}1)| = 2^{n-1}.$$

Proof. Claesson [1] proves the one-to-one correspondence between $\mathcal{S}_n(1\text{–}23, 1\text{–}32)$ and $\mathcal{I}_n$, so what is left to prove is that, given a (2–3–1)-avoiding involution π we have that $\Phi(\pi)$ avoids (13–2) and (3–214) and vice versa.

To show that $\Phi(I_n(2-3-1)) \subseteq S_n(1-23, 1-32, 13-2, 3-214)$, assume that $\widehat{\pi}$ in $\mathcal{S}_n(1\text{–}23, 1\text{–}32)$ contains a (13–2)-subword. Then there exists a segment of $\widehat{\pi}$ of the form

$$a_1 a_3 \cdots a_2, \quad \text{where } a_1 < a_2 < a_3.$$

Since the cycles of involutions in standard form are of maximum length two and are written with their least element first, $\widehat{\pi}$ necessarily corresponds to an involution π containing the cycle (a_1, a_3). It also follows that the letter a_2 must be contained in a cycle $(\tilde{a}, a_2)$, where $\tilde{a} < a_1$, for otherwise a_2 would precede a_1 in $\widehat{\pi}$. We now have that

$$a_2 \cdots a_3 \cdots \tilde{a} \cdots a_1, \quad \text{where } \tilde{a} < a_1 < a_2 < a_3,$$

is a segment of π, so π contains the (2–3–1)-subword $a_2 a_3 a_1$.

Assume instead that $\widehat{\pi}$ has an occurrence of (3–214), that is $\widehat{\pi}$ contains the segment

$$a_3 \cdots a_2 a_1 a_4, \quad \text{where } a_1 < a_2 < a_3 < a_4.$$

Then $(a_1 a_4)$ must be a 2-cycle of π. The letters a_2 and a_3 can either be fixed points or contained in 2-cycles.

Assuming that a_2 and a_3 both are fixed points implies that π contains a segment of the form

$$a_4 \cdots a_2 \cdots a_3 \cdots a_1, \quad \text{where } a_1 < a_2 < a_3 < a_4.$$

Here $a_2 a_3 a_1$ forms a (2–3–1)-subword.

If a_3 is a fixed point while a_2 is not, then a_2 will be contained in a cycle $(\tilde{a_2}, a_2)$ where $a_1 < \tilde{a_2} < a_2$, once again resulting in the (2–3–1)-subword $a_2 a_3 a_1$ of π.

Finally we assume that a_3 is contained in a 2-cycle $(\tilde{a_3}, a_3)$, where $\tilde{a_3} > a_2$ (or $\tilde{a_3} > \tilde{a_2}$, if there is a cycle $(\tilde{a_2}, a_2)$). We then get the following possible segments of π:

$$\begin{aligned}
&a_4 \cdots a_2 \cdots \tilde{a_2} \cdots a_3 \cdots \tilde{a_3} \ldots a_1, \text{ where } \tilde{a_3} < a_3,\\
&a_4 \cdots a_2 \cdots \tilde{a_2} \cdots \tilde{a_3} \cdots a_3 \ldots a_1, \text{ where } a_3 < \tilde{a_3} < a_4,\\
&a_4 \cdots a_2 \cdots \tilde{a_2} \cdots \tilde{a_3} \cdots a_1 \ldots a_3, \text{ where } \tilde{a_3} > a_4.
\end{aligned}$$

In all cases we get an occurrence of (2–3–1). Hence it follows that

$$\Phi(I_n(2-3-1)) \subseteq S_n(1-23, 1-32, 13-2, 3-214).$$

To show the converse, that is

$$\mathcal{S}_n(1-23, 1-32, 13-2, 3-214) \subseteq \Phi(I_n(2-3-1)),$$

we consider $\pi \in I_n(2\text{-}3\text{-}1)$. There are essentially two different ways of constructing a (2-3-1)-subword out of three letters a_1, a_2 and $a_3 \in [n]$ such that $a_1 < a_2 < a_3$. Either we get an involution of the form

$$\dots (a_3 b_3) \dots (a_2 b_2) \dots (a_1 b_1) \dots,$$

where

$$a_1 < a_2 < a_3,\ b_2 < b_3 < b_1,\ a_1 < b_1$$

or an involution of the form

$$\dots (b_2 a_2) \dots (b_3 a_3) \dots (a_1 b_1) \dots$$

where

$$a_1 < a_2 < a_3,\ b_2 < b_3 < b_1,\ a_2 > b_2,\ a_3 > b_3.$$

Consider the first case. Without loss of generality we let $a_3 \leq b_3$ and $a_2 \leq b_2$. The special cases when a_2 and a_3 are fixed points are given by letting a_2 and a_3 be equal to b_2 and b_3 respectively. Consider the cycle $(ij) = (b_1 a_1)$. Clearly $i < j$. Let $(k\ell)$ be the cycle to the left of (ij) ($k = \ell$ denotes the case when k is a fixed point). If $\ell < j = b_3$, then ℓij forms a (3-214)-subword of the corresponding permutation $\Phi(\pi)$, because ℓ is clearly larger than i. Otherwise let $(ij) = (k\ell)$ and repeat the above arguments until a (3-214)-subword is obtained. This is guaranteed to happen, since if we have gone through all cycles between $(b_2 a_2)$ and $(b_1 a_1)$, then with b_2 as ℓ we have that $\ell = b_2 < b_3$.

Considering the second case, without loss of generality we let $a_1 \leq b$. The case when a_1 is a fixed point is denoted by $a_1 = b_1$. The subword $(b_2 a_2 a_1)$ will now form an occurrence of (13-2) since $b_2 < a_1 < a_2$.

This proves that

$$S_n(1-23, 1-32, 13-2, 3-214) \subseteq \Phi(I_n(2-3-1)).$$

Hence

$$|S_n(1-23, 1-32, 13-2, 3-214)| = |(I_n(2-3-1)|.$$

□

3.2. **Avoiding (2-1-3) or (1-3-2).** We introduce a couple of results that will be used in the proof of Proposition 18. First we present a well-known property of the patterns in $\mathcal{S}_3$.

Proposition 16. *Let p be a pattern in $\mathcal{S}_3$. Then $|\mathcal{S}_3(p)| = C_n$, where $C_n = \frac{1}{n+1}\binom{2n}{n}$ is the nth Catalan number.*

One way of proving Proposition 16 is to construct a bijection between the pattern avoiding permutations of $[n]$ and the set of Dyck paths of length $2n$, that are known to be counted by the nth Catalan number. Such a bijection for the case when $p = (2\text{-}3\text{-}1)$ is actually presented in the fourth proof of Proposition 6 on page 9.

Next we consider a consequence of the fact that an involution is its own inverse.

Lemma 2. *Let p be an involution of $[k]$ and π a permutation of $[n]$. Then π avoids the pattern p if and only if π^{-1} avoids p.*

Proof. Consider π written in two line notation:

$$\pi = \begin{pmatrix} 1 & 2 & \dots & n \\ a_1 & a_2 & \dots & a_n \end{pmatrix}.$$

Suppose that we have an occurrence of p as the subword

$$v = \begin{pmatrix} i_1 & i_2 & \dots & i_k \\ a_{1_1} & a_{i_2} & \dots & a_{i_n} \end{pmatrix}.$$

Since p is an involution, we have that $p^{-1} = p$ and

$$v^{-1} = \begin{pmatrix} a_{1_1} & a_{i_2} & \dots & a_{i_n} \\ i_1 & i_2 & \dots & i_k \end{pmatrix}$$

forms a p-subword contained in

$$\pi^{-1} = \begin{pmatrix} a_1 & a_2 & \dots & a_n \\ 1 & 2 & \dots & n \end{pmatrix}.$$

Hence π avoids p if and only if π^{-1} avoids p. □

Example 17. Let p be the 5-pattern

$$p = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 1 & 4 & 2 \end{pmatrix}.$$

Clearly p is an involution. Now consider the permutation

$$\pi = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ 5 & 4 & 9 & 1 & 2 & 6 & 7 & 3 & 8 \end{pmatrix}.$$

The subword

$$v = \begin{pmatrix} 1 & 3 & 5 & 7 & 8 \\ 5 & 9 & 2 & 7 & 3 \end{pmatrix}$$

forms an occurrence of p and accordingly

$$\pi^{-1} = \begin{pmatrix} 5 & 4 & 9 & 1 & 2 & 6 & 7 & 3 & 8 \\ 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ 4 & 5 & 8 & 2 & 1 & 6 & 7 & 9 & 3 \end{pmatrix},$$

contains the p-subword

$$v = \begin{pmatrix} 5 & 9 & 2 & 7 & 3 \\ 1 & 3 & 5 & 7 & 8 \end{pmatrix} = \begin{pmatrix} 2 & 3 & 5 & 7 & 9 \\ 5 & 8 & 1 & 7 & 3 \end{pmatrix}.$$

Proposition 18. *The number of involutions of $[n]$ that avoid (2-1-3) is the nth central binomial coefficient $\binom{n}{n/2}$.*

Proof. First we give a general description of the elements in $\mathcal{I}_n(2\text{-}1\text{-}3)$. If $\pi = a_1a_2\cdots a_n$ is a permutation of $[n]$ with the letter 1 in position k, then π avoids (2-1-3) if and only if it can be written as $\pi = \sigma 1 \tau$, where $\sigma = a_1a_2\cdots a_{k-1}$ is a (2-1-3)-avoiding permutation of $\{n, (n-1), \ldots, (n-k+2)\}$ and $\tau = a_{k+1}a_{k+2}\cdots a_n$ is a (2-1-3)-avoiding permutation of $\{2, 3, \ldots, (n-k+1)\}$. That is, the letters preceding 1 must all be larger than the ones following 1, and clearly all segments of π must be (2-1-3)-avoiding.

When constructing a (2-1-3)-avoiding involution, π, there are essentially two different ways of positioning the letter 1. Either it can be placed as the first letter a_1, in which case $\sigma = \epsilon$, the empty word, or it can be placed in the second half of the word, that is in position k where $k \geq \frac{n}{2}+1$. Namely, σ, if nonempty, consists of the $(k-1)$ largest letters of $[n]$, in particular k, that is the first letter of π, because 1 is the kth letter, must be one of the $(k-1)$ largest letters, so $k \geq \frac{n}{2}+1$.

Let us now consider the permutation τ. In the first case, when 1 is a fixed point, τ is merely a (2-1-3)-avoiding involution of $\{2, 3, \ldots, n\}$. In the second case though, the letters following 1, in positions larger than k, will all be smaller than k, so an arbitrary permutation of $\{2, 3, \ldots, (n-k+1)\}$ will do as τ as long as it avoids (2-1-3). We notice that the first $(n-k+1)$ letters of π are uniquely determined by τ since the letters of τ must all be contained in 2-cycles (i, a_i), where $i \leq (n-k+1)$. Hence $\pi = a_1a_2\cdots a_n$ can be written as

$$\pi = k\tau^{-1}\rho 1\tau,$$

where τ^{-1} is the inverse of τ seen as a bijection from $\{2, 3, \ldots, (n-k+1)\}$ to $\{k, (k+1), \ldots n\}$ and where $\rho = a_{n-k+2}a_{n-k+3}\cdots a_{k-1}$. To make sure that π is (2-1-3)-avoiding we must check that τ^{-1} avoids (2-1-3) whenever τ does, but this is exactly what is said in Lemma 2. Finally ρ, must be a (2-1-3)-avoiding involution of $\{(n-k+2), (n-k+1), \ldots, (k-1)\}$, on which we recursively repeat the arguments above.

The next step of the proof is to derive an expression for the number of (2-1-3)-avoiding involutions from the above description of them. Let, for the sake of simplicity, $|\mathcal{I}_n(2\text{-}1\text{-}3)|$ be denoted by A_n. With 1 in position k, where $k \geq \frac{n}{2}+1$, the number of possible τ's is the $(n-k)$th Catalan number C_{n-k}, according to Proposition 16. Independently of τ there are A_{2k-n-2} ways of choosing ρ, so the number of (2-1-3)-avoiding involutions with $a_k = 1$ is $A_{2k-n-2}C_{n-k}$. Moreover, there are A_{n-1} possible (2-1-3)-avoiding involutions with 1 as a fixed point. Thus

$$A_n = A_{n-1} + \sum_{k=\lfloor \frac{n}{2} \rfloor + 1}^{n} A_{2k-n-2}C_{n-k}$$

and $A_n = 0$ if $n \leq 0$. This recursion is satisfied by the central binomial coefficients [11], thus we conclude that $|\mathcal{I}_n(2\text{-}1\text{-}3)| = A_n = \binom{n}{n/2}$. $\square$

We now turn to avoidance of (1-3-2). For this purpose we introduce the trivial bijections on permutations.

3.2.1. *Trivial bijections.* Let $\pi = a_1 a_2 \cdots a_n \in \mathcal{S}_n$. We define the *reverse* of π as $R(\pi) := a_n \cdots a_2 a_1$, and the *complement* of π by $C(\pi)(i) = n + 1 - \pi(i)$, where $i \in [n]$. These bijections from $\mathcal{S}_n$ to itself and their composition $C \circ R$ are called *trivial*. Let Φ be a trivial bijection and let π be in $\mathcal{S}_n(p)$. Then the permutation $\Phi(\pi)$ avoids the pattern $\Phi(p)$ and consequently the number of permutations avoiding $R(p)$, $C(p)$ or $R \circ P(p)$ is the same as the number of permutations avoiding the pattern p. Note that the reverse of the generalised pattern $(a_1\text{-}a_2a_3\text{-}a_4a_5)$ is $(a_5a_4\text{-}a_3a_2\text{-}a_1)$. Also the dashes are "reversed".

Example 19. Let $p = 534621$. It is clear that p avoids (1-3-2). The reverse of π, $R(\pi) = 125435$, the complement of π, $C(\pi) = 243156$ and their composition, $R \circ C(\pi) = 651342$ then avoid $R(p) = (2\text{-}3\text{-}1)$, $C(p) = (3\text{-}1\text{-}2)$ and $R \circ C(p) = (2\text{-}1\text{-}3)$, respectively.

Lemma 3. *The composition $C \circ R$, restricted to $\mathcal{I}_n$, is a bijection from $\mathcal{I}_n$ to itself.*

Proof. Let π be in $\mathcal{I}_n$. Then π consists of cycles of length 1 and 2, that is, $\pi(j) = k$ whenever $\pi(k) = j$. The case when j is a fixed point is denoted by $k = j$. Let (j, k) be a cycle of π, then

$$\begin{aligned} R(\pi)(n+1-j) &= \pi(n+1-(n+1-j)) = \pi(j) = k, \\ C \circ R(\pi)(n+1-j) &= n+1-R(\pi)(n+1-j) = n+1-k. \end{aligned}$$

Likewise $C \circ R(\pi)(n+1-k) = n+1-j$ which shows that $(n+1-j,$ $n+1-k)$ is a 2-cycle of $C \circ R(\pi)$. Hence $C \circ R(\pi)$ is an involution, so $C \circ R(\mathcal{I}_n) = \mathcal{I}_n$. □

Proposition 20. *The number of involutions of $[n]$ that avoid (1-3-2) is the nth central binomial coefficient $\binom{n}{n/2}$.*

Proof. Let π be in $\mathcal{I}_n(2\text{-}1\text{-}3)$. The permutation $C \circ R(\pi)$ is in $\mathcal{I}_n$ by Lemma 3 and it is clear from above that $C \circ R(\pi)$ avoids $C \circ R(2\text{-}1\text{-}3) = (1\text{-}3\text{-}2)$. Since $C \circ R$ is a bijection from $\mathcal{I}_n$ to $\mathcal{I}_n$ it follows that

$$C \circ R : \mathcal{I}_n(2\text{-}1\text{-}3) \to \mathcal{I}_n(1\text{-}3\text{-}2)$$

is injective, thus $|\mathcal{I}_n(2\text{-}1\text{-}3)| \leq |\mathcal{I}_n(1\text{-}3\text{-}2)|$. In order to show the converse, note that $C \circ R$ is its own inverse and hence $C \circ R(C \circ R(p)) = p$. An application of the same argument to $C \circ R(2\text{-}1\text{-}3) = (1\text{-}3\text{-}2)$ implies the desired inequality $|\mathcal{I}_n(1\text{-}3\text{-}2)| \leq |\mathcal{I}_n(2\text{-}1\text{-}3)|$. Thus, it follows that $|\mathcal{I}_n(2\text{-}1\text{-}3)| = |\mathcal{I}_n(1\text{-}3\text{-}2)|$. □

3.3. **Avoiding p, when p is an increasing or decreasing sequence.** This section concerns avoidance of to the two remaining 3-patterns, (1–2–3) and (3–2–1). Although we have not found any direct relation between $\mathcal{I}_n(1\text{–}2\text{–}3)$ and $\mathcal{I}_n(3\text{–}2\text{–}1)$, it is possible to give almost analogous proofs for them being counted by $\binom{n}{n/2}$ by using the RSK algorithm for Young Tableaux, as will be seen below. We start however with a combinatorial proof for (3–2–1)-avoidance, based on work by Kitaev and Claesson.

In Kitaev [5], which concerns multiavoidance of 3-patterns without internal dashes, it is shown that the permutations of $[n]$ that simultaneously avoid (123), (132) and (213) are counted by the central binomial coefficients. We will use this result to conclude that the number of (3–2–1)-avoiding involutions of $[n]$ is $\binom{n}{n/2}$. Thus we have to establish a relation between $\mathcal{I}_n(3\text{–}2\text{–}1)$ and $\mathcal{S}_n(123, 132, 213)$.

Lemma 4. *Involutions of* $[n]$ *that avoid* (3–2–1) *are in one-to-one correspondence with permutations of* $[n]$ *that avoid* (123), (132) *and* (213). *Hence*

$$|\mathcal{I}_n(3\text{–}2\text{–}1)| = |\mathcal{S}_n(123, 132, 213)|.$$

Proof. Claesson [1] gives a proof that there is a one-to-one correspondence between $\mathcal{I}_n$ and $\mathcal{S}_n(1\text{–}23, 1\text{–}32)$ by constructing the bijection Φ, which is described in connection to Corollary 15, on page 12. Furthermore, he observes that the dashes in the patterns are immaterial for the proof and accordingly $\mathcal{S}_n(123, 132) = \mathcal{S}_n(1\text{–}23, 1\text{–}32)$. We show that Φ restricted to the (3–2–1)-avoiding involutions gives exactly the permutations that avoid (123), (132) and (213).

To show that $\mathcal{S}_n(123, 132, 213) \subseteq \Phi(\mathcal{I}_n(3\text{–}2\text{–}1))$, let π be an involution of $[n]$ and let $\widehat{\pi}$ be the corresponding permutation in $\mathcal{S}_n(123, 132)$. Assume that $\widehat{\pi}$ contains a (213)-subword. There then exists a segment of $\widehat{\pi}$ of the form

$$a_2 a_1 a_3, \text{ where } a_1 < a_2 < a_3.$$

Since the cycles in the standard form are of maximum length two and are written in decreasing order with their least elements first, the only possibility for a_3 to follow a_1 is that (a_1, a_3) is a cycle of π. The letter a_2 is either a fixed point or contained in the 2-cycle $(\widetilde{a_2}, a_2)$, where $a_1 < \widetilde{a_2} < a_2$. Thus π contains either the segment

$$a_3 \cdots a_2 \cdots a_1, \text{ where } a_1 < a_2 < a_3$$

or

$$a_3 \cdots \tilde{a_2} \cdots a_2 \cdots a_1, \text{ where } a_1 < \tilde{a_2} < a_2 < a_3,$$

where $a_3 a_2 a_1$ forms a (3–2–1)-subword in both cases.

In order to show that $\Phi(\mathcal{I}_n(3\text{–}2\text{–}1)) \subseteq \mathcal{S}_n(123, 132, 213)$ we assume that there is an occurrence of (3–2–1) in π, that is, π contains a segment

$$a_3 \cdots a_2 \cdots a_1, \text{ where } a_1 < a_2 < a_3.$$

There are essentially three different ways of constructing this out of a_1, a_2 and a_3.

First, we consider the case when π, written in cycle notation, is of the form

$$\cdots (a_1 b_1) \cdots (b_2 a_2) \cdots (b_3 a_3) \cdots,$$

where

$$a_1 < a_2 < a_3 \text{ and } b_3 < b_2 < b_1.$$

Let $a_1 = b_1$ denote the case when a_1 is a fixed point. Consider the cycle $(ij) = (b_3 a_3)$. Clearly $i < j$. Let $(k\ell)$ be the cycle to the left of (ij) ($k = \ell$ denotes the case when k is a fixed point). If $\ell < j = a_3$, then ℓij forms a (213)-subword of the corresponding permutation $\Phi(\pi)$. Otherwise let $(ij) = (k\ell)$ and repeat the above reasoning. We realize that this procedure will cause a (213)-subword to be formed as ℓij. Indeed, if we have gone through all cycles between a_2 and b_3, then with a_2 as ℓ it will be true that $i < \ell < j$, because ℓ is smaller than j ($j \geq a_3 > a_2 = \ell$) and since the cycles are written in decreasing order it follows that ℓ is larger than i.

The next possibility is that π is of the form

$$\cdots (a_1 b_1) \cdots (a_2 b_2) \cdots (a_3 b_3) \cdots,$$

where

$$a_1 < a_2 < a_3 \text{ and } b_3 < b_2 < b_1.$$

Let $a_3 = b_3$ denote the special case when a_3 is a fixed point. By setting $(ij) = (a_2 b_2)$, letting $(k\ell)$ be the cycle to the left of (ij) and repeating the arguments from the first case we get an occurrence of (213) in the corresponding permutation $\widehat{\pi}$. Indeed, the fact that b_1 is smaller than b_2 and consequently smaller than every j and also clearly larger than i guarantees that ℓij will form a (213)-subword for some ℓ, i and j.

Finally we consider π, when π is of the form

$$\cdots (a_1 b_1) \cdots (a_2 b_2) \cdots (b_3 a_3) \cdots,$$

where

$$a_1 < a_2 < a_3 \text{ and } b_3 < b_2 < b_1.$$

The special case when a_2 is a fixed point is denoted by $a_2 = b_2$. A (213)-subword is obtained by letting $(ij) = (b_3 a_3)$ and once again applying the above arguments.

This proves that $\mathcal{S}_n(123, 132, 213) = \mathcal{I}_n(2\text{–}3\text{–}1)$. □

We are now prepared to conclude the following result.

Proposition 21. *The number of involutions of $[n]$ that avoid $\mathcal{I}_n(3-2-1)$ is the nth central binomial coefficient $\binom{n}{n/2}$.*

Proof. This follows immediately from Lemma 4 and the fact that $|\mathcal{S}_n(123, 132, 213)| = \binom{n}{n/2}$, shown by Kitaev in [5]. □

3.3.1. *Young tableaux and involutions.* Knuth [8] proves that the number of involutions of $[n]$ is the same as the number of Young tableaux that can be formed from $[n]$. In his proof he constructs a Young tableau from an involution by inserting the letters of the involution into an originally empty Young tableau, using an algorithm I. Together with its inverse D, for deleting elements from a tableau, I is called the *RSK algorithm*, after its creators; Robinson, Schenstedt and Knuth.

Given a Young tableau P and an integer x that is not in P, algorithm I creates a new tableau P' that contains x in addition to its original elements. The tableau P' has the same shape as P except for a new entry added to one of the rows. When inserting the element x into P, it is first compared to the elements in the first row of P. If x is larger than all elements in the first row it is placed as the last element in that row and the algorithm terminates, otherwise it is placed in the position of the smallest element larger than x. This element x' is then inserted into the next row in the same way. The procedure is repeated until an element x' is inserted as the last element of a row.

Example 22. We illustrate the insertion algorithm I by an example. Suppose that we want to insert 4 into the Young tableau P, where

$$P = \begin{array}{|c|c|c|c|}\hline 1 & 3 & 6 & 7 \\ \hline 2 & 9 \\ \cline{1-2} 5 \\ \cline{1-1} 8 \\ \cline{1-1}\end{array} \quad .$$

First, the 4 will be placed in the entry occupied by 6, since 6 is the smallest element larger than 4 in the first row.

$$\begin{array}{|c|c|c|c|}\hline 1 & 3 & 4 & 7 \\ \hline 2 & 9 \\ \cline{1-2} 5 \\ \cline{1-1} 8 \\ \cline{1-1}\end{array}$$

Element 6 is then moved down to the second row where it displaces 9.

$$\begin{array}{|c|c|c|c|}\hline 1 & 3 & 4 & 7 \\ \hline 2 & 6 \\ \cline{1-2} 5 \\ \cline{1-1} 8 \\ \cline{1-1}\end{array}$$

Finally 9 will be placed as the last element in the third row, since the row contains no element larger than 9, and the procedure terminates. The tableau P has now been transformed into P', where

$$P' = \begin{array}{|c|c|c|c|}\hline 1 & 3 & 4 & 7 \\ \hline 2 & 6 \\ \cline{1-2} 5 & 9 \\ \cline{1-2} 8 \\ \cline{1-1}\end{array} \quad .$$

Note that P' has the same shape as P except for the new square, containing 9.

With P' and the position of the entry added when inserting x, it is possible to get back to P by running algorithm I backwards. More generally, given a Young tableau Q and indices (s,t) such that $y = Q_{st}$ is the rightmost element in row s and that column t has no entries below y, algorithm D transforms Q into a Young tableau Q' with no element in position (s,t) but otherwise of the same shape as Q. An element x is then deleted from Q. The method starts by removing the element y from row s and inserting it into row $s-1$ where it displaces the largest element smaller than y. This element y' is in turn moved up to row $s-2$. This procedure continues until an element is removed from the first row. If we apply algorithm D to the tableau P' and the indices of the entry that makes the difference in shape between P' and P, we end up with the original tableau P and the element x. Likewise, if we start with a Young tableau Q and indices (s,t) and apply algorithm D we get a tableau Q' and an element z. Inserting z into Q' according to I will get us back to Q. In this sense the algorithms I and D are inverses of each other.

Example 23. We want to transform the Young tableau P' from example 22 back to its original form P. The entry that makes the difference between the shape of P' and that of P has the indices $(3,2)$, so we start by removing the element in this position, that is 9. The element 9 is inserted into the second row in the position of 6, since 6 is the largest element smaller than 9. Finally 6 replaces element 4 in the first row and we get back to P, with 4 as the deleted element.

$$P' = \begin{array}{|c|c|c|c|}\hline 1&3&4&7\\\hline 2&6\\\cline{1-2}5&9\\\cline{1-2}8\\\cline{1-1}\end{array} \rightarrow \begin{array}{|c|c|c|c|}\hline 1&3&4&7\\\hline 2&9\\\cline{1-2}5\\\cline{1-1}8\\\cline{1-1}\end{array} \rightarrow \begin{array}{|c|c|c|c|}\hline 1&3&6&7\\\hline 2&9\\\cline{1-2}5\\\cline{1-1}8\\\cline{1-1}\end{array} = P \,.$$

By considering a permutation written in two line notation, Knuth constructs a mapping from $\mathcal{S}_n$ to the set of ordered pairs of Young tableaux (P,Q) formed from the elements $\{1,2,\ldots,n\}$, where P and Q have the same shape. This is done by inserting the elements one by one into an initially empty Young tableau, partly by using algorithm I. This mapping is shown to be invertible, so there is a one-to-one correspondence between $\mathcal{S}_n$ and the set of ordered pairs (P,Q), where P and Q are as above.

Next, Knuth shows that if the permutation

$$\pi = \begin{pmatrix} 1 & 2 & \ldots & n \\ a_1 & a_2 & \ldots & a_n \end{pmatrix}$$

corresponds to the ordered pair of tableaux (P, Q), then the inverse permutation

$$\pi^{-1} = \begin{pmatrix} a_1 & a_2 & \dots & a_n \\ 1 & 2 & \dots & n \end{pmatrix}$$

corresponds to (Q, P). Hence, since the involutions are the permutations that are their own inverses they correspond to pairs of tableaux (P, P), and therefore the number of tableaux that can be formed from $[n]$ equals the number of involutions of length n. For a detailed proof we refer to [8].

A consequence of the tableau-constructing method based on algorithm I is that the number of rows in the resulting Young tableau P corresponds to the length of the longest decreasing sequence of the permutation. Indeed, for the algorithm not to terminate before the kth row, the element inserted into row i, where $i \leq k$, has to be smaller than the largest element of the row. That is, an element x that causes a movement down to the kth row must have been preceded by a smaller element in the involution (now in the first row), that in turn must have been preceded by an even smaller element (in the second row) et cetera, that is the involution must contain a decreasing sequence of length k. On the other hand, if we let $a_{i_k} \dots a_{i_1}$ denote the lexicographically smallest decreasing sequence of length k, it is easy to realize that when a_{i_1} has been inserted into the first row, element a_{i_j} will be in row j for each j. Hence the Young tableau will have k rows exactly when the longest decreasing sequence is of length k. In particular $\mathcal{I}_n(3\text{-}2\text{-}1)$ will be in one-to-one correspondence with the Young tableaux with at most two rows. It is known that the number of Young tableaux with two or less rows is the nth central binomial coefficient. For a proof see for example Lundin [9]. This therefore gives another proof of Proposition 21.

As the length of the longest decreasing sequence of the involution determines the number of rows, the length of the longest increasing sequence equals the number of columns. This can be seen from the construction by arguments similar to those above. The set of (1-2-3)-avoiding involutions will therefore be in one-to-one correspondence with the Young tableaux with two or less columns. Taking the transpose of a Young tableau; $P_{ij} \mapsto P_{ji}$, that is reflecting in the NW-SE diagonal, clearly gives a bijection from the tableaux with k rows to the tableaux with k columns. Thus the number of Young tableaux with at most two columns is indeed the nth central binomial coefficient. This proves the following proposition.

Proposition 24. *The number of involutions avoiding (*1-2-3*) is the nth central binomial coefficient* $\binom{n}{n/2}$.

4. Involutions avoiding generalised 3-patterns

So far our work has concerned avoidance of classical patterns. In this section we extend the study to include all generalised 3-patterns.

We start our investigation by counting the pattern-avoiding involutions of $[n]$, when n is small ($n \leq 10$). The results are presented in Table 2.

p	$\lvert\mathcal{I}_n(p)\rvert$	p	$\lvert\mathcal{I}_n(p)\rvert$	p	$\lvert\mathcal{I}_n(p)\rvert$	p	$\lvert\mathcal{I}_n(p)\rvert$
(1-2-3)	$\binom{n}{n/2}$	(1-23)	A_n	(12-3)	A_n	(123)	B_n
(1-3-2)	$\binom{n}{n/2}$	(1-32)	A_n	(13-2)	$\binom{n}{n/2}$	(132)	C_n
(2-1-3)	$\binom{n}{n/2}$	(2-13)	$\binom{n}{n/2}$	(21-3)	A_n	(213)	C_n
(2-3-1)	2^{n-1}	(2-31)	2^{n-1}	(23-1)	2^{n-1}	(231)	D_n
(3-1-2)	2^{n-1}	(3-12)	2^{n-1}	(31-2)	2^{n-1}	(312)	D_n
(3-2-1)	$\binom{n}{n/2}$	(3-21)	E_n	(32-1)	E_n	(321)	B_n.

TABLE 2. Generalised patterns

Here:

$$\begin{aligned} A_n &= 1, 2, 3, 6, 11, 23, 46, 100, 213, 481, \ldots \\ B_n &= 1, 2, 3, 7, 15, 38, 97, 271, 778, 2371, \ldots \\ C_n &= 1, 2, 3, 6, 12, 28, 66, 172, 458, 1305, \ldots \\ D_n &= 1, 2, 4, 8, 17, 39, 94, 241, 646, 1821, \ldots \\ E_n &= 1, 2, 3, 6, 11, 23, 47, 103, 225, 513, \ldots \end{aligned}$$

Further we consult the On-Line Encyclopedia of Integer Sequences [11] for information about the obtained sequences of $|\mathcal{I}_n(p)|$. However, except for the well-known $\binom{n}{n/2}$ and 2^{n-1}, none of them can be found in [11]. Still the enumeration of $A_n, \ldots, E_n$ is of some interest for comparison reasons. For each row in the table there is a hierarchy amongst the patterns. Namely, an occurrence of a one-dash pattern, $(x\text{-}yz)$ or $(xy\text{-}z)$, is a special case of an occurrence of the classical two-dash pattern $(x\text{-}y\text{-}z)$, and an occurrence of the zero-dash pattern (xyz) implies an occurrence of the one-dash patterns. This hierarchy induces a partial ordering of $\mathcal{I}_n(p)$ with respect to inclusion. Accordingly

$$\begin{aligned} \mathcal{I}_n(x\text{-}y\text{-}z) &\subseteq \mathcal{I}_n(x\text{-}yz) \subseteq \mathcal{I}_n(xyz), \\ \mathcal{I}_n(x\text{-}y\text{-}z) &\subseteq \mathcal{I}_n(xy\text{-}z) \subseteq \mathcal{I}_n(xyz), \end{aligned}$$

which implies that

$$\begin{aligned} |\mathcal{I}_n(x\text{-}y\text{-}z)| &\leq |\mathcal{I}_n(x\text{-}yz)| \leq |\mathcal{I}_n(xyz)|, \\ |\mathcal{I}_n(x\text{-}y\text{-}z)| &\leq |\mathcal{I}_n(xy\text{-}z)| \leq |\mathcal{I}_n(xyz)|. \end{aligned}$$

Taking a look at the fourth row of Table 2 above, a consequence of $|\mathcal{I}_n(2\text{-}3\text{-}1)| = |\mathcal{I}_n(2\text{-}31)| = |\mathcal{I}_n(23\text{-}1)|$ is seen to be that $\mathcal{I}_n(2\text{-}3\text{-}1) =$

$\mathcal{I}_n(2\text{-}31) = \mathcal{I}_n(23\text{-}1)$, that is an involution avoids (2-3-1) if and only if it avoids (2-31), which is in turn avoided if and only if (23-1) is avoided. However, for $n \geq 5$, the sequence D_n indicates the existence of involutions that avoid (231) even though they may contain (2-3-1)-subwords. This is in fact the case for $\pi = 52431$.

Proposition 25. *The number of involutions that avoid p, when p is equal to (2-13) or (13-2), is $\binom{n}{n/2}$. Hence*

$$|\mathcal{I}_n(2\text{-}13)| = |\mathcal{I}_n(13\text{-}2)| = \binom{n}{n/2}.$$

For the proof we use a consequence of the proof of Proposition 20.

Porism 26. *[of Proposition 20] For a generalised pattern p we have that $|\mathcal{I}_n(p)| = |\mathcal{I}_n(C \circ R(p))|$.*

Proof. Without loss of generality, the pattern $p = (2\text{-}1\text{-}3)$ in the proof of Proposition 20 could be replaced by any generalised pattern. □

Proof of Proposition 25. In Claesson [1] it is shown that a permutation π avoids (2-13) if and only if it avoids (2-1-3). In particular this is true when π is an involution. Thus, recalling from Proposition 6 that the (2-1-3)-avoiding involutions are counted by $\binom{n}{n/2}$, we obtain the desired result in the first case. An application of Porism 26 to $p = (13\text{-}2) = C \circ R(2\text{-}13)$ then proves the remaining part. □

Proposition 27. *An involution avoids p, where p is one of the patterns (2-31), (31-2), (23-1) or (3-12), if and only if it avoids (2-3-1). Hence*

$$|\mathcal{I}_n(2\text{-}31)| = |\mathcal{I}_n(31\text{-}2)| = |\mathcal{I}_n(23\text{-}1)| = |\mathcal{I}_n(3\text{-}12)| = 2^{n-1}.$$

Proof. Claesson[1] partitions the twelve one dash patterns into three equidistributed classes, with respect to the patterns considered as permutation statistics. This is done on the basis of their behaviour under actions of the trivial bijections.

As mentioned in the proof of Proposition 25, Claesson [1] shows that a permutation avoids (2-13) if and only if it avoids (2-1-3). Due to the properties of the trivial bijections, the corresponding results are true for all patterns in the (2-13) class, that is (2-31), (13-2) and (31-2). In particular, an involution avoids (2-31) if and only if it avoids (2-3-1) and avoidance of (31-2) is equivalent to avoidance of (3-1-2), which in turn, by Lemma 1, is equal to (2-3-1)-avoidance.

Concerning the two remaining patterns we give a proof by describing the pattern-avoiding involutions. Let $\pi = a_1 a_2 \cdots a_n$ be a (23-1)-avoiding involution with k as the first letter. The initial segment $\sigma = a_1 a_2 \cdots a_k$ of π is easily seen to be determined by k. Indeed, the letter 1 must clearly be in position k and since no ascents are allowed to precede 1, the only possibility is to let σ consist of the k smallest letters in decreasing

order. In the same way, the $(k+1)$st letter fixes the subsequent segment, and so forth. This procedure results in an involution of the form that was used to describe $\mathcal{I}_n(2\text{-}3\text{-}1)$ in the proof of Proposition 6. Hence $\mathcal{I}_n(23\text{-}1) \subseteq \mathcal{I}_n(2\text{-}3\text{-}1)$ and since the converse inclusion obviously holds we conclude that $\mathcal{I}_n(23\text{-}1) = \mathcal{I}_n(2\text{-}3\text{-}1)$.

By similar arguments the description of $\mathcal{I}_n(2\text{-}3\text{-}1)$ is easily seen to fit also a $(3\text{-}21)$-avoiding involution, so $\mathcal{I}_n(23\text{-}1) = \mathcal{I}_n(2\text{-}3\text{-}1)$. The details are left to the reader.

We recall from Proposition 6 that the $(2\text{-}3\text{-}1)$-avoiding involutions are counted by 2^{n-1}. Thus the second part of the proposition follows accordingly. □

5. Multiavoidance of 3-patterns among involutions

We devote this final section to the case of multiavoidance, that is when two or more patterns are simultaneously avoided. This was first systematically studied for classical 3-patterns by Simion and Schmidt [10] but has recently been extended to generalised patterns, for instance by Claesson [1], Kitaev [5], [6] and Claesson and Mansour [2].

Consider $\mathcal{I}_n(p_1, \dots p_k)$, where p_i are 3-patterns. Allowing the patterns p_i to be generalised and the number of them, k, to vary, provides us with a huge amount of different restrictions to investigate, even though many of them are not of much interest. Here we limit ourselves to the case of two classical 3-patterns, denoted p and q.

As in the study of generalised patterns we start by counting the involutions of $[n]$ that avoid the pair of patterns p and q, when n is small. The result is presented in Table 3, where a certain cell represents the number of involutions that avoid simultaneously the row and the column pattern.

$p\backslash q$	(1-2-3)	(1-3-2)	(2-1-3)	(2-3-1)	(3-1-2)	(3-2-1)
(1-2-3)		A_n	A_n	n	n	B_n
(1-3-2)			A_n	n	n	C_n
(2-1-3)				n	n	C_n
(2-3-1)					2^{n-1}	D_{n+1}
(3-1-2)						D_{n+1}
(3-2-1)						

Table 3. Double avoidance of classical patterns

Here:

$$\begin{aligned} A_n &= 1, 2, 2, 4, 4, 8, 8, 16, 16, \dots \\ B_n &= 1, 2, 2, 2, 0, 0, 0, 0, 0, \dots \\ C_n &= 1, 2, 2, 3, 3, 4, 4, \dots \\ D_n &= 1, 1, 2, 3, 5, 8, 13, 21, \dots \end{aligned}$$

Note the simplicity of the sequences above, compared to those treated earlier in this work. Also note that the sequence D_n is the well known *Fibonacci numbers*.

First we consider the "simplest" sequence $B_n = 1, 2, 2, 2, 0, 0, 0, \dots$, which counts the involutions that avoid (1-2-3) and (3-2-1). By studying the involutions of length at most 4 it is easy to verify the first 4 B_n's. To realize that an involution of length larger than 4 must have a decreasing or an increasing subsequence of length 3, we recall from the theory behind the proofs of Proposition 21 and 24, that the RSK algorithm gives a bijection between the Young tableaux with n elements and the set of involutions of $[n]$, where the number of rows and columns of the Young tableau equal the length of the longest increasing and decreasing subsequence, respectively. It is easy to see that a Young tableau with $r \cdot c + 1$ elements must have a row containing $r+1$ elements or a column with $c+1$ elements and we conclude that all Young tableaux with $5 = 2 \cdot 2 + 1$ or more elements must have a row or a column with at least 3 elements.

An apparently different approach is to use one of the famous results in combinatorics, proved by Erdős and Szekeres in 1935.

Theorem. *(Erdős-Szekerez) Let $A = (a_1, \dots, a_n)$ be a sequence of n different real numbers. If $n \geq sr + 1$ then either A has an increasing subsequence of $s + 1$ terms or a decreasing subsequence of $r + 1$ terms (or both).*

For a proof, see for example [4]. From the theorem it follows immediately that an involution of $[n]$, where $n \geq 5$, must have a decreasing or increasing sequence of length 3. However, to conclude this we use the same argument as above, namely that $5 = 2 \cdot 2 + 1$. In fact, what we implicitly do above is to prove the Erdős-Szekeres Theorem in the case of integer a_i, via the RSK-algorithm.

Let us continue with the case when one of the avoided patterns is (2-3-1) or (3-1-2). As pointed out in Lemma 1, we have that $\mathcal{I}_n(2\text{-}3\text{-}1) = \mathcal{I}_n(3\text{-}1\text{-}2)$, hence $\mathcal{I}_n(p, 2\text{-}3\text{-}1) = \mathcal{I}_n(p, 3\text{-}1\text{-}2)$, and consequently it suffices to consider either of those sets. Also we conclude the obvious result that $|\mathcal{I}_n(2\text{-}3\text{-}1, 3\text{-}1\text{-}2)| = |\mathcal{I}_n(2\text{-}3\text{-}1)| = |\mathcal{I}_n(3\text{-}1\text{-}2)| = 2^{n-1}$.

Proposition 28. *We have that*

$$\begin{aligned}|\mathcal{I}_n(1\text{-}2\text{-}3, 2\text{-}3\text{-}1)| &= |\mathcal{I}_n(1\text{-}2\text{-}3, 3\text{-}1\text{-}2)| = \\ |\mathcal{I}_n(1\text{-}3\text{-}2, 2\text{-}3\text{-}1)| &= |\mathcal{I}_n(1\text{-}3\text{-}2, 3\text{-}1\text{-}2)| = \\ |\mathcal{I}_n(2\text{-}1\text{-}3, 2\text{-}3\text{-}1)| &= |\mathcal{I}_n(2\text{-}1\text{-}3, 3\text{-}1\text{-}2)| = n.\end{aligned}$$

Proof. We recall the description of $\mathcal{I}_n(2\text{-}3\text{-}1) = \mathcal{I}_n(1\text{-}3\text{-}2)$ from the proof of Proposition 6;

$$\mathcal{I}_n(2\text{-}3\text{-}1) = \{k_1 \cdots 1 k_2 \cdots (k_1+1) k_3 \cdots (k_{\ell-1}+1) n \cdots (k_\ell+1)\}.$$

That is the involutions can be considered as consisting of segments, such that

(a) all letters in segment i are smaller than all letters in segment $(i+1)$,
(b) the elements in a segment are in decreasing order.

Let $\pi = a_1 a_2 \cdots a_n$ be such an involution. We want to investigate what happens when we add the restriction to avoid p, where p is one of the patterns in $\{(1\text{-}2\text{-}3), (1\text{-}3\text{-}2), (2\text{-}1\text{-}3)\}$.

The avoidance of (1-2-3) limits the number of segments of π to two. Indeed, because of property (a) above, if π has more than two segments, a (1-2-3)-subword will be formed as $a_{i_1} a_{i_2} a_{i_3}$, where a_{i_1}, a_{i_2} and a_{i_3} can be arbitrarily chosen from the first, second and third segment respectively. Thus it follows that π in $\mathcal{I}_n(1\text{-}2\text{-}3, 2\text{-}3\text{-}1)$ is of the form

$$\pi = k \cdots 1 n \cdots (k+1),$$

that is, the involution π is uniquely determined by the choice of k, hence

$$|\mathcal{I}_n(1\text{-}2\text{-}3, 2\text{-}3\text{-}1)| = |\mathcal{I}_n(1\text{-}2\text{-}3, 3\text{-}1\text{-}2)| = n.$$

When the patterns (1-3-2) and (2-3-1) are to be simultaneously avoided, π can not have any "peaks". No letter a_i can be both preceded and succeeded by smaller letters. Consequently, if the letter 1 is in position k, then π must consist of the k smallest letters in decreasing order, followed by the letters that are larger than k in increasing order. To use the above notation, all segments except for the first one contain only one letter. Accordingly $\mathcal{I}_n(1\text{-}3\text{-}2, 2\text{-}3\text{-}1)$ consists of all permutations π of the form $\pi = k(k-1)\cdots 1(k+1)\cdots n$. Again the choice of k fixes the remaining involution, so it follows that

$$|\mathcal{I}_n(1\text{-}3\text{-}2, 2\text{-}3\text{-}1)| = |\mathcal{I}_n(1\text{-}3\text{-}2, 3\text{-}1\text{-}2)| = n.$$

Likewise, avoiding the patterns (2-1-3) and (3-1-2) implies that there can not be any "valleys", so, if the letter n is in position $(k+1)$, it must be preceded by the k smallest letters in increasing order and followed by the larger letters in decreasing order. This time each segment but the first one consists of a single letter, thus an involution π in $\mathcal{I}_n(2\text{-}1\text{-}3, 3\text{-}1\text{-}2)$

can be written $\pi = 12\cdots kn(n-1)\cdots(k+1)$, from which we conclude that

$$|\mathcal{I}_n(2\text{-}1\text{-}3, 2\text{-}3\text{-}1)| = |\mathcal{I}_n(2\text{-}1\text{-}3, 3\text{-}1\text{-}2)| = n,$$

since each involution is fully determined by k. □

Proposition 29. *We have that*

$$|\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)| = |\mathcal{I}_n(3\text{-}2\text{-}1, 3\text{-}1\text{-}2)| = F_{n+1},$$

where F_n denotes the nth Fibonacci number.

Note that, as in the proof of Proposition 28, it suffices to study either $\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$ or $\mathcal{I}_n(3\text{-}2\text{-}1, 3\text{-}1\text{-}2)$ since the two sets are indeed the same.

Consider π in $\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$. Being a $(2\text{-}3\text{-}1)$-avoiding involution, π can be described as consisting of segments, within which the letters are decreasingly ordered, according to the above characterization of $\mathcal{I}_n(2\text{-}3\text{-}1)$. Furthermore, the avoidance of $(3\text{-}2\text{-}1)$ implies that the decreasing sequences must be of length at most two, so π consists of fixed points and 2-cycles of consecutive letters. Hence

$$\pi = \cdots(k_i)\cdots(k_j, k_j+1)\cdots$$

gives a description of π in cycle form.

We prove that the involutions of the above form are counted by the Fibonacci numbers, first by combining two of the proofs of Proposition 6 with well known properties of the Fibonacci numbers and then by recursively constructing $\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$ from $\mathcal{I}_{n-1}(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$ and $\mathcal{I}_{n-2}(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$.

First proof. We begin with a proof that refers to the first proof of Proposition 6, in which a bijection Φ_n from the binary strings of length $(n-1)$, to $\mathcal{I}_n(2\text{-}3\text{-}1)$ is constructed. Given a binary string $x = x_1\cdots x_{n-1}$ in B_{n-1}, the corresponding involution is recursively built up from $[n]$ by considering the letters x_i, one at at time. We recall that $x_i = 1$ causes an inversion to be formed as the letter i is placed before $(i-1)$, whereas $x_i = 0$ implies that i is placed as the last element so far. From the construction it is easily seen that π contains a decreasing subsequence of length larger than 3 whenever x has two consecutive 1's and conversely that an x with no two consecutive 1's maps to an involution of the form

$$\cdots(k_i)\cdots(k_j, k_j+1)\cdots.$$

Hence there is a one-to-one correspondence between $\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$ and the binary strings of length $n-1$ with no consecutive 1's, which are known to be counted by F_{n+1}. For a reference, see for example [11]. Thus it follows that

$$|\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)| = |\mathcal{I}_n(3\text{-}2\text{-}1, 3\text{-}1\text{-}2)| = F_{n+1}.$$

□

Second proof. Next we relate to the third proof of Proposition 6, in which a bijection between $\mathcal{P}_{n-1}$, the subsets of $[n-1]$, and $\mathcal{I}_n(2\text{-}3\text{-}1)$ is defined. Let A be in $\mathcal{P}_{n-1}$. The corresponding involution is constructed from A by letting i be preceded by a larger letter if and only if i belongs to A. From the appearance of $\mathcal{I}_n(2\text{-}3\text{-}1)$ we see that there is only one choice of the larger letter preceding i, namely $i+1$. Thus, π has an occurrence of $(3\text{-}2\text{-}1)$ if and only if A contains two or more consecutive integers. It is well known that the number of subsets of $[n]$ with no consecutive integers is the nth Fibonacci number, see for instance [11]. Thus the result follows. □

Third proof. Finally we give a proof by induction. Recall that the Fibonacci numbers are defined by

$$F_n = F_{n-1} + F_{n-2}, \text{ where } F_0 = 0, F_1 = 1.$$

We will now show that the number of $(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$-avoiding involutions of $[n]$ satisfies the same recursion. Let π be such an involution. From the above description of $\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)$ as consisting only of fixed points and 2-cycles of consecutive letters we see that the letter n will be either a fixed point or contained in the cycle $(n-1, n)$. This gives us two ways of recursively constructing $\mathcal{I}_n(p, q)$ from $\mathcal{I}_{n-1}(p, q)$ and $\mathcal{I}_{n-2}(p, q)$ (for convenience we let the patterns $(3\text{-}2\text{-}1)$ and $(2\text{-}3\text{-}1)$ be denoted by p and q). Either n is added to a (p, q)-avoiding involution of $[n-1]$ or the cycle $((n-1)n)$ is added to a (p, q)-avoiding involution of $[n-2]$. Hence

$$\begin{aligned}\mathcal{I}_n(p,q) &= \{b_1 \cdots b_{n-1} n,\ b_1 \cdots b_{n-1} \in \mathcal{I}_{n-1}(p,q)\} \cup \\ &\quad \{c_1 \cdots c_{n-2} n(n-1),\ c_1 \cdots c_{n-2} \in \mathcal{I}_{n-2}(p,q)\},\end{aligned}$$

so

$$|\mathcal{I}_n(p,q)| = |\mathcal{I}_{n-1}(p,q)| + |\mathcal{I}_{n-2}(p,q)|.$$

Since $\mathcal{I}_0(p, q) = 0$ and $\mathcal{I}_1(p, q) = 1$, we conclude that

$$|\mathcal{I}_n(3\text{-}2\text{-}1, 2\text{-}3\text{-}1)| = |\mathcal{I}_n(3\text{-}2\text{-}1, 3\text{-}1\text{-}2)| = F_{n+1}.$$

□

Proposition 30. *We have that*

$$|\mathcal{I}_n(1\text{-}3\text{-}2, 3\text{-}2\text{-}1)| = |\mathcal{I}_n(2\text{-}1\text{-}3, 3\text{-}2\text{-}1)| = \lfloor n/2 \rfloor + 1.$$

Proof. Consider $\mathcal{I}_n(2\text{-}1\text{-}3, 3\text{-}2\text{-}1)$. We recall from the proof of Proposition 18 that a permutation π, with 1 in position k, avoids $(2\text{-}1\text{-}3)$ if and only if it can be written as $\sigma 1 \tau$, where $\sigma = a_1 a_2 \cdots a_{k-1}$ is a $(2\text{-}1\text{-}3)$-avoiding permutation of $\{n, (n-1), \ldots, (n-k+2)\}$ and $\tau = a_{k+1} a_{k+2} \cdots a_n$ is a $(2\text{-}1\text{-}3)$-avoiding permutation of $\{2, 3, \ldots, (n-k+1)\}$. Furthermore we recall that, when π is an involution, the letter 1 can be either a fixed point or in position k, where $k \geq n/2$. Let us investigate the latter case. Clearly, the letter k is in position 1. In order to avoid $(3\text{-}2\text{-}1)$, the remaining σ must consist of letters larger than k in increasing order. We

realize that this leads to absurdity whenever $k > n/2$ (since there are not enough larger letters). Thus, k must simultaneously be larger than or equal to $n/2$ and less then or equal to $n/2$, which is possible for integer k only when n is even. Then $k = n/2$, which determines π to be equal to $n/2 \cdots n1 \cdots (n/2-1)$. When 1 is a fixed point we can recursively apply the above reasoning to τ, so that an involution in $\mathcal{I}_n(2\text{–}1\text{–}3, 3\text{–}2\text{–}1)$ can be written as $\pi = 12\cdots(n-2k-1)(n-2k)\rho$. Here ρ is the $(2\text{–}1\text{–}3, 3\text{–}2\text{–}1)$-avoiding involution of $\{(n-2k), (n-2k+1), \ldots, n\}$ in which the smallest letter is in the middle position. Thus, these involutions are fully characterized by the choice of k, where k has to be less than or equal to $n/2$, hence

$$|\mathcal{I}_n(2\text{–}1\text{–}3, 3\text{–}2\text{–}1)| = \lfloor n/2 \rfloor + 1.$$

For the $(1\text{–}3\text{–}2)$- and $(3\text{–}2\text{–}1)$-avoiding involutions the proposition can be proved in a similar way, for which we omit the details. Let $\pi = a_1 a_2 \cdots a_n$ be such an involution. The letter n can either be a fixed point or, if n is even, in position $n/2$, in which case it determines the rest of π. By recursively repeating the arguments to the segment $a_1 a_2 \cdots a_{n-1}$ when n is a fixed point, we see that an $(1\text{–}3\text{–}2, 3\text{–}2\text{–}1)$-avoiding involution π can be written as $\rho(2k)(2k+1)\cdots n$, where ρ is the $(1\text{–}3\text{–}2, 3\text{–}2\text{–}1)$-avoiding involution of $[2k-1]$, in which the largest letter is in the middle position. Again the involutions are uniquely determined by the choice of k, hence the result follows. □

Proposition 31. *We have that*

$$\begin{aligned} |\mathcal{I}_n(1\text{–}2\text{–}3, 1\text{–}3\text{–}2)| &= |\mathcal{I}_n(1\text{–}2\text{–}3, 2\text{–}1\text{–}3)| = \\ |\mathcal{I}_n(1\text{–}3\text{–}2, 2\text{–}1\text{–}3)| &= 2^{\lfloor n/2 \rfloor}. \end{aligned}$$

Proof. We start with the case of $(1\text{–}2\text{–}3)$- and $(2\text{–}1\text{–}3)$-avoiding involutions of $[n]$. Note that the largest letter, n, has to be in position 1 or 2, because otherwise n will be preceded by two smaller letters that are either ordered as $(1\text{–}2)$ or $(2\text{–}1)$, causing occurrences of $(1\text{–}2\text{–}3)$ and $(2\text{–}1\text{–}3)$ respectively. On the other hand if n is the first (or second) letter, there can not be any $(1\text{–}2\text{–}3)$- or $(2\text{–}1\text{–}3)$-subwords containing 1 (or 2) or n, since n can not act as a 1 or a 2, as well as 1 (or 2) in position n will not do as a 3. Therefore, letting $(1\text{–}2\text{–}3)$ and $(2\text{–}1\text{–}3)$ be denoted by p and q, we can recursively construct $\mathcal{I}_n(p,q)$ from $\mathcal{I}_{n-2}(p,q)$, according to

$$\begin{aligned} \mathcal{I}_n(p,q) &= \{n a_2 \cdots a_{n-1} 1,\ \ \mathrm{proj}(a_2 \cdots a_{n-1}) \in \mathcal{I}_{n-2}(p,q)\} \cup \\ &\quad \{a_1 n a_3 \cdots a_{n-1} 2,\ \ \mathrm{proj}(a_1 a_3 \cdots a_{n-1}) \in \mathcal{I}_{n-2}(p,q)\}. \end{aligned}$$

Hence we get the recursion formula

$$|\mathcal{I}_n(p,q)| = 2 \cdot |\mathcal{I}_{n-2}(p,q)|, \text{ where } \mathcal{I}_1(p,q) = 1 \text{ and } \mathcal{I}_2(p,q) = 2,$$

from which it follows that

$$|\mathcal{I}_n(1\text{–}2\text{–}3, 1\text{–}3\text{–}2)| = 2^{\lfloor n/2 \rfloor}.$$

Next we consider (1–2–3)- and (2–1–3)-avoidance. This is similar to the above case, but now with the letter 1 playing the role of n. For an involution π to be in $\mathcal{I}_n(1\text{–}2\text{–}3, 2\text{–}1\text{–}3)$, the 1 can be placed either as the last or the penultimate letter of π. As above, none of the two corresponding cycles $(1, n)$ or $(1, n-1)$ can possibly contribute to the formation of (1–2–3)- or (2–1–3)-subwords. So, letting p and q denote the patterns (1–2–3) and (2–1–3) respectively, we see that $\mathcal{I}_n(p, q)$ can be recursively constructed from $\mathcal{I}_{n-2}(p, q)$ as

$$\begin{aligned} \mathcal{I}_n(p,q) \;=\; & \{n a_2 \cdots a_{n-1} 1,\ \mathrm{proj}(a_2 \cdots a_{n-1}) \in \mathcal{I}_{n-2}(p,q)\} \cup \\ & \{(n-1) a_2 \cdots a_{n-2} 1 a_n,\ \mathrm{proj}(a_2 \cdots a_{n-2} a_n) \in \mathcal{I}_{n-2}(p,q)\}. \end{aligned}$$

This will once again result in the recursion

$$|\mathcal{I}_n(p, q)| = 2 \cdot |\mathcal{I}_{n-2}(p, q)|,$$

with initial conditions $\mathcal{I}_1(p, q) = 1$ and $\mathcal{I}_2(p, q) = 2$. Thus the result follows.

Finally we turn to the (1–3–2)- and (2–1–3)-avoiding involutions of $[n]$. Let π be such an involution. From the proof of Proposition 18 we recall that, in order to avoid (2–1–3), the letter 1 must be in position $k \geq n/2+1$, or it is a fixed point. However, the simultaneous avoidance of (1–3–2) precludes the latter alternative in all cases except the identity permutation $\pi = 12 \cdots n$. Assume therefore that the letter 1 is in position k. According to the proof of Proposition 18, π can be written as $\sigma 1 \tau$ where τ is a (2–1–3)-avoiding permutation of $\{2, \ldots, (n-k+1)\}$. We realize that the only choice of τ that makes π (1–3–2)-avoiding is in fact $\tau = 23 \cdots (n-k+1)$, which corresponds to the initial segment $a_2 \cdots a_k$ of π. We can then write $\pi = k(k+1) \cdots n \rho 12 \cdots (n-k+1)$, where ρ is a (1–3–2)-avoiding involution of $\{n-k+2, n-k+1, \ldots k-1\}$, that is $\mathrm{proj}(\rho) \in \mathcal{I}_{n-2k}(1\text{–}3\text{–}2, 2\text{–}1\text{–}3)$. Accordingly, with p and q denoting (1–3–2) and (2–1–3) respectively, we can construct $\mathcal{I}_n(p, q)$ from $\{\mathcal{I}_{n-2k}(p, q)\}$, where

$k \leq n/2$. We have that

$$\begin{aligned}\mathcal{I}_n(p,q) &= \{na_2\cdots a_{n-1}1,\ \ \mathrm{proj}(a_2\cdots a_{n-1}) \in \mathcal{I}_{n-2}(p,q)\} \cup \\ &\quad \{(n-1)na_3\cdots a_{n-2}12,\ \ \mathrm{proj}(a_3\cdots a_{n-2}) \in \mathcal{I}_{n-4}(p,q)\} \cup \\ &\quad \vdots \\ &\quad \{k(k+1)\cdots na_{n-k+2}\cdots a_{k-1}12\cdots(n-k+1), \\ &\quad\ \mathrm{proj}(a_{n-k+2}\cdots a_{k-1}) \in \mathcal{I}_{n-2(n-k+1)}(p,q)\} \cup \\ &\quad \vdots \\ &\quad 12\cdots n.\end{aligned}$$

Thus $|\mathcal{I}_n(p,q)|$ satisfies the recursion

$$|\mathcal{I}_n(p,q)| = \sum_{k=1}^{\lfloor n/2 \rfloor} |\mathcal{I}_{n-2k}(p,q)|$$

and, since $|\mathcal{I}_1(p,q)| = 1$ and $|\mathcal{I}_2(p,q)| = 2$, we conclude that

$$|\mathcal{I}_n(1\text{–}3\text{–}2, 2\text{–}1\text{–}3)| = 2^{\lfloor n/2 \rfloor}.$$

□

Acknowledgement

I would like to thank my supervisor Einar Steingrímsson for the support and encouragement I have received during the writing of this masters thesis and also for teaching me combinatorics. I would also like to thank Sverker Lundin for showing me how to use Mathematica in my work with pattern avoidance.

A TREE IN A BRAIN TUMOR

TAEIL YI

University of Florida

ABSTRACT. We use a *shelling procedure* to construct a semi-automated sphere packing treatment plan for brain tumors. We develop a new code to denote an unlabeled tree, and we use it to obtain a complete classification of unlabeled n-trees. We also produce a *Mathematica* program to list for each n, all *perfect sequences* corresponding to n-trees, as well as their graphs. We then develop an algorithm and a program to analyze the brain tumor shapes using trees and perfect sequences.

I. An Automated Sphere Packing Plan for Brain Tumors

The goal of stereotactic radiosurgery for a brain tumor is to deliver the desired dosage to the target, and only the target. This is not possible in reality. So they do the next best thing, which is to deliver enough dosage to the target, to avoid as much normal tissue as possible, and to deliver as little radiation as possible to whatever normal tissue must be affected. There are two additional important criteria–dose homogeneity and dose conformality. That is, we do not want 'hot spots,' which have been experimentally determined to cause complications; and we do want rapid falloff of dose levels outside the actual tumor. One of several such radiation surgery methods is called the 'Multiple Isocenter Method.' This involves filling the tumor image with spheres of different sizes, until the image is best filled up. This noninvasive method of surgery, namely by using radiation, relies on a piece of equipment called the *Linear Accelerator* (or simply, *Linac*). Most of the information in this section about treatment of a brain tumor is taken from Friedman et al.[4]. See [4] for further reference.

1. Making a Sphere by Arcs of Beams

According to [4], the linear accelerator is a complex machine capable of producing X-rays. A large amount of energy is generated by the power supply, which then powers the filament shown. This causes electrons to be emitted by the filament, which are in turn accelerated to higher energies using a (micro-)wave guide. The electrons are then changed in direction by the magnet so that they impact on a heavy metal alloy target. This results in X-ray production that can then be collimated or shaped by both primary and secondary collimators within the linear accelerator head. This beam is further collimated for radiosurgery by the tertiary radiosurgery collimator.

The Linac is mounted on a rotating gantry such that the beam has a center of rotation about 1.5m above the floor. Usually, the isocenter accuracy is defined within a 2mm sphere. Because stereotactic radiosurgery depends on optimized

Key words and phrases. brain tumor, sphere packing, linac, cutpoint, unlabeled graph, unlabeled tree, maximal tree, perfect sequence, shelling procesure .

accuracy, an improved system was designed at the University of Florida, by adding a set of bearings to the stereotactic collimator system and under the patient table. As a result, this new system achieves mechanical accuracy within 0.2mm±0.1mm for defining the treatment isocenter of beam delivery.

The tertiary collimators are generally circular and allow improved centering of the treatment beam. The sizes of these collimators are from 5 to 40mm in 2- to 5-mm increments.

By varying the angle of the gantry and the angle of the table, one can deliver a radiation beam to the target from any angle within the range of the rotation. The shape of the common intersection of an arc of beams passing through one isocenter is a sphere. The neurosurgeons deliver a series of arcs (usually 5 or 9 arcs) to produce a single isocentered sphere shape. For an ellipsoidal target, they use fewer numbers of arcs to make a single isocentered ellipsoid shape.

So, if the target shape is very close to a sphere or an ellipsoid, then the treatment plan is relatively easy compared to an irregularly shaped target. In that case, we need to create a geometric treatment plan.

2. Sphere Packing Plan

As seen in the previous subsection, the physicians know how to irradiate-to-destroy tumors which are shaped like spheres or ellipsoids. For a non-spherical shape of tumor, they try to fill the target with several spheres of different sizes. This is called the 'sphere packing' treatment plan.

After finding a sphere packing plan, they treat each sphere separately as described in the previous subsection. So, multiple isocenter radiosurgery planning includes the problem of determining the best sphere packing arrangement with which to fill the target volume. General methods for this treatment plan are iteratively based, dosimetrically driven algorithms. But these methods require many computations in order to compute a radiosurgical plan dose distribution, and then to evaluate the quality of the dose distribution. So geometrically based radiosurgery optimization has been suggested as a possible alternative means.

However the method the physicians choose relies on human decisions and experience. Thus, for the same target, different surgeons may produce different plans. Even the same surgeon, doing the plan twice for the same target, may produce different plans. And the planning takes a long time, especially for a complicated target which needs more than 10 spheres. It might take as much as two hours of planning for a difficult case which needs about 20 spheres. During that time, the patient has to wait with the head ring attached to his or her head. And most importantly, even after spending the time to make a plan, many physicians without sufficient experience, are not sure if the plan is a 'good' one.

Therefore, we provide a semi-automated sphere packing method for the treatment plan (see [19]). This method shows potential to significantly aid the planning of difficult multiple isocenter cases. Based on tests with irregularly shaped phantom targets and with a representative sampling of clinical example cases, the method demonstrates the ability to generate radiosurgery plans comparable to, or of better quality than, multiple isocenter Linac radiosurgery plans found in other literature. At the same time, this program always produces the same treatment plan for the same tumor shape. So it can be used as a 'benchmark' to compare with other plans

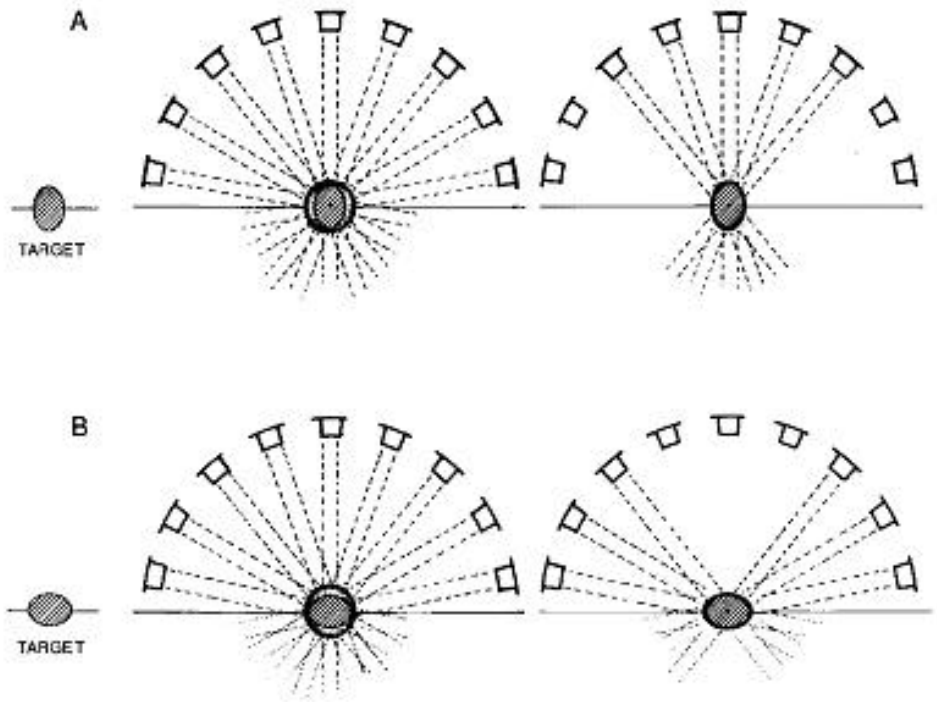

Figure I-1. Plan for a sphere shape and an ellipsoidal shape ([4])

for the given tumor shape. Moreover, this program provides the treatment plan in a relatively short time. For a very difficult case which needed more than 18 spheres, this program took less than 3 minutes instead of more than the 1.5 hours which were needed when the physicians created the plan using traditional methods.

In the following subsection, we explain the 'shelling procedure' which we used in this program to get the centers and sizes of spheres for the sphere packing plan.

3. Shelling Procedure

The shelling procedure is best illustrated in Figure I-2 to I-10. The major steps of this shelling procedure are as follows.

Step 1 Transfer the data of the boundary of the target to the three dimensional array and assign a status value for each voxel. (See Figure I-2 and I-3).

Step 2 Shell the target voxels (See Figure I-4).

We program a prodecure to count the number of layers of the largest sphere(s), and identify the deepest voxel(s). Occasionaly, several voxels remain at the deepest level. When this occurs, the *score function* is requested which is derived by Thomas Wagner. (see [19])

Step 3 Remove the largest sphere (as chosen by the score function, if use)

We think of the largest radius sphere as being removed, and repeat the process inductively. (See Figures I-5 to I-10.)

For further detailed information about the score function and the automated sphere packing plan, we refer the reader to [18] and [19].

II. A Classification of Unlabeled Trees

In this section, we obtain a new code to denote an unlabeled tree. By means of this code, we classify unlabeled n-trees. In particular, we call a tree an *n-tree* if and only if it is a tree with n vertices (that is, $(n-1)$ edges). Our code assigns a unique, ordered, 'perfect sequence', $pf(T) = \langle d_1, d_2, \ldots, d_n \rangle$, to each unlabeled n-tree, T. And, conversely, given an ordered sequence of n integers satisfying certain properties, it is the perfect sequence of exactly one unlabeled n-tree.

Our work includes an algorithm and a *Mathematica* program that produce a list of all the perfect sequences for all possible n-trees, thus also producing the number of n-trees, for any given n. Some examples are given below.

However, we do not have a *simple formula* that tells us how many unlabeled n-trees there are. This remains an open problem.

1. Perfect Sequence for a Tree

Let T be the unlabeled tree below, but we labeled the vertices of T as shown to construct a degree sequence.

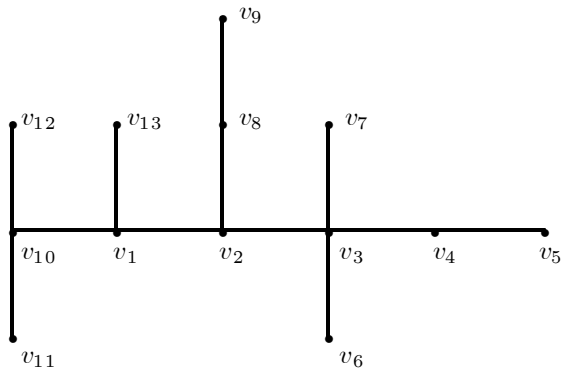

Figure II-5

For the chosen vertex sequence $V = \langle v_1, v_2, ..., v_{13} \rangle$, we can get the degree sequence, $D = \langle 3, 2, 3, 1, 0, 0, 0, 1, 0, 2, 0, 0, 0 \rangle$.

(a) Let $D = \langle 3, 2, 3, 1, 0, 0, 0, 1, 0, 2, 0, 0, 0 \rangle = \langle d_1, d_2, ..., d_{13} \rangle$. Then d_i equals (the degree of v_i) - 1, except the first term in which d_1 = the degree of v_1. Clearly, $\sum_{i=1}^{13} d_i = 12$, which is the number of edges in T.

(b) Every pair of consecutive terms in the sequence are connected in T except for the end vertices. We choose one of the closest vertices to the end vertex, that is not selected yet in the sequence. For example, since the vertex v_5 is an end vertex, we don't have any remaining unselected vertex connected to v_5. Then there are two (closest to v_5,) unselected vertices, v_6 and v_7. We could choose either of them for the next term after v_5.

We showed that, for a given tree T, there exist many vertex sequences, therefore degree sequences, depending on the starting vertex and choice among the adjacent vertices for each successive vertex. Therefore the degree sequence set $\mathcal{D}$ for the given tree T contains many different degree sequences which denote the same tree T. We need a way to choose one degree sequence representing the tree T. So we define an order on the set of all finite, nonnegative, integer sequences, and then we define a *perfect sequence* to be the unique maximum element under this order.

Theorem 1 [Tree Classification Theorem] *For any positive integer n, let $\mathcal{T}(n)$ be the set of unlabeled n-trees and $\mathcal{P}(n)$ the set of perfect sequences of length n. Then there is a one-to-one correspondence between $\mathcal{T}(n)$ and $\mathcal{P}(n)$.*

2. Some Program Results

Our notation for a degree sequence is $\langle d_1, d_2, \ldots, d_n \rangle$. But the *Mathematica* program produces the sequence notation with { and }. So in this subsection, any set notation actually denotes the degree sequence. Note that an n-tree has n vertices, so there are n-1 edges.

```
     n=3          total number of degree sequences : 1

```

III. A Tree for a Brain Tumor

In section I, an automated sphere packing treatment plan for a given brain tumor is developed.

From that plan, we can assign a unique corresponding graph by matching a sphere with a vertex and matching the adjacency of two spheres with an edge. Then, by using the notion of *cutvertex* (a separating vertex), we give an order to the vertex set. We use this order to decide which edges to choose in order to obtain a *unique maximal tree* contained in the graph. We assume that a brain tumor is connected, so the graph representation for any brain tumor is a connected graph.

1. Cutvertex and Block

Let G be a graph with 14 vertices and 18 edges as in the Figure III-1 below.

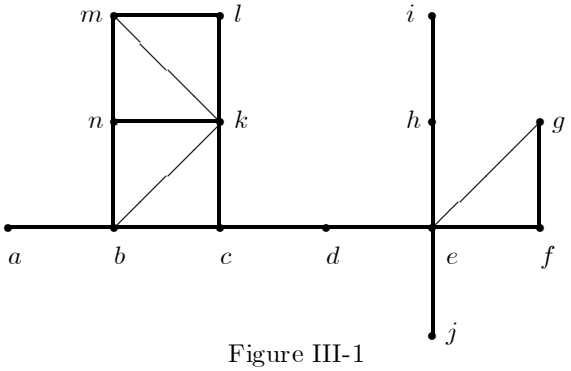

Figure III-1

There are 3 cutvertices, b, c, e. So the given graph G can be separated into 6 blocks as follows:

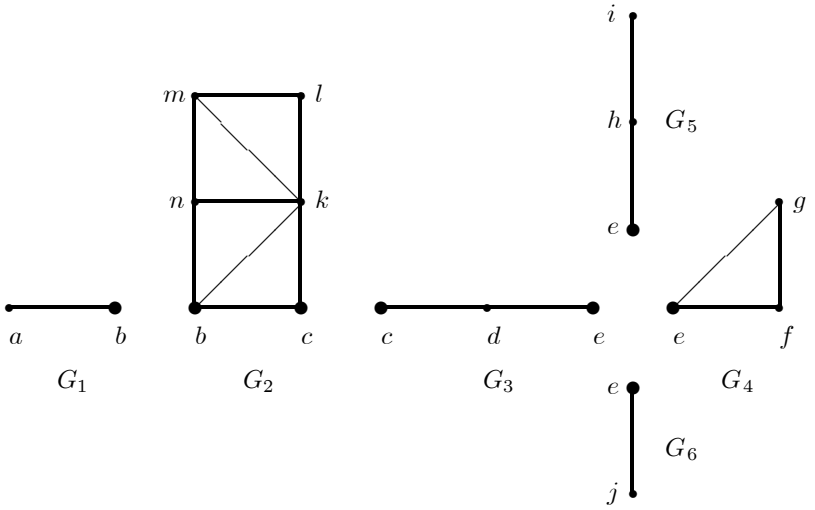

Figure III-2

2. Order in the Vertex Set

To get a maximal tree from a graph we may need to delete some edges in the graph. Thus we need to label each vertex in order to choose certain edges to delete, even though we are dealing with an unlabeled graph in this article. So there is no specific meaning for this labeling except that it is only used to choose a maximal tree for the graph.

Example III-1. Let P be the sphere packing treatment plan (see Figure III-3) for a given brain tumor, shown below.

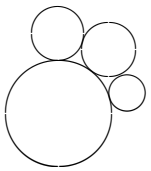

Figure III-3

Then there is a unique graph G for the sphere packing plan. The graph is given below in Figure III-4.

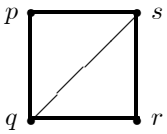

Figure III-4

There are two different isomorphism classes, namely T_1 and T_2, of maximal trees for the graph G. That is, we could choose either of these for a maximal tree to assign the graph G. Since, in our algorithm, we want to get the same maximal

tree for a given graph every time, we need certain rules to get the same tree. (See Figure III-5.)

Figure III-5

In this section, we assume that the graph comes from a sphere packing treatment plan. That is, the main shape of the brain tumor depends on the size of spheres and the connection between spheres. Even though we cannot keep the information about the size of spheres in the graph, it seems to us that the bigger the sphere is, the more it has a chance to get attached to more spheres. And we assume that the larger degree vertices play a more important role in classifying the tumor shapes into trees than the smaller degree vertices. That is, by choosing a largest degree vertex first, the shape of the tumor is apparently most closely preserved. Thus, in the previous example, we choose the vertex q or s as the starting vertex; then we pick all the incident edges (see Figure III-4). Then we get the tree T_1. Therefore we want to choose the tree T_1 for the maximal tree of G. Note that the tree T_2 produces a linear graph which does not show the shape of the tumor as closely as T_1.

But there are some vertices which are more important than the larger degree vertices. Recall the graph G in the subsection III-1. Then, in the block G_2, it is clear that the vertex k has the largest degree, 5. But the cutvertices, b and c, play a critical role in obtaining a maximal tree of G. So, to get a maximal tree for a graph G, we want to start at the cutvertices of G first, instead of the vertices with the largest degree. So we want to label the cutvertices first. On the other hand, there are different kinds of 'cutvertices' in some graphs. The following example shows such a case.

Example III-2 Let $G = \{V, E\}$ be the graph in Figure III-6.

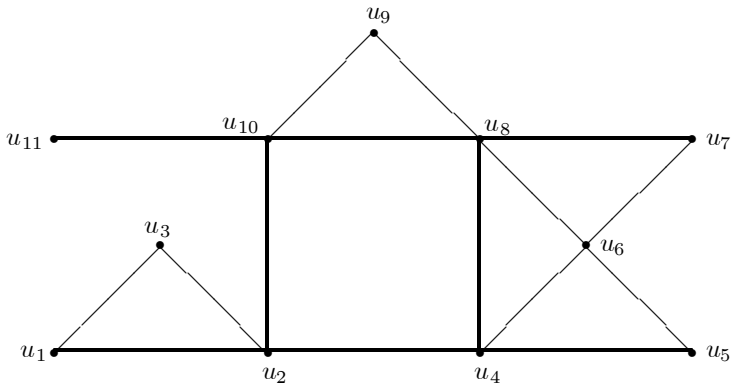

Figure III-6

Then there are two cutvertices of the graph G, namely u_2 and u_{10}. Using these two cutvertices, the graph G is separated into four subgraphs, namely G_1, G_2, G_3 and G_4. (See Figure III-7.)

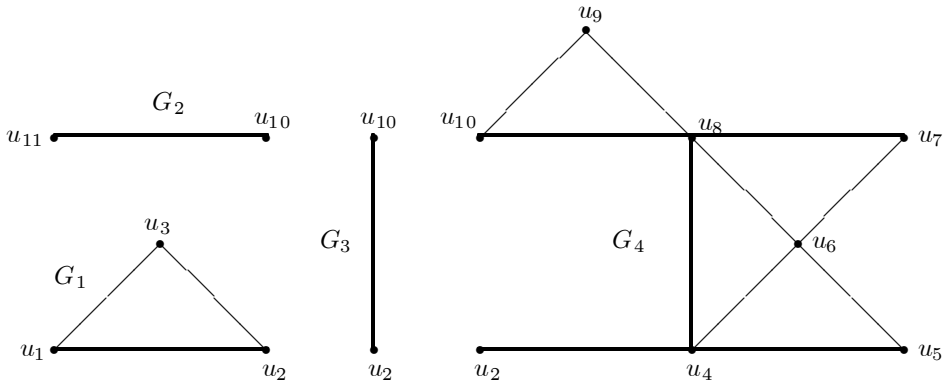

Figure III-7

Then the subgraphs G_1, G_2, and G_3 are blocks, but the subgraph G_4 contains its own cutvertices, u_4 and u_8, which are not cutvertices of the graph G. We separate the subgraph G_4 into four subgraphs by using its cutvertices u_4 and u_8. (See Figure III-8.) Note that there is no specific order in labeling the subgraphs. So at this moment, we relabel the subgraphs of G by H_1, H_2, ..., H_7.

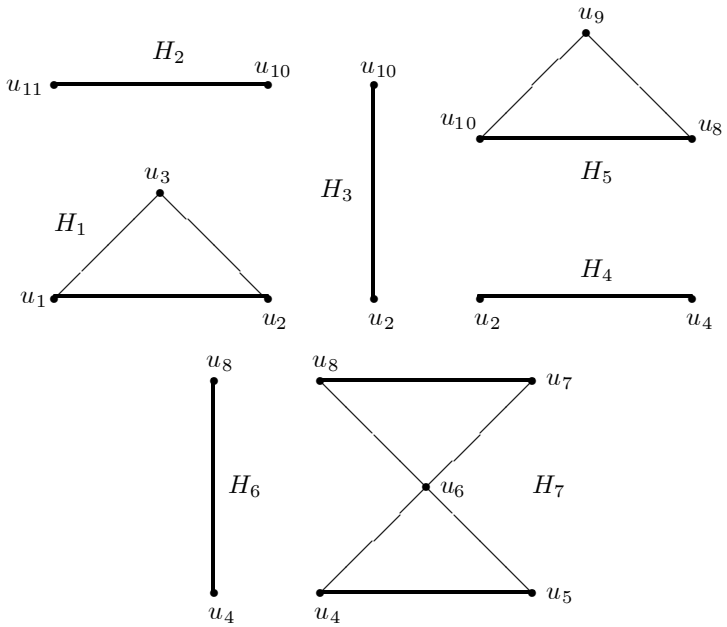

Figure III-8

Then, again, the subgraphs H_1, H_2, ..., H_6 are blocks, but the subgraph H_7 contains its own cutvertex, u_6, which is neither a cutvertex of the graph G

nor a cutvertex of the subgraph G_4. We separate this subgraph H_7 into two subgraphs by using u_6. (See Figure III-9.) And we relabel the subgraphs of G by $B_1,\ B_2,\ \ldots\ ,\ B_8$.

Therefore $\{u_2, u_{10}\}$ is the set of cutvertices of the graph G. But $\{u_4, u_8\}$ is the set of the cutvertices of a subgraph which is produced after the first separation using the cutvertices of the graph, and u_6 is the cutvertex of a subgraph which is produced after the second separation.

For the purpose of labeling the vertices in a graph, we separate these cutvertex sets for different levels, from each other.

Let G be the graph assigned for a given sphere packing plan P. Then the vertex set $V(G)$ of the graph G is the union of two disjoint subsets, namely $C_1(G)$ and $C_1^c(G)$, where $C_1(G) = \{v \in V(G) |\ v$ is a cutvertex of $G\}$ and $C_1^c(G) = V(G) - C_1(G)$. We call $C_1(G)$ the *first step cutvertex set* of G. For every $i = 2,3,\ldots,|V(G)|$, we define a subset $C_i(G)$ of $C_{i-1}^c(G)$ as the collection of the vertices of $C_{i-1}^c(G)$, which are cutvertices of a subgraph produced after the $(i-1)$-th separation using the elements of $C_{i-1}(G)$. Then we call $C_i(G)$ the *i-th step cutvertex set* of G, and let $C_i^c(G) = C_{i-1}^c(G) - C_i(G)$. We assume that there are finitely many vertices in a given graph. If there exists at least one cutvertex, then there exists an integer $1 \le k \le n$ such that $C_i(G) \neq \emptyset$ for every $i \le k$, and $C_i(G) = \emptyset$ for every $i \ge k+1$. Then we call k the *separation step constant* of the graph G, and let $C^c(G) = (C_k)^c(G)$.

If there is no cutvertex of G then the graph is a block, and we say that the separation step constant of G is 0.

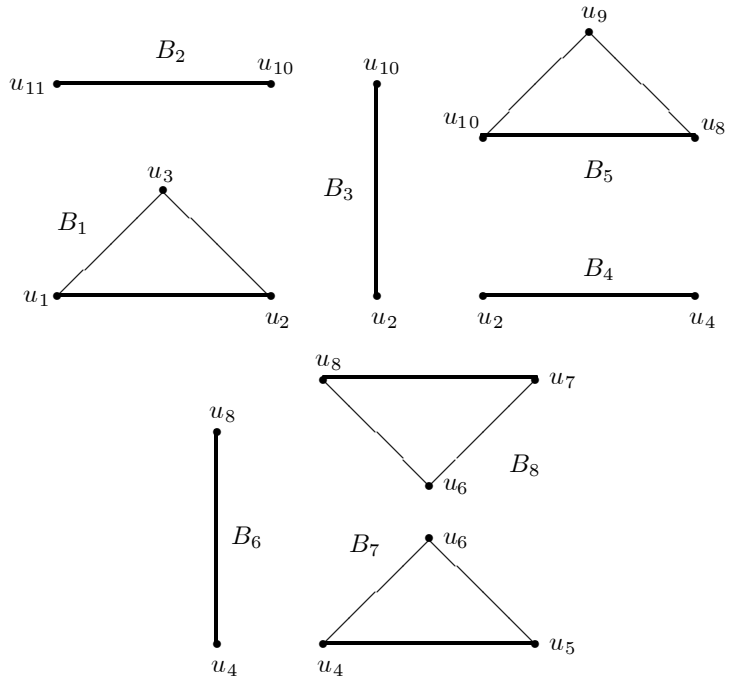

Figure III-9.

It is clear that for any two different spheres, at least one of the center coordinates is different. Thus any two distinct spheres can always be compared by the above order. Therefore the above order for the vertices of the graph is well defined.

3. Maximal Tree from a Graph

In this section, we illustrate, by means of an example, how to select a unique maximal tree from the graph which is produced for a given brain tumor by using an example. For the detailed algorithm, refer to [23].

Example III-3 Let G be the graph in Figure III-1, with a new labeling. Then $C_1(G) = \{b, c, e\}$ and $C_1^c(G) = \{a, d, f, g, h, i, j, k, l, m, n\}$. In $C_1(G)$, we have that $d(e) = 5$, $d(b) = 4$ and $d(c) = 3$. On the other hand, in $C_1^c(G)$, we have that $d(k) = 5$, $d(m) = d(n) = 3$, $d(d) = d(f) = d(g) = d(h) = d(l) = 2$, $d(a) = d(i) = d(j) = 1$. And $C_2 = \emptyset$. Thus we order the vertices as follows; $v_1 = e$, $v_2 = b$, $v_3 = c$ and $v_4 = k$, $\{v_5, v_6\} = \{m, n\}$, $\{v_7, v_8, v_9, v_{10}, v_{11}\} = \{d, f, g, h, l\}$, $\{v_{12}, v_{13}, v_{14}\} = \{a, i, j\}$. Assume that $v_5 = m$, $v_6 = n$, $v_7 = d$, $v_8 = f$, $v_9 = g$, $v_{10} = h$, $v_{11} = l$, $v_{12} = a$, $v_{13} = i$, $v_{14} = j$, which are decided by the sizes and centers of the corresponding spheres. (See Figure III-16.)

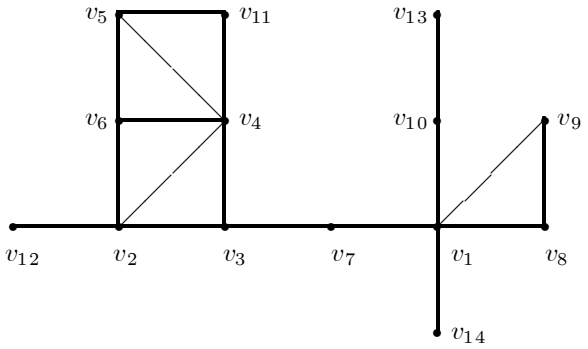

Figure III-16

For the cutvertex v_1, we keep the 5 edges attached to v_1. (See Figure III-17.)

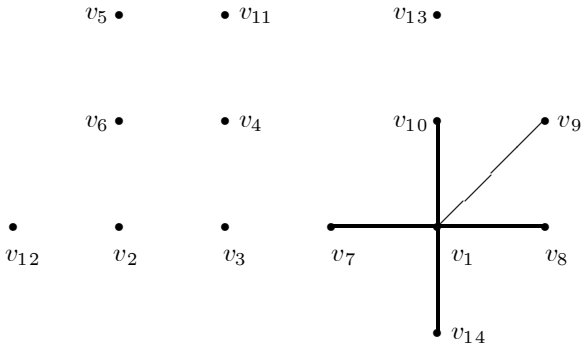

Figure III-17

Since v_2 is not adjacent to the vertex v_1, we keep all the edges attached to v_2. (See Figure III-18.)

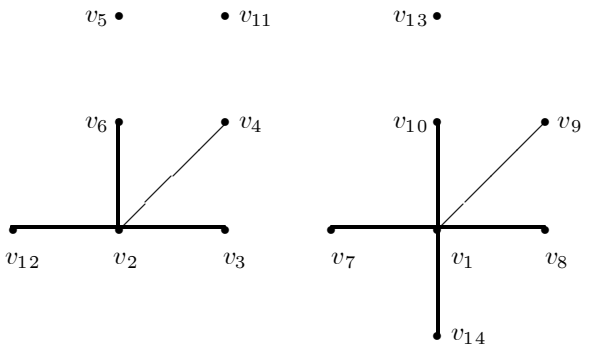

Figure III-18

Since v_3 is an adjacent vertices of v_2, the edge $\{v_3, v_4\}$ makes a circular form. Thus we keep the edge $\{v_3, v_7\}$ only. (See Figure III-19.)

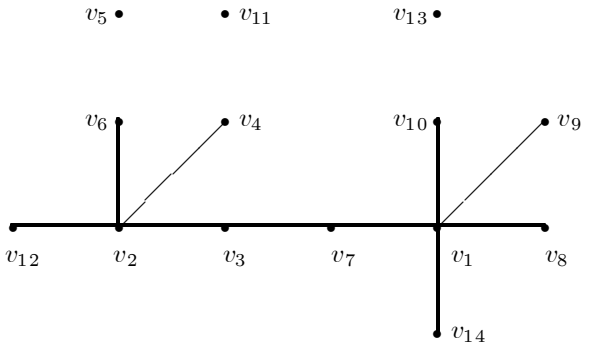

Figure III-19

For the vertex v_4, by the same reasoning, we keep only 2 edges, $\{v_4, v_5\}$ and $\{v_4, v_{11}\}$. (See Figure III-20.)

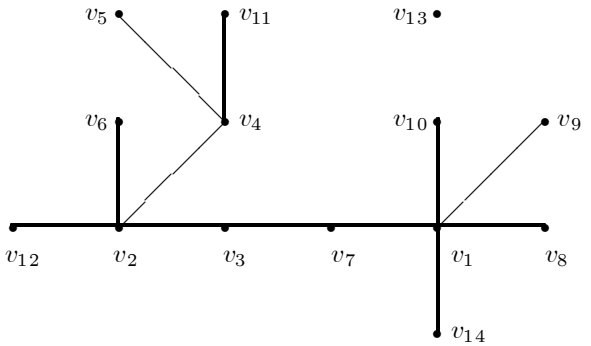

Figure III-20

For the vertices v_5, v_6, v_7, v_8, v_9, there is no 'new' edge. For the vertex v_{10}, we could keep the edge $\{v_{10}, v_{13}\}$. At this moment, the total number of edges in this

tree is 13 which is one less of the number of vertices. Therefore we have a maximal tree for the given graph. (See Figure III-21.)

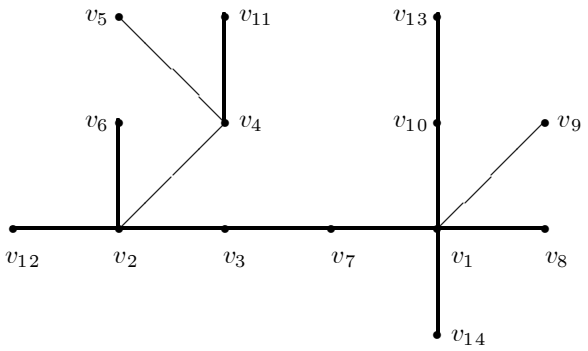

Figure III-21

For this resulting tree T, we choose the vertex sequence

$$\langle v_1, v_7, v_3, v_2, v_4, v_5, v_{11}, v_6, v_{12}, v_{10}, v_{13}, v_8, v_9, v_{14} \rangle .$$

Then $P = \langle 5, 1, 1, 3, 2, 0, 0, 0, 0, 1, 0, 0, 0, 0 \rangle$ is the *perfect degree sequence* of T.

If we are interested only in the shape of a brain tumor, without regard to physical consequences (for example, location near an eye or the brain stem, etc), then we can fully automate our program from section I, to obtain a unique tree.

For any brain tumor, we have a unique sphere packing plan by the automated program in [21] and [22], and it can be represented by a graph. Then we have a unique *perfect sequence* for the graph. That is, we can assign exactly one perfect sequence to each brain tumor. So, if two perfect sequences are distinct, then their corresponding trees, and therefore their respective corresponding graphs and sphere packings, are also distinct. That is, if two tumors are represented by distinct perfect sequences, then their corresponding trees are not isomorphic. And their respective graphs and sphere packing plans are not isomorphic. Thus, we may consider their shapes to be distinct. Therefore we have the following:

Theorem 2 *The perfect sequences are invariants of the shapes of arbitrary brain tumors.*

This work is a summary of the author's dissertation, under the direction of Beverly L. Brechner. Various parts of this work were in collaboration with different subgroups of the following people: Beverly L. Brechner, Frank Bova, Yen Chen, Mattew Harvey, Tomas Wagner, as well as additional faculty from the Brain Institute at University of Florida. This work is motivated by questions radised by Dr. Frank Bova of the McKnight Brain Institute at the University of Florida. Dr. Bova led a joint medical and mathematics research group, which included all of the mentioned people above. For more detailed results see references [19], [21], [22], [23], [24].

The Joy of Set

or

Some Combinatorial Questions Related to the Configuration of Points in Z_3^k

Mike Zabrocki
York University

Set®

The official web page for the game of *Set*® can be found at http://www.setgame.com . This site has information on how to obtain the card game, rules of the game, links to other web sites with information about the game, some mathematics and some trivia.

Advanced Set

I have written a Java version of the card game that can be played within a web page here that should work on Internet Explorer with a reasonably updated version of Java or downloaded in zip format for Macintosh OS 9 (or earlier?...It should *just* activate Apple Applet Runner). Other platforms may download the source in .tar.gz format and modify it so that it works on their system, however I haven't gotten it to work on any other computers except as an applet of Internet Explorer. So much for the platform independence of Java.

The Joy of Set

There is also an html and pdf version of a document that explains the game of set, the extended version that I have written here, and some mathematics that is associated with the game. This pdf document along with the program was written to be presented at FPSAC '01 at Arizona State University in May, 2001.

I would like to thank Andrew Rechnitzer for helpful suggestions and encouragement. I would also like to thank Carol Chang, Murray Elder, Nantel Bergeron, John Wild, and Jamal Ahmed for their advice, support, equipment use and suggestions.

1998 Steele Prizes

The 1998 Leroy P. Steele Prizes were awarded at the 104th Annual Meeting of the AMS in January in Baltimore. These prizes were established in 1970 in honor of George David Birkhoff, William Fogg Osgood, and William Caspar Graustein and are endowed under the terms of a bequest from Leroy P. Steele.

The Steele Prizes are awarded in three categories: for expository writing, for a research paper of fundamental and lasting importance, and for cumulative influence extending over a career, including the education of doctoral students. The current award is $4,000 in each category.

The recipients of the 1998 Steele Prizes are JOSEPH H. SILVERMAN for Mathematical Exposition, DORON ZEILBERGER and HERBERT S. WILF for a Seminal Contribution to Research, and NATHAN JACOBSON for Lifetime Achievement.

The Steele Prizes are awarded by the AMS Council acting through a selection committee whose members at the time of these selections were: Richard A. Askey, Ciprian Foias, H. Blaine Lawson Jr., Andrew J. Majda, Louis Nirenberg, Jonathan M. Rosenberg, and John T. Tate.

The text that follows contains for each award the committee's citation, a brief biographical sketch, and the recipient's response upon receiving the award.

Steele Prize for Mathematical Exposition: Joseph H. Silverman

Citation

The Leroy P. Steele Prize for Mathematical Exposition is awarded to Joseph H. Silverman of Brown University for his books *The Arithmetic of Elliptic Curves*, Graduate Texts in Mathematics, vol. 106, Springer-Verlag, New York-Berlin, 1986, ISBN 0-387-96203-4; and *Advanced Topics in the Arithmetic of Elliptic Curves*, Graduate Texts in Mathematics, vol. 151, Springer-Verlag, New York, 1994, ISBN: 0-387-94328-5. The review of the first of these volumes in *Math. Reviews* by Robert S. Rumely, MR 87g:11070, begins as follows:

> This well-written book covers the basic facts about the geometry and arithmetic of elliptic curves, and is sure to become the standard reference in the subject. It meets the needs of at least three groups of people: students interested in doing research in Diophantine geometry, mathematicians needing a reference for standard facts about elliptic curves, and computer scientists interested in algorithms and needing an introduction to elliptic curves. For a long time one of the standard references for elliptic curves has been the survey article of J. W. S. Cassels [J. London Math. Soc. **41** (1966), 193–291; MR 33 #7299; errata; MR 34 #2523]. In its choice of topics this book may be viewed as an amplification of Cassels' article, with technical details filled in, much more motivation, and an excellent set of exercises.

Cassels himself reviewed the book in the *AMS Bulletin* [*Bull. Amer. Math. Soc.* (N.S.) **17** (1987), 148–149]. The review is short, but to the point. It concludes: "In the reviewer's opinion [Silverman]'s book fills the gap admirably. An old hand is hardly the best judge of a book of this nature, but reports of graduate students are equally favorable."

The review of Silverman's second volume in *Math. Reviews* by Henri Darmon, MR 96b:11074, is even more enthusiastic. It says:

> Since its publication almost 10 years ago, Silverman's book *The Arithmetic of Elliptic Curves* has become a standard reference, initiating thousands of graduate students (the reviewer among them) to this exciting branch of arithmetic geometry. The eagerly awaited sequel, *Advanced Topics in the Arithmetic of Elliptic Curves*, lives up to the high expectations generated by the first volume....After reading *Advanced Topics* with much pleasure, we can only hope for a third volume....

In short, Silverman's volumes have become standard references on one of the most exciting areas of algebraic geometry and number theory.

Biographical Sketch

Joseph H. Silverman was born on March 27, 1955, in New York. He received his Sc.B. from Brown University (1977) and his M.A. (1979) and Ph.D.

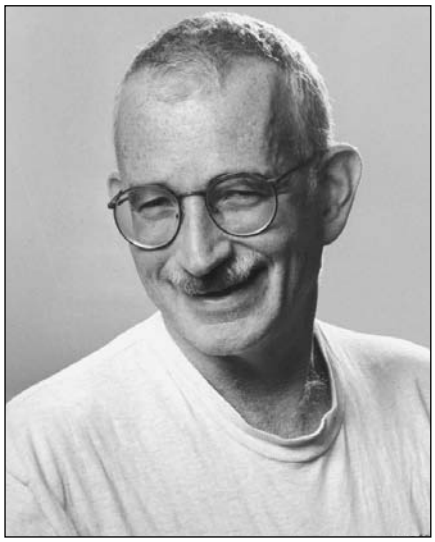
Herbert S. Wilf



Temple University News Bureau.

Doron Zeilberger

(1982) from Harvard University. He began his career as a Moore Instructor at MIT (1982–86), followed by associate professorships at Boston University (1986–88) and Brown University (1988–91). Since 1991 he has been a professor of mathematics at Brown University.

Professor Silverman has been an NSF Post-Doctoral Fellow (1983–86) and an Alfred P. Sloan Foundation Fellow (1987–91) and is a recipient of an MAA Lester Ford Award (1994). In addition to the two books cited in his Steele Prize, Professor Silverman has written *Rational Points on Elliptic Curves* (jointly with John Tate, 1992) and *A Friendly Introduction to Number Theory* (1996), as well as numerous research articles. He has also coorganized two conferences, "Arithmetic Geometry" (Storrs, 1984) and "Fermat's Last Theorem" (Boston, 1995) and coedited the proceedings. His research interests include number theory, arithmetic geometry, elliptic curves, and arithmetic aspects of dynamical systems.

Response

I am deeply honored to receive a Steele Prize for my two books on elliptic curves. When I wrote the first volume shortly after receiving my Ph.D., my aim was to write the book that I wished had been available when I was a graduate student. It has given me great pleasure to see it fulfilling that purpose for other students over the past decade. In the original outline for that first (and, I assumed, solitary) book, there were twenty topics to be covered. Ten topics and 400 pages later, the publisher and I agreed that the book was finished, but as a sop to the reader and to my conscience, I included a short appendix briefly describing the ten omitted topics. This foolish act on my part was considered by many people to be a tacit promise that someday there would be a second volume. Eventually the second volume was written, and not surprisingly, its 500 pages only sufficed to cover half of the remaining material!

No writer operates in a vacuum. I would like to thank the many people from whom I learned about the beautiful theory of elliptic curves, including John Tate, Barry Mazur, Serge Lang, the members of the Harvard Elliptic Curves Seminar (1977–82), and many other writers, colleagues, students, and friends far too numerous to catalog. My books could never have been written without their encouragement and inspiration.

Steele Prize for a Seminal Contribution to Research: Herbert S. Wilf and Doron Zeilberger

Citation

The Leroy P. Steele Prize for Seminal Contribution to Research is awarded to Herbert S. Wilf, Thomas A. Scott Professor of Mathematics, of the University of Pennsylvania, and Doron Zeilberger of Temple University for their paper *Rational functions certify combinatorial identities*, J. Amer. Math. Soc. **3** (1990), 147–158.

New mathematical ideas can have an impact on experts in a field, on people outside the field, and on how the field develops after the idea has been introduced. The remarkably simple idea of the work of Wilf and Zeilberger has already changed a part of mathematics for the experts, for the high-level users outside the area, and for the area itself. George Andrews, one of the world's leading experts on q-series (which arise, for example, in statistical mechanics), wrote the following about the method of Wilf and Zeilberger: "In my proof of Capparelli's conjecture, I was completely guided by the Wilf-Zeilberger method, even if I didn't use Doron's program explicitly. I couldn't have produced my proof without knowing the principle behind 'WZ'. It is a really powerful result and does indeed merit the Steele Prize."

Donald Knuth, winner of the Steele Prize in 1986 for his books on *The Art of Computer Programming,* has written the following in his foreword to the book *A=B* by Marko Petkovšek, Wilf, and Zeilberger:

> Science is what we understand well enough to explain to a computer. Art is everything else we do. During the past several years an important part of mathematics has been transformed from an Art to a Science. No longer do we need to get a brilliant insight in order to evaluate sums of binomial coefficients, and many similar formulas that arise frequently in practice; we can now follow a mechanical procedure and discover the answers quite systematically.
>
> I fell in love with these procedures as soon as I learned them, because they worked for me immediately. Not only did they dispose of sums that I had wrestled with long and hard in the past, they also knocked off two new problems that I was working on at the time I first tried them. The success rate was astonishing.
>
> Notice that the algorithm doesn't just verify a conjectured identity *A=B*. It also answers the question "What is A?", when we haven't been able to formulate a decent conjecture.

Computer packages have been written to make it possible for others to use the Wilf-Zeilberger idea. Doron Zeilberger has written one. This is the "package" George Andrews mentioned in his quote above. Tom Koornwinder in Amsterdam has a variant, as does Wolfram Koepp in Berlin and Peter Paule in Linz. Marko Petkovšek has extended this work from terminating series to nonterminating series, and work has recently been done on multisums using similar but not identical methods. As offshoots of the Wilf-Zeilberger method become built into computer algebra systems, many people will be using it without being aware it is what makes their calculations possible.

Biographical Sketch: Herbert S. Wilf

Herbert Wilf has written several books, including *Combinatorial Algorithms* with Albert Nijenhuis; *Algorithms and Complexity*; *Generating Functionology*; and, most recently, *A=B* with Marko Petkovšek and Doron Zeilberger. He has been the editor-in-chief of the *American Mathematical Monthly*, 1987–91; was co-founder with Donald Knuth of the *Journal of Algorithms*; and was co-founder with Neil Calkin and is co-editor-in-chief of the *Electronic Journal of Combinatorics*, a peer-reviewed free electronic research journal on the WWW, which is now publishing its sixth volume and is in its fourth year of publication. He received in 1996 the Haimo Award of the Mathematical Association of America for Distinguished Teaching of College or University Mathematics, and he is especially proud to have supervised the dissertations of more than twenty Ph.D. students. The University of Pennsylvania recently named him Thomas A. Scott Professor of Mathematics.

He was born in 1931 in Philadelphia, did undergraduate work at MIT, and got his Ph.D. from Columbia University in 1958. His first faculty position was at the University of Illinois, and he came to the University of Pennsylvania in 1962, where he has been ever since. He has been a Visiting Professor at Imperial College of the University of London, Stanford University, and Rockefeller University, where he was a Guggenheim Fellow.

Response: Herbert S. Wilf

I am deeply honored to receive the Leroy P. Steele Prize. I might say that doing this research was its own reward—but it's very nice to have this one too! My thanks to the Selection Committee and to the AMS.

Each semester, after my final grades have been turned in and all is quiet, it is my habit to leave the light off in my office, leave the door closed, and sit by the window catching up on reading the stack of preprints and reprints that have arrived during the semester. That year, one of the preprints was by Zeilberger, and it was a 21st-century proof of one of the major hypergeometric identities, found by computer, or more precisely, found by Zeilberger using his computer. I looked at it for a while, and it slowly dawned on me that his recurrence relation would assume a self-dual form if we renormalize the summation by dividing first by the right-hand side. After that normalization, the basic "WZ" equation F(n+1,k)-F(n,k)=G(n,k+1)-G(n,k) was in the room with me, and its self-dual symmetrical form was very compelling. I remember feeling that I was about to connect to a parallel universe that had always existed but which had until then remained well hidden and that I was about to find out what sorts of creatures lived there. I also learned that such results emerge only after the efforts of many people have been exerted, in this case, of Sister Mary Celine Fasenmyer, Bill Gosper, Doron Zeilberger, and others. Doing joint work with Doron is like working with a huge fountain of hormones — you might get stimulated to do your best or you might drown. In this case I seem to have lucked out. It was a great adventure.

Biographical Sketch: Doron Zeilberger

Doron Zeilberger was born on July 2, 1950, in Haifa, Israel, to Ruth (Alexander) and Yehudah Zeilberger. He received his Ph.D. in 1976 from the Weizmann Institute of Science (as a student of

Harry Dym (a student of Henry McKean (a student of William Feller (a student of Richard Courant (a student of David Hilbert))))).

In 1979 he married Jane D. LeGrange (Ph.D., physics, Illinois, 1980, currently at Lucent Technology Bell Labs). Their children are Celia (b. 1983), Tamar (b. 1986), and Hadas (b. 1990).

In January 1996 he delivered the second Gillis Memorial Lecture at the Weizmann Institute.

Including this Steele Prize, his earnings to date from mathematical prizes are 2600 U.S. dollars ((1/2)(4000)+ 500 [MAA's 1990 L. R. Ford Award] + (1/2)50 [from Dick Askey and George Andrews for a proof of the q-Dyson conjecture, joint with Dave Bressoud] + (1/2)50 [from Dick Askey for a proof of the G2 case of Macdonald's conjecture, shared with Laurent Habsieger] +50 [from Dick Askey for a proof of the G2-dual case of Macdonald's conj.]), 10 bottles of wine [from Xavier Viennot for a certain tree-bijection], and one book [from Mark Pinsky, for a "calculus problem"].

Response: Doron Zeilberger

[Generic thanks and expressions of astonishment.]

At 11:05 p.m., December 24 (sic!), 1988, Herb Wilf called me up, and with Wilfian enthusiasm told me how the beautiful one-line proofs of certain classical identities, generated by my beloved computer, Shalosh B. Ekhad, could be made even prettier and how to obtain as a bonus a "dual identity" that is often much more interesting than the one originally proved. Thus was born WZ theory.

WZ theory has taught me that computers, by themselves, are not yet capable of creating the most beautiful math. Conversely, humans do much better math in collaboration with computers. More generally, combining different and sometimes opposite approaches and viewpoints will lead to revolutions. So the moral is: Don't look down on any activity as inferior, because two ugly parents can have beautiful children, and a narrow-minded or elitist attitude will lead nowhere.

We live in the great age of the democratization of knowledge and even of that elitist ivory tower called mathematics. Whoever would have believed thirty years ago that a 1988 Steele Prize would go to Rota for his work in "combinatorics" (a former slum), and whoever would have believed ten years ago that a 1998 Steele Prize would go to W and Z for their work on "binomial coefficients identities" (hitherto a slum squared).

The computer revolution, and especially the World Wide Web, is quickly making mathematics accessible and enjoyable to many more people. Especially commendable are the wonderful Web site of Eric Weisstein's "Eric Treasure Troves", Steve Finch's pages on mathematical constants, the Sloane-Plouffe On-Line Encyclopedia of Integer Sequences, Simon Plouffe's "Inverse Symbolic Calculator", and St. Andrews University's MacTutur site on the history of mathematics.

It is very important to make information, in particular mathematical information, freely accessible. The pioneering, and extremely successful, *Electronic Journal of Combinatorics*, created by Herb Wilf in 1994, should be emulated. It is very regrettable that the American Mathematical Society has subscription-only electronic journals and that the electronic versions of its paper journals are only available to paper subscribers. It is a disgrace that MathSciNet is only viewable for paying customers, thereby making its contents unsearchable by public search-engines.

On the positive side, the AMS has been very efficient in taking advantage of the electronic revolution, and the free ERA-AMS, under the leadership of Svetlana Katok, is a real gem!

I am really happy, not only for myself and Herb, but also because of the recognition that the field of hypergeometric series (alias binomial-coefficients identities) is hereby granted. There are so many giants on whose shoulders we are standing. Guru Dick Askey, q-Guru George Andrews, and Guru Don Knuth who preached the gospel from the continuous and discrete sides. Sister Celine Fasenmyer, a non-standard, yet very tall, giant. Hacker Bill Gosper who deserves this prize even more, and many others.

I should also mention our collaborators in this area: Gert Almkvist and Marko Petkovšek, and the beautiful work of Tewodros Amdeberhan, Frederic Chyzak, J. Hornegger, Bruno Gauthier, Ira Gessel, Wolfram Koepf, Christian Krattenthaler, John Majewicz, Istvan Nemes, John Noonan, Sheldon Parnes, Peter Paule, Bruno Salvy, Marcus Schorn, Volker Strehl, Nobuki Takayama, P. Verbaeten, Kurt Wegschaider, and Lily Yen.

Finally, I must mention my main influencers, in roughly chronological order: my terrific seventh-grade math teacher, Devorah Segev, and my great eighth-grade history teacher (and principal), Matityahu Pines. My cousin Mati Weiss, who showed me Joe Gillis's *Gilyonot leMatematika*. Joe Gillis, who, in my early teens, first made me into a mathematician through his *Gilyonot leMatematika*. My advisor, Harry Dym, who initiated me into research. My god-advisor, Dick Duffin, who discretized me. Leon Ehrenpreis, who dualized me. Joe Gillis (again!), who deranged me. Gian-Carlo Rota, who umbralized me. Dick Askey, who hypergeometrized me. George Andrews, who q-ified me. Herb Wilf (the same Herb!), who combinatorized me. Dominique Foata, who bijectified me. Jet Wimp, who asymptotized me. Xavier Viennot, who Schutzenbergerized me. Marco Schutzenberger, who formalized me. Bruno Buchberger, who basically standarized [grobnerized] me. Gert Almkvist, who integralized me, and Pierre Cartier, who Bourbakised me. Let them all be blessed!

Nathan Jacobson

Steele Prize for Lifetime Achievement: Nathan Jacobson

Citation

The Leroy P. Steele Prize for Lifetime Achievement is awarded to Nathan Jacobson, Henry Ford II Professor of Mathematics, Emeritus, of Yale University for his many contributions to research, teaching, exposition, and the mathematical profession. In research he is known primarily for his contributions to ring theory and to the theory of Lie algebras and Jordan algebras. Among the concepts or theorems that bear his name are the Jacobson radical (of a ring), the Jacobson topology (on primitive ideals), and the Jacobson-Morosov Theorem (in Lie theory). In exposition Jacobson is known for quite a number of important books, especially *Lectures in Abstract Algebra* (3 volumes, Van Nostrand, 1951, 1953, and 1964; reprinted by Springer, 1975), later superseded by *Basic Algebra I and II* (Freeman, 1974 and 1980, 1975 and 1989); *Structure of Rings* (AMS Colloquium Publications, vols. 37 and 39, 1956 and 1968); and *Lie Algebras* (Wiley-Interscience, 1962; reprinted by Dover, 1979).

Jacobson served as president of the AMS in 1971–72 and as vice-president of the International Mathematical Union in 1972–74. He received an honorary D.Sc. degree from the University of Chicago in 1972. The list of authors of *Algebraists' Homage*, volume 13 of the AMS Contemporary Mathematics series dedicated to Jacobson on the occasion of his retirement in 1981, includes dozens of the world's greatest algebraists. Few mathematicians have been as productive over such a long career or have had as much influence on the mathematical profession as Jacobson.

Biographical Sketch

Born in Warsaw, Poland, in 1910, Nathan Jacobson immigrated to the United States with his family at the age of seven and grew up in Mississippi and Alabama. He graduated from the University of Alabama in 1930 and embarked upon his graduate studies in mathematics at Princeton University, where he received his Ph.D. in 1934. Professor Jacobson taught at Bryn Mawr College, the University of North Carolina, and the Johns Hopkins University for several years before being appointed professor at Yale University in 1947. In 1963 he was named the Henry Ford II Professor of Mathematics at Yale, a position he held until his retirement in 1981. As a visiting professor he lectured at universities all over the world, including France, Israel, India, China, Japan, and the former Soviet Union.

The author of seventeen books, as well as numerous papers, he is renowned for his contributions to the theory of associative rings, Lie algebras, Jordan algebras, and topological algebra. Presently retired and living in New Haven, Connecticut, Professor Jacobson retains a keen interest in the world of mathematics.

Response

I am greatly honored and deeply moved to have been chosen for the Leroy P. Steele Prize for Lifetime Achievement in Mathematics. It is especially gratifying for me to be honored in this way by the American Mathematical Society.

A lifetime achievement award is particularly meaningful for someone like me who has had, both professionally and personally, such a rich, rewarding, and, yes, long life. My mathematical career and the contributions you have cited in research, writing, and teaching have spanned a period of over sixty years. During that time it has been my pleasure to come in contact with many eminent mathematicians both here in the United States and throughout the world. As their work has stimulated and inspired me, so it is my hope that my own efforts, especially those in ring theory and the theory of Lie and Jordan algebras, will stimulate and inspire the research, writing, and teaching of those who come after.

There are many individuals whom it would be appropriate to thank, too many to name without the risk of omitting some. Nevertheless, I wish to acknowledge a special debt to my thesis advisor and mentor, J. H. M. Wedderburn. I also wish to express my gratitude to my fifty former thesis students who chose me as their mentor. Yale University should be singled out for giving me nearly half a century of support and a fertile academic environment in which to work. Finally, I want to thank my deceased wife, Florie, for her devotion and sparkling companionship over the course of a long and happy marriage. I could never have achieved as much as I did without her.

Once again, I extend my sincere gratitude to the American Mathematical Society, in particular to the members of the Steele Prize Committee, for this prestigious award. I will cherish this honor for the rest of my days. Thank you.

The Electronic Journal of Combinatorics

Abstract for R28 of Volume 8(1), 2001

Doron Zeilberger

The Umbral Transfer-Matrix Method. IV. Counting Self-Avoiding Polygons and Walks

This is the fourth installment of the five-part saga on the Umbral Transfer-Matrix method, based on Gian-Carlo Rota's seminal notion of the umbra. In this article we describe the Maple packages USAP, USAW, and MAYLIS. USAP automatically constructs, for any specific r, an Umbral Scheme for enumerating, according to perimeter, the number of self-avoiding polygons with $\leq 2r$ horizontal edges per vertical cross-section. The much more complicated USAW does the analogous thing for self-avoiding walks. Such Umbral Schemes enable counting these classes of self-avoiding polygons and walks in polynomial time as opposed to the exponential time that is required by naive counting. Finally MAYLIS is targeted to the special case of enumerating classes of saps with at most two horizontal edges per vertical cross-section (equivalently column-convex polyominoes by perimeter), and related classes. In this computationally trivial case we can actually *automatically* solve the equations that were *automatically* generated by USAP. As an example, we give the first *fully computer-generated* proof of the celebrated Delest-Viennot result that the number of convex polyominoes with perimeter $2n+8$ equals $(2n+11)4^n - 4(2n+1)!/n!^2$.

L'Encyclopédie Électronique des Suites Entières

(English)

Table des matières:

-  **Pour rechercher une suite,** cliquez sur l'exemple, tapez votre suite et cliquez "Chercher":

  1,2,3,6,11,23,47,106,235 [Chercher]

  Explications des abréviations utilisées

-

Feuilleter la table. Voulez-vous voir une suite choisie au hasard dans la base de données de l'Encyclopédie ? Oui

Ou une des «meilleures» suites ? Le dessus du panier ? (Je suis désolé, mais les réponses seront en anglais.)

- **Pour chercher une suite à partir de son numéro dans la table,** cliquez sur l'exemple, tapez le numéro que vous voulez et cliquez sur le bouton "Chercher":

4001 Chercher

- **Pour chercher un mot dans la table**, cliquez sur l'exemple, tapez le(s) mot(s) que vous voulez et cliquez sur le bouton "Chercher":
(N'utilisez pas de "joker"; pas de distinction minuscule/majuscule; seules les 512 premières occurences sont affichées ; mais remarquez que vous pouvez toujours télécharger la table complète.)

Commutative rings Chercher

Proposer une nouvelle suite ou envoyer un commentaire sur une suite existante.

Si votre suite n'est pas dans la table (et est intéressante !) envoyez-la moi et je l'ajouterai (probablement). Pourquoi proposer une nouvelle suite ? C'est une façon de faire reconnaître votre priorité, votre nom est immortalisé, et la prochaine personne qui tombera sur cette suite vous sera sans doute reconnaissante.

Ajoutez une courte description et si possible assez de termes pour remplir trois lignes à l'écran. J'ai besoin d'au moins 4 termes.

Notez que pour être ajoutée à la base de donnée, la suite doit

- être constituée d'entiers (bien que quelques suites de fractions aient été incluses, numérateurs et dénominateurs séparés)
- être infinie - bien qu'il y ait de nombreuses exceptions à cette règle
(on trouve même dans la table diverses listes d'arrêts de bus)
- être intéressante

Au cours des deux années écoulées, de nouvelles suites m'ont été envoyées au rythme de 30 par jour ou 10.000 par an. C'est merveilleux mais je passe vraiment trop de temps à les formater. C'est pourquoi je demande désormais que pour proposer une nouvelle suite l'on utilise soit le formulaire ici, soit que l'on mette soi-même la suite au format (ou utilisez le programme Maple ou programme Mathematica pour formater une suite).

Envoi d'une nouvelle suite ou un commentaire sur une suite existante: (Remplacez les textes d'exemple par vos informations.)

Indiquez s'il vous plait votre nom (obligatoire): Jane H. Smith

et votre adresse électronique (obligatoire): smith@xxx.yyy.com

---

◉ Nouvelle suite ○ Commentaire sur la suite existante numéro: [ ] (e.g. A123456)

Pour une suite nouvelle ou une extension d'une suite existante, donnez les premiers termes ici.
(Le mieux serait d'avoir assez de termes pour remplir 2 ou 3 lignes à l'écran. Vous pouvez séparer les nombres par des espaces ou des virgules.)

1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377

Donnez une brève description de la suite en anglais (obligatoire pour une suite nouvelle):

The number of different graphs on n unlabeled nodes.

Quelle est la valeur de l'indice ou du paramètre pour le terme de départ ?
(Par exemple, si la suite compte le nombre de graphes à n sommets ayant une propriété donnée, où débute n ? Si il s'agit d'une suite récurrente, quel est l'indice du premier terme ? Si il n'y a pas de choix évident, indiquez 0.)

0

Si vous en connaissez une, donnez une formule, une récurrence, une fonction génératrice, ...:

a(n) = 2*a(n-1) + 3; generating function = 1/(exp(x)-1).

Donnez au maximum 3 références, publiées ou non:

M. Jones, On the enumeration of graphs, American Mathematical Monthly,
Vol. 100 (1993), pp. 1-25.

M. Jones, Further remarks on the enumeration of graphs, preprint, 2001.

Donnez au maximum 3 pointeurs URL des document sur cette suite. Les lignes **doivent** être de la forme montrée ici: J. H. Smith, Perfect Numbers

Informations et commentaires:

Références croisées à d'autres suites ?

Cf. A123456, A123457.

Choisir les mots-clef (pour de plus amples informations, suivez le lien):

Envoyer Effacer

- **Devinettes:**
  Pouvez-vous trouver la loi qui donne ces suites ?
  À mon avis, dans ce genre de problèmes il faut toujours donner au moins 10 termes.

- Celle-ci est parue dans le New York Times:
  2, 3, 3, 5, 10, 13, 39, 43, 172, 177, ... Réponse

- 5, 5, 1, 5, 101, 9, 0, 6, 5, 509, ...
  Indice: écrivez un, deux, trois, quatre, cinq, six, sept, huit, neuf, dix, ... et pensez en Romain !
  Ils sont fous ces romains !

- Tiré du magazine **Chess Life**, on dit que cette séquence a fait sécher le champion du monde d'échecs (sauf que je suis sûr que l'on ne lui avait pas donné 10 termes):
  7, 9, 40, 74, 1526, 5436, 2323240, 29548570, 5397414549030, 873117986721660, ...
  Echec ?

- Tout le monde connaît les nombres impairs, suite A005408.
  Les nombres apparés sont bien moins connus (laissez-vous guider par le nom !):
  1, 3, 5, 6, 8, 10, 18, 20, 23, 25, ... Pour voir !

- Un peu dans le même esprit, il y a les reimerps (ou **emirps**):
  13, 17, 31, 37, 71, 73, 79, 97, 107, 113, ... Relou !

- Classique et élégant:
  1, 2, 2, 3, 3, 4, 4, 4, 5, 5, 5, 6, 6, 6, 6, 7, 7, 7, 7, 8, 8, 8, 8, 9, 9, 9, 9, ... S.V.P.

- Et celle-là ?
  1, 3, 7, 12, 18, 26, 35, 45, 56, 69, 83, ... Je sèche !
  Hmmm ! Toujours pensif ? J'ai vu des gamins de neuf ans qui la trouvaient plus vite et les doigts dans le nez.

Celle-ci est facile pour les adolescents doués, ou bien si vous l'avez déjà rencontrée, sinon...
2, 12, 1112, 3112, 132112, 1113122112, 311311222112, 13211321322112,
111312211312111322112, 31131122211311123113322112, ... Rien ?

L'analyse magistrale des propriétés asymptotiques de cette suite par John Conway mérite d'être lue - cf. la référence indiquée.

❍

Très facile:
1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25... Bien sûr !

❍

Pas si difficile quand on la prend du bon côté :
1, 2, 6, 20, 70, 252, 924, 3432, 12870, 48620, ... Ah bon ?

- **L'interrogation par courrier électronique et "Superseeker"**. Il y a deux services de courrier électronique pour identifier les suites:

  Le premier d'entre eux, **sequences@research.att.com**, fait une simple recherche de la suite dans la base de données. Il suffit d'envoyer une ligne du genre

  lookup 1 2 5 14 42 132 429 [pas de virgule !]

  par exemple. On peut inclure jusqu'à cinq recherches par message. Ce système est très utile quand le Web est encombré.
  Pour de plus amples informations, suivez le lien.

  Le second service, **superseeker@research.att.com**, est un programme d'identification bien plus puissant, il fait vraiment tout son possible pour analyser la suite. Essayez le message

  lookup 1 1 2 5 14 42 132 429 1430 4862 [pas de virgule !]

  par exemple. Une seule recherche par message. Pour de plus amples informations, suivez le lien.

- **Remarque.** Cette version française ne correspond plus à la version anglaise. Des changements à la version anglaise étant prévus prochainement, j'attends qu'ils soient terminés avant de mettre à jour la version française.

- **Remerciements.** Un très grand nombre de gens ont contribué à cette table, et il est impossible de les remercier tous individuellement. Leur noms peuvent être lus dans les lignes "%A". Je suis

particulièrement reconnaissant à Mira Bernstein ("mb"), Henry Bottomley, Christian Bower (bowerc@usa.net), John Conway ("jhc"), Patrick De Geest, Patrick Demichel, Steven Finch, Erich Friedman, Olivier Gerard ("og"), Richard K. Guy ("rkg"), Vladeta Jovovic (vladeta@Eunet.yu), Antti Karttunen, Clark Kimberling, Simon Plouffe ("sp"), Larry Reeves (larryr@acm.org), James Sellers, Jeffrey Shallit ("jos"), Michael Somos, Eric Weisstein, David W. Wilson ("dww") [wilson@ctron.com] and Robert G. Wilson V ("rgwv"), qui ont fait des apports majeurs ces dernières années.

Demonstration of the

On-Line Encyclopedia of Integer Sequences

(Start)

- This sequence of pages will show some of the ways that the **On-Line Encyclopedia of Integer Sequences** can be used.

- Let's begin right away with an example of a beautiful sequence from the database:

```
ID Number: A000037
Sequence:  2,3,5,6,7,8,10,11,12,13,14,15,17,18,19,20,21,22,23,24,26,27,
           28,29,30,31,32,33,34,35,37,38,39,40,41,42,43,44,45,46,47,48,
           50,51,52,53,54,55,56,57,58,59,60,61,62,63,65,66,67,68,69,70,
           71,72,73,74,75,76,77,78,79,80,82,83,84,85,86,87,88,89,90,91,
           92,93,94,95,96,97,98,99
Name:      Numbers that are not squares (note the remarkable formula
                for the n-th term).
Example:   For example note that the squares 1, 4, 9, 16 are not
included.
References A. J. dos Reis and D. M. Silberger, Generating nonpowers by
formula,
                Math. Mag., 63 (1990), 53-55.
Formula:   a(n) = n + [1/2 + sqrt(n)].
Maple:     A000037:=n->n+floor(1/2+sqrt(n));
Mma:       Complement[Range[100], #^2 & /@ Range[IntegerPart[Sqrt
[100]]]]
See also:  Cf. A007412, A000005, A000290, A059269.
Keywords:  easy,nonn,nice
Authors:   njas, sp
```

Note the astonishing formula for the n-th term.

- To follow the sequence of pages, click only the direction buttons  at the bottom of the pages. (If you click on any of the active links you will have to use your browser's "Back" button to return here.)

- Although these demonstration pages are in English, note that there is also a **French version** of the database.

- The main URL for the database is **http://www.research.att.com/~njas/sequences/**.

- The sequence contains the following pages:

Click the single right arrow to go to the next page.

Short Index to On-Line Encyclopedia of Integer Sequences

Click on the following to reach that section of the index.

- A highly selective index to the **On-Line Encyclopedia of Integer Sequences.**
- The principal sequences are marked by asterisks (*). See also the list of **"core" sequences.**
- The goal here is to try to group the principal sequences into categories, to make it easier to locate sequences dealing with a particular topic.
- If you don't find what you are looking for here, you can always **search** the database for a particular word, or even look at the **full database**.
- Entries with a double colon (::) are from the index to the 1995 book **The Encyclopedia of Integer Sequences**, by N. J. A. Sloane and Simon Plouffe. Some of these entries may now be out of date.
- Suggestions for additional entries will be welcomed.

Sequences That Need Extending

Want to help? The following sequences in the the On-Line Encyclopedia of Integer Sequences need extending
(but please read the **remarks** below the list)!

IMPORTANT: Thousands of people use the sequence database every day.
Please take **great care** that the terms you send are absolutely correct.
The standards are those of a mathematics reference work.

If possible please use the **form** when sending extensions or comments.

For other ways in which you could help, please see the file

Remarks

- All of the above sequences need extending: click on the sequence number to see the current version.
- **IMPORTANT:**

  Thousands of people use the sequence database every day. Please take **great care** that the terms you send are absolutely correct. The standards are those of a mathematics reference work.

- **Sending in an extension.**
  - If possible please use the **form** when sending extensions or comments.
  - Ideally I would like to get enough terms for each sequence to fill about three lines on the screen. Failing that even a single extra term is always welcome.
  - Please be sure to specify the sequence number in any message.
  - It is also a good idea to give the first few terms as well as the terms before that come before the new terms, to avoid any confusion. It is very easy to type A045912 when you mean A049512, and giving the first few terms of the sequence helps to detect such errors!
- **What will be needed.**
  - Some of these sequences can be calculated from the formula, recurrence or generating function given in the description.
  - Other sequences will require going to a library, to look up the formula or recurrence given in the references for the sequence (sometimes a reference will explicitly list more terms, which the person who contributed the sequence did not copy down).

- Some sequences will require that you write a program to work them out - for instance to count the structures of a certain kind.

- Some of the sequences will be very hard to extend. On the other hand there's more glory in extending them.

- All contributions will be acknowledged.

• Computer programs.

If you can generate the sequence with a few lines of code in one of the standard language, please send the program too. I am trying to give computer code to generate sequences whenever possible.

• Updates.

- The database is usually updated every few days, often every day, so if you are working on a sequence for a while, it is a good idea to recheck it to make sure no one else has extended it. This file is automatically updated with the main table.

- Please send email to njas@research.att.com if there is a sequence on the above list that should not be there - for example if there are already enough terms to fill three lines, if no more terms exist in the sequence, or if the next term is more than 10^80.

• Other problems.

See if you can improve any of the known lower bounds on **constant weight codes.** Many of them are extremely weak!

Sending in a New Sequence or a Comment on an Existing Sequence to

The On-Line Encyclopedia of Integer Sequences

If your sequence was not in the database and is interesting, please send it to me, and I will (probably) add it!

Reasons for sending in your sequence:

- This stakes your claim to it
- Your name is immortalized
- The next person who stumbles across it will be grateful to you

IMPORTANT: Thousands of people use the sequence database every day.
Please take **great care** that the terms you send are absolutely correct.
The standards are those of a mathematics reference work.

Include a brief description and if possible enough terms to fill 3 lines on the screen. I need a minimum of 4 terms.

Note that, to be included in the database, the sequence should

- consist of integers (though some sequences of fractions have entered by numerator and denominator separately)
- be infinite - though there are many exceptions to this rule (even various sequences of subway stops are in the table now)
- be interesting

I regret that because of the number of sequences received (an average of over 30 **new** sequences a day for the past 2 years, or 10000 a year), new sequences cannot be accepted unless they are in the internal format used in the database.

There are 3 ways to put sequences into this format:

- Use the Maple or Mathematica formatting scripts provided.
- Format the sequences yourself using the information in the help file. There are also over 60000 examples in the database for you to imitate!

  If you are planning to submit a series of sequences and would like some A-numbers so you can format them and get the cross-references right, click **here!**
- Use the following form.

To send in a New Sequence or a Comment on an existing sequence: (Please replace these artificial entries with your text. Click **here** to clear form.)

Your name (required): Jane H. Smith

Email address (required): Smith@xxx.yyy.com

Email addresses will be disguised by replacing @ by (AT) when they appear in the database.
If you don't want your email address to appear at all in the database then say so in one of the windows.
In that case, however, please give a link to your home page in one of the "links" windows
- enter a line that looks something like this:
J. H. Smith, Home Page

◉ **New sequence** (without an A-number)

○ **New sequence (with an A-number from the dispenser)** (e.g. A123456)

○ **Comment** on existing sequence number (e.g. A123456)

For a new sequence or extension of an old sequence, give the initial terms here:

Please give a few terms even if you are sending a comment, as a check.
For a new sequence, ideally I would like to get enough terms to fill 2 or 3 lines on the screen.
The entries may be separated by commas or spaces.

1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377

Brief description or definition of sequence (required for a new sequence):

The number of different graphs on n unlabeled nodes.

What is the value of the "index" or "subscript" of the initial term?
(For example, if the sequence counts graphs on n nodes with some property, what is the first value of n?)

0

Give **formula**, **recurrence** or **generating function** if known:

a(n) = 2*a(n-1) + 3; generating function = 1/(exp(x)-1).

Give up to 3 **references**:

M. Jones, On the enumeration of graphs, American Mathematical Monthly, Vol. 100 (1993), pp. 1-25.

M. Jones, Further remarks on the enumeration of graphs, preprint, 2001.

Give up to 3 **links**. Please use the format shown in the examples, or the link won't be visible in the database. If possible include journal references for online articles.

J. H. Smith, Perfect Numbers.

A. R. Calderbank, E. M. Rains, P. W. Shor and N. J. A. Sloane, Quantum error correction via codes over GF(4), IEEE Trans. Inform. Theory, 44 (1998), 1369-1387.

J. C. P. Muller and W. T. Gardner, On Cacti Spine Symmetry Groups, J. Math. Horticult. 17 (1995), 862-877.

Give an **example**: E.g. "a(7)=2 because we can write 7=2+5 or 2+2+3."

Comments:

Program to generate the sequence: Maple

Name: Bell or exponential numbers: ways of placing n labeled balls into n indistinguishable boxes.
Comments: On first day, each gossip has his own tidbit. On each successive day, disjoint pairs of
gossips may share tidbits (over the phone). After a(n) days, all gossips have all
tidbits.

Extension: Extended by David Wilson (wilson(AT)ctron.com), Mar 10, 1999.
```

Explanation of the Different Lines

ID Number

- The A-number (for example A000108) is the absolute catalogue number of the sequence. It consists of A followed by 6 digits.
- Some sequences also have a 4-digit M-number, such as M1459, which is the number they carried in **"The Encyclopedia of Integer Sequences"** by N.J.A. Sloane and S. Plouffe, Academic Press, San Diego, CA, 1995.
- Some older sequences also have a 4-digit N-number, such as N0577, which is the number they carried in the "Handbook of Integer Sequences", by N. J. A. Sloane, Academic Press, NY, 1973.

Sequence

- These lines give the beginning of the sequence.
  - For example: 0,1,1,2,3,5,8,13,21,34,55,89,144,...
- Ideally the entry gives enough terms to fill about three lines on the screen.
- If the sequence contains negative numbers then the Sequence lines give the **absolute values** of the terms.
- The terms must be integers.
- If the terms are fractions, then the numerators and denominators appear as separate sequences, labeled with the Keyword "frac", and with links connecting the two sequences.
- Only sequences that are well-defined and of general interest are included.

Signed

- These lines give the beginning of the sequence, in the case that some of the terms are negative.
- The Ramanujan numbers, sequence A000594, are a famous example.
- In such cases the Sequence lines give the beginning of the sequence as unsigned numbers. These numbers match one-to-one with the numbers in the "Signed" lines.

Name

- The "Name" line gives a brief description or definition of the sequence.
  - For example: The even numbers.
- In the description, a(n) usually denotes the n-th term of the sequence, and n is a typical subscript.

- For example: a(n) = a(n-1) + a(n-3).
- In some cases however n denotes a typical term in the sequence.
  - For example: n and n+1 have the same number of divisors.

Comments

- Additional remarks about the sequence that do not fit into any of the other lines (additional situations where the sequence occurs, for instance).

References

- References where information about the sequence can be found.
- Whenever possible the reference gives full bibliographical information:
  - For an article in a journal: author(s), title of article, name of journal, volume, issue number if relevant, year, starting and ending page numbers, etc.
  - For a book: author(s), title, publisher, place, year, edition, page numbers where sequence appears, etc.
  - For an article in a book: author(s), title of article, page numbers, editors' names, title of book, publisher, place, year, etc.

Links

- Links related to this sequence
- Preferred format:

  J. B. Smith, < a href = " http : // www.this.that.com/etc/etc.html ">Title< /a >

  - spaces have been inserted to make it visible, but you should not insert any spaces of course.

  In other words, the format is

  Author, Title

- Web page addresses can change very quickly, so if you find a link that is broken, please inform njas@research.att.com.

Formula

- These lines give formulae, recurrences, generating functions, etc. for the sequence.
- a(n) usually denotes the n-th term of the sequence, and n is a typical subscript.
- Note that the Offset line gives the value of n corresponding to the first term shown.
  - An example of an explicit formula: a(n) = n^2 + n + 1.
  - An example of a recurrence: a(n+1) = 2 * a(n) - (-1)^n * 3.
- The ordinary generating function (G.f.) for a sequence a(0), a(1), a(2), ... is the formal power series

```
A(x) = a(0) + a(1)*x + a(2)*x^2 + a(3)*x^3 + ...
```

- An example of an ordinary generating function: G.f.: A(x) = 1/(1-x)^4.
- Usually one can think of an ordinary generating function as a Taylor series, and extract the nth coefficient by differentiating A(x) n times, setting x = 0, and dividing by n!. Computer algebra languages such as Maple make this easy - one simply says (for example) series(A,x,100).

- The exponential generating function (E.g.f.) for a sequence a(0), a(1), a(2), ... is the formal power series

$$A(x) = \frac{a(0)}{1} + \frac{a(1)x}{1} + \frac{a(2)x^2}{2} + \frac{a(3)x^3}{6} + \frac{a(4)x^4}{24} + \ldots$$

where the numbers in the denominators are the factorial numbers n! = 1*2*3*4*...*n, Sequence A000142.

- An example of an exponential generating function: E.g.f.: A(x) = exp(exp(x)-1).

Example

- These lines give expanded information or examples to illustrate the initial terms of the sequence.
  - For instance: 4=2^2, so a(4)=1; 5=1^2+2^2=2^2+1^2, so a(5)=2.
- If the sequence is formed from the coefficients of a power series, this line can be used to show the beginning of the series.
  - For instance: 1+3600*q^3+101250*q^4+...
- If the sequence is formed from the decimal expansion or continued fraction expansion of a real number, this line may show the actual decimal expansion.
  - For instance: 3.14159265358979323846264338327950288 4...
- If the sequence is formed by reading the rows of an array, this line may show the beginning of the array (see the Keywords "tabl" and "tabf" below.)
  - For instance: {1}; {1,1}; {1,2,1}; {1,3,3,1}; {1,4,6,4,1}; ...

Maple

- These lines give Maple code to produce the sequence. Examples:
  - f:=i->if isprime(i) then 1 else 0; fi; [seq(f(i),i=0..100)];
  - for i from 1 to 100 do if isprime(i) then print(nops(factorset(i-1))); fi; od;

Math'ca

- These lines give Mathematica code to produce the sequence. For example:
  - Table[If[n==1,1,LCM@@Map[(#1[[1]]-1)*#1[[1]]^(#1[[2]]-1)&, FactorInteger[n]]], {n,1,70}]

Program

- These lines give a program in some other language that will produce the sequence. Examples:
  - (PARI) v=[];for(n=0,60,if(isprime(n^2+n+41),v=concat(v,n),));v
  - (MAGMA) R := ReedMullerCode(2,7); print(WeightEnumerator(R));

See also

- These lines gives cross-references to related sequences. Examples:
  - Cf. A006546, A007104, A007203.
  - a(n) = A025582(n)^2+1.

- **Sequence in context.** This line show the three sequences immediately before and after the sequence in the lexicographic listing. Example:
  - Sequence in context: A036656 A000055 A006787 this_sequence A036648 A047750 A072187

- **Adjacent sequences.** This line show the three sequences whose A-numbers are immediately before and after the A-number of the sequence. Example:
  - Adjacent sequences: A000989 A000990 A000991 this_sequence A000993 A000994 A000995

Keywords

These lines give keywords describing the sequence. At present the following keywords are in use.

- **base**: Sequence is dependent on base used
- **bref**: Sequence is too short to do any analysis with
- **cofr**: A continued fraction expansion of a number
- **cons**: A decimal expansion of a number
- **core**: An important sequence
- **dead**: An erroneous or duplicated sequence (the table contains a number of incorrect sequences that have appeared in the literature, with pointers to the correct versions)
- **dumb**: An unimportant sequence
- **dupe**: Duplicate of another sequence
- **easy**: It is easy to produce terms of this sequence
- **eigen**: An **eigensequence**: a fixed sequence for some transformation - see the files transforms and transforms (2) for further information.
- **fini**: A finite sequence
- **frac**: Numerators or denominators of sequence of rational numbers
- **full**: The full sequence is given (implies that the sequence is finite)
- **hard**: Next term is not known, and may be hard to find. Would someone please extend this sequence?
- **more**: More terms are needed and should not be difficult to find. Would someone please extend this sequence?
- **mult**: Multiplicative: a(mn)=a(m)a(n) if g.c.d.(m,n)=1
- **new**: New (added within last two weeks, roughly)
- **nice**: An exceptionally nice sequence
- **nonn**: A sequence of nonnegative numbers (more precisely, all the displayed terms are nonnegative; it is not excluded that later terms in the sequence become negative)
- **obsc**: Obscure, better description needed
- **sign**: Sequence contains negative numbers
- **tabf**: An irregular (or funny-shaped) array of numbers made into a sequence by reading it row by row
- **tabl**: A regular array of numbers, such as Pascal's triangle, made into a sequence by reading it row by row
- **uned**: Not edited. I normally edit all incoming sequences to check that:
  - the sequence is worth including
  - the definition is sensible
  - the sequence is not already in the database
  - the English is correct

- the different parts of the entry all have the correct prefixes: cross-references are in %Y lines, formulae in %F lines, etc.
- any %H lines are correctly formatted (this is easy to get wrong)
- etc.

The keyword "uned" indicates that this sequence was not edited, usually because of time pressure. Perhaps someone could edit this sequence and email me the result.

- **unkn**: Little is known; an unsolved problem; anyone who can find a formula or recurrence is urged to send me email
- **walk**: Counts walks (or self-avoiding paths)
- **word**: Depends on words for the sequence in some language

Offset

- This line usually gives the subscript of the first term in the sequence.
  - For example: the Fibonacci numbers F(0), F(1), F(2), ... begin 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89,... and the subscript of the initial term is 0, so the "Offset" line is **0**
- If the sequence gives the decimal expansion of a constant, the offset is the number of digits before the decimal point.
  - For example, the speed of light is 299792458 (m/sec), giving the sequence 2,9,9,7,9,2,4,5,8, with offset **9** .

Author

- These lines give the name and (usually) the email address of the person who contributed the sequence. For example: Clark Kimberling (ck6(AT)evansville.edu)
- Some frequent contributors, including Simon Plouffe (sp), David Wilson (dww), Robert G. Wilson V (rgwv), and myself (njas), have been indicated just by their initials.

Extension

- **E** stands for **Extensions**, **Errors** or **Edited**. These lines contain information about sequences that have been significantly extended, errors that have been corrected, or entries in the database that have been edited by someone.
- The errors might be in an earlier version of the entry in the database or in the published literature.
- Examples:
  - Corrected and extended by Henry Bottomley (se16(AT)btinternet.com), Jan 01 2002
  - The sixth term is incorrect in the book by Smith and Jones.
  - Edited by Dean Hickerson (dean(AT)math.ucdavis.edu), Jan 02 2002

Arrays

- The database also contains a number of sequences based on triangular or square arrays, such as **Pascal's Triangle**:

1

1 1

```
                    1       2       1
                1       3       3       1
            1       4       6       4       1
        1       5       10      10      5       1
    ...     ...     ...     ...     ...     ...     ...
```

When read by rows this produces the sequence 1, 1, 1, 1, 2, 1, 1, 3, 3, 1, 1, 4, 6, 4, 1, ..., Sequence A007318.

- Square arrays are usually read by anti-diagonals. For example, the **Nim-addition table**:

0	1	2	3	4	5
1	0	3	2	5	4
2	3	0	1	6	7
3	2	1	0	7	6
4	5	6	7	0	1
.	.	.	.	.	.

when read by anti-diagonals produces the sequence 0, 1, 1, 2, 0, 2, 3, 3, 3, 3, 4, 2, 0, 2, 4, ..., Sequence A003987.

- The typical term in these arrays is usually denoted by a(n,k) (sometimes T(n,k)) in the Formula lines.
- The Example lines for these sequences usually show the beginning of the two-dimensional array.
- These sequences are usually indicated by the Keyword **tabl**.
- Some ordinary (one-dimensional) sequences also have the keyword **tabl**, indicating that they can also be regarded as arrays.
- The Keyword **tabf** indicates a sequence formed by reading a "funny-shaped" array. More precisely, this a sequence where the array cannot be recovered simply by breaking up the sequence into chunks of successive lengths 1, 2, 3, 4, 5, ... Typically one has to use chunks of lengths 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, ... or 1, 3, 5, 7, 9, 11, 13, ... for "tabf" sequences. See A028297 and A027113 for examples.

Wolfdieter Lang has a very nice program that will format both "tabl" and "tabf" sequences. It is not finished yet but there is a preliminary version at http://www-itp.physik.uni-karlsruhe.de/~wl/Anumbertest.html

---

Transformations of Integer Sequences

A subpage of the The On-Line Encyclopedia of Integer Sequences which makes extensive use of these transformations.

Keywords: AND-convolution, binomial, bisect, boustrophedon, complement, convolution, decimate, differences, Euler, exponential, inverse, Lambert, lcm-convolution, logarithmic, Moebius (or Mobius), OR-convolution, partial products, partial sums, partition, revert (or reversion), sort, trisect, XOR-convolution, weigh, etc., transforms; Maple.

This file is basically a pointer to a **plain text file** which contains Maple procedures for performing a large number of useful transformations on sequences and numbers.

See also the **sequel** to this page written by Christian G. Bower.

Puzzle Sequences From

The On-Line Encyclopedia of Integer Sequences

Can you guess the rules for generating these sequences?
Note that I believe in giving at least ten terms as a hint.

- This one was in the New York Times a while back:
  2, 3, 3, 5, 10, 13, 39, 43, 172, 177, ... Give up?

- 0, 0, 0, 0, 4, 9, 5, 1, 1, 0, 55, ...
  Hint: write out
  one, two, three, four, five, six, seven, eight, nine, ten, eleven, ...
  and think like a Roman! Give up?

- From **Chess Life**, said to be a sequence that the world chess champion did not guess (except I bet he was not given 10 terms):
  7, 9, 40, 74, 1526, 5436, 2323240, 29548570, 5397414549030, 873117986721660, ...
  Give up?

- Everyone knows about the even numbers, sequence A005843.
  Less well-known are the **eban** numbers (the name is a strong hint!):
  2, 4, 6, 30, 32, 34, 36, 40, 42, 44, 46, ... Give up?

- Somewhat in the same spirit are the **emirps**:
  13, 17, 31, 37, 71, 73, 79, 97, 107, 113, ... Give up?

- Elegant, classic:
  1, 2, 2, 3, 3, 4, 4, 4, 5, 5, 5, 6, 6, 6, 6, 7, 7, 7, 7, 8, 8, 8, 8, 9, 9, 9, 9, ... Give up?

- What about this one?
  1, 3, 7, 12, 18, 26, 35, 45, 56, 69, 83, ... Give up?

  Hmmm! Still thinking? I've seen nine-year-olds guess it quicker than that.

- This one is easy for smart seventeen-year-olds, or if you've seen it before, otherwise not!
  2, 12, 1112, 3112, 132112, 1113122112, 311311222112, 13211321322112,
  1113122113121113222112, 31131122211311123113322112, ... Give up?

  John Conway's astonishing analysis of the asymptotic properties of the above sequence is well worth reading - see the reference given.

- Very easy:
  1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25... Give up?

- Also not so hard if approached in the right way:
  1, 2, 6, 20, 70, 252, 924, 3432, 12870, 48620, ... Give up?

The "RATS" sequence!

1, 2, 4, 8, 16, 77, 145, 668, 1345, 6677, 13444, 55778, ... Give up?

Hot Sequences From

The On-Line Encyclopedia of Integer Sequences

A selection of the best and the worst of the sequences received recently. For more information about these sequences, look them up in **The On-Line Encyclopedia of Integer Sequences**.

1. **Lionel Levine's sequence:**

   1, 2, 2, 3, 4, 7, 14, 42, 213, 2837, 175450, 139759600, 6837625106787, 26643714491664860784, 508009471379488821444261986503540, ...

   It is generated by this array, the final term in each row (colored red) forming the sequence:

```
 1 1
 1 2
 1 1 2
 1 1 2 3
 1 1 1 2 2 3 4
 1 1 1 1 2 2 2 3 3 4 4 5 6 7
 1 1 1 1 1 1 1 2 2 2 2 2 2 3 3 3 3 3 4 4 4 4 5 5 5 5 6 6 6 7 7 7
8 8 9 9 10 10 11 12 13 14
 ...
```

   where we start with the first row {1 1} and produce the rest of the array recursively as follows: Suppose line n is {a_1, ..., a_k}; then line n+1 contains a_k 1's, a_{k-1} 2's, etc.

   So the fifth line contains three 1's, two 2's, one 3 and one 4.

   The sequence is 1,2,2,3,4,7,14,42,213,2837,175450,...,
   where the nth term a(n) is
   the sum of the elements in row n-2

=the number of elements in row n-1
=the last element in row n
=the number of 1's in row n+1
=...

If the n-th row is r_{n,i} then

```
  Sum        (a(n+1) - i + 1)*r_{n,i} ) = a(n+3)
i=1..f(n+1)
```

Let {a( )} be the sequence; s(i,j) = jth partial sum of the ith row, L(i) is the length of that row and S(i) = its sum. Then
L(i+1) = a(i+2) = S(i) = s(i,a(i+1));
L(i+2) = SUM(s(i,j));
L(i+3) = SUM(s(i,j)*(1+s(i,j))/2) (Allan Wilks).

Eric Rains and Bjorn Poonen have shown (6/97) that the log of the nth term is asymptotic to constant times phi^n, where phi = golden number. This follows from the inequalities S(n) <= a(n) L(n) and S(n+1) >= ([L(n+1)/a(n)]+1) choose 2)*a(n).

The nth term is approximately exp(a*phi^n)/I, where phi = golden number, a = .05427 (last digit perhaps 6 or 8), I = .277 (last digit perhaps 6 or 8) (Colin Mallows).

It would be nice to have a few more terms!

2. **4, 4, 341, 6, 4, 4, 6, 6, 4, 4, 6, 10, 4, 4, 14, 6, 4, 4, 6, 6, 4, 4, 6, 22, 4, 4, 9, 6, ...**

The Primary Pretenders: the least composite c such that n sup c == n (mod c).
It is remarkable that this sequence is periodic with period
195685843334600725872453400377362789820172138293376043367343629473864777739548319609797185299925992132923650684236043930 0
See **further discussion** or the full paper: **The Primary Pretenders**, by J. H. Conway, R. K. Guy, W. A. Schneeberger and N. J. A. Sloane (available in pdf or postscript form).

3. **1, 2, 4, 9, 24, 77, 294, 1309, 6664, 38177, 243034, 1701909, 13001604, ...**

Fill in a triangle, like Pascal's triangle, beginning each row with a 1, and **filling in rows alternately right to left and left to right**. Thus:

```
          1
1   ->    2
```

```
   4  <- 3   <-  1
1  -> 5  ->  8   ->  9
   . . . . . . . . . . . .
```

See **A New Operation on Sequences: The Boustrophedon Transform**, J. Millar, N. J. A. Sloane and N. E. Young (available in pdf or postscript form).

4. **0, 1, -3, -1, 1, -4, -1, 0, -7, -1, 0, -226, -1, 0, 7, -1, 0, 3, -2, 0, 2, -2, 0, 1, -3, -1, 1, ...**

   Integer part of tan(n).

5. **2, 3, 2, 3, 2, 4, 2, 3, 2, 3, 2, 5, 2, 3, 2, 3, 2, 4, 2, 3, 2, 3, 2, 5, 2, 3, 2, 3, 2, 4, 2, 3, 2, 3, 2, 5, ...**

   Least non-divisor of n. From Jeffrey Shallit, shallit@graceland.uwaterloo.ca.

6. **0, 2, 3, 6, 7, 1, 9, 4, 5, 8, 22, 23, 26, 27, 21, 29, 24, 25, 28, 20, 12, 32, 33, 36, 37, 31, ...**

   1-digit numbers in reversed alphabetical order, then the 2-digits numbers, etc.

7. **1, 2, 3, 5, 9, 12, 21, 22, 23, 25, 29, 31, 32, 33, 35, 39, 41, 42, 43, 45, 49, 51, 52, ...**

   Numbers ending with a vowel.

8. **5, 5, 5, 3, 4, 4, 4, 2, 5, 5, 5, 3, 6, 6, 6, 5, 10, 10, 10, 8, ...**

Classic Sequences In

The On-Line Encyclopedia of Integer Sequences

The Wythoff Array and The Para-Fibonacci Sequence

The Wythoff array A035513 is shown below, to the right of the broken line. It has many wonderful properties, some of which are listed after the table. It is also related to a large number of sequences in the On-Line Encyclopedia.

```
 0    1  |   1    2    3    5    8   13   21   34   55   89  144

```

Some properties of the Wythoff array.

(For sources see the "References" below.)

- **Construction (1)**: the two columns to the left of the broken line consist respectively of the nonnegative integers n, and the **lower Wythoff sequence** A000201, whose nth term is [(n+1)tau], where tau=(1+sqrt(5))/2. The rows are then filled in by the Fibonacci rule that each term is the

sum of the two previous terms. The entry n in the first column is the **index** of that row.

- Two definitions: The **Zeckendorf expansion** of n is obtained by repeatedly subtracting the largest Fibonacci number you can until nothing remains; for example 100 = 89 + 8 + 3 (see A035514- A035517).
  The **Fibonacci successor** to (or **left shift** of) n, Sn, say, is found by replacing each F_i in the Zeckendorf expansion by F_{i+1}; for example the successor to 100 is S100 = 144 + 13 + 5 = 162. See A022342.

- **Construction (2)**: the two columns to the left of the broken line read n, 1+Sn; then after the broken line the sequence is

  m Sm SSm SSSm SSSSm ... ,

  where m = n + 1 + Sn.

- **Construction (3)**: Let {S1, S2, S3, S4, ...} = {2,3,5,7,8,10,11,...} be the sequence of Fibonacci successors A022342. The first column of the array consists of the numbers not in that sequence: 1,4,6,9,12,... (A007067). The rest of each row is filled in by repeatedly applying S.

- **Construction (4)**: The entry in row n and column k is

  $$[(n+1) \text{ tau }] F_{k+2} + n F_{k+1} ,$$

  where $\{F_0, F_1, F_2, F_3, ...\} = \{0,1,1,2,3,5,...\}$ are the Fibonacci numbers A000045.

- 1. The first row of the Wythoff array consists of the Fibonacci sequence 1,2,3,5,8,... A000045
  2. Every row satisfies the Fibonacci recurrence;
  3. The leading term in each row is the smallest number not found in any earlier row;
  4. Every positive integer appears exactly once in the array;
  5. The terms in any row or column are monotonically increasing;
  6. Every positive Fibonacci-type sequence (i.e. satisfying a(n)=a(n-1)+a(n-2) and eventually positive) appears as some row of the array;
  7. The terms in any two rows alternate.

  There are infinitely many arrays with properties 1-7, see [Kim95a].

- Another especially interesting array with properties 1-7 is the **Stolarsky array**: A035506,

```
 1    2    3     5     8    13    21    34    55    89
```

```
 4   6  10   16   26   42   68  110  178  288
 7  11  18   29   47   76  123  199  322  521
 9  15  24   39   63  102  165  267  432  699
12  19  31   50   81  131  212  343  555  898
14  23  37   60   97  157  254  411  665 1076
17  28  45   73  118  191  309  500  809 1309
20  32  52   84  136  220  356  576  932 1508
22  36  58   94  152  246  398  644 1042 1686
25  40  65  105  170  275  445  720 1165 1885
```

- The kth column of the Wythoff array consists of the numbers whose Zeckendorf expansion ends with F_k.

- The nth term of the vertical **para-Fibonacci sequence**

  0, 0, 0, 1, 0, 2, 1, 0, 3, 2, 1, 4, 0, 5, 3, 2, 6, 1, 7, 4, 0, 8, 5, ...

  (A019586 or, for the original form, A003603) gives the index (or parameter) of the row of the Wythoff array that contains n.

  This sequence also has some nice properties.
  A. If you delete the first occurrence of each number, the sequence is unchanged. Thus if we delete the red numbers from

  0, 0, 0, 1, 0, 2, 1, 0, 3, 2, 1, 4, 0, 5, 3, 2, 6, 1, 7, 4, 0, 8, 5, ...

  we get

  0, 0, 0, 1, 0, 2, 1, 0, 3, 2, 1, 4, 0, 5, 3, 2, 6, 1, 7, 4, 0, 8, 5, ...

  again!

  B. Between any two consecutive 0's we see a permutation of the first few positive integers, and these nest, so the sequence can be rewritten as:

```
0
0
0                   1
0           2       1
0       3   2       1       4
0   5   3   2     6 1     7 4
0 8 5 3 9 2 10 6 1 11 7 4 12
```

- The nth term of the horizontal **para-Fibonacci sequence**

  1, 2, 3, 1, 4, 1, 2, 5, 1, 2, 3, 1, 6, 1, 2, 3, 1, 4, 1, 2, 7, 1, 2, ...

  (A035612) gives the index (or parameter) of the column of the Wythoff array that contains n. This sequence also has a very nice property (see the entry).

Associated Sequences

Successive columns of the Wythoff array A035513 give sequences A000201 (just before the broken line);
A007065, A035336, A035337, A035338, A035339, A035340.
Successive rows give the Fibonacci numbers A000045, the Lucas numbers A000204, the doubled

Fibonacci numbers A013588, the trebled Fibonacci numbers A022086, A022087, A000285, A022095, etc.
The main diagonal is A020941.

Losanitsch's Triangle

An analogue of Pascal's triangle that deserves to be better known.

								1														
							1		1													
						1		1		1												
					1		2		2		1											
				1		2		4		2		1										
			1		3		6		6		3		1									
		1		3		9		10		9		3		1								
	1		4		12		19		19		12		4		1							
1		4		16		28		38		28		16		4		1						
1		5		20		44		66		66		44		20		5		q				

The rule for producing these numbers is essentially the same as for Pascal's triangle: each term is the sum of the two numbers immediately above it, except that (numbering the rows by n=0,1,2,... and the entries in each row by k=0,1,2,...) if n is even and k is odd - the red entries! - we subtract C(n/2-1,(k-1)/2).

Formally,

a(n,k)=a(n - 1,k - 1)+a(n - 1,k) - C(n/2 - 1,(k - 1)/2), where the last term is present only if n even, k odd.

Reference: S. M. Losanitsch, Die Isomerie-Arten ... Paraffin-Reihe, **Chem. Ber. 30** (1897), 1917-1926.

The sequence formed by reading the triangle by rows is A034851, and the successive diagonals are A000012, A004526, A002620, A005993, A005994, A005995, A018210, A018211, A018212, A018213, A018214. The central columns yield A034872, A032123, A005654. The row sums form A005418. The difference between Pascal's triangle and the Losanitsch triangle gives the triangle shown in A034852.

The even-numbered diagonals are the partial sums of the previous diagonals. A generating function for the (2m)-th diagonal is

$$\frac{\text{Sum } C(m+1, 2i)\, x^{2i},\ i = 0,1,2,\ldots}{\{(1-x)(1-x^2)\}^{m+1}}$$

and that for the (2m+1)st diagonal is obtained by dividing that by 1-x.

For example, the 5th diagonal 1,3,12,28,66,126,... has generating function

$$\frac{(1+3x^2)}{\{(1-x)(1-x^2)\}^3}.$$

Posets.

How many partially ordered sets are there with n elements? (Sequence A001035.)
If the points are distinguishable, i.e. labeled, then for n = 1, 2, 3, ... points the numbers are:

1, 3, 19, 219, 4231, 130023, 6129859, ...

At present these numbers are known up through 13 points. Click to see the full entry

Some related sequences are:

- A000112 (unlabeled posets)
- A000798 (labeled topologies)
- A001930 (unlabeled topologies)

Hadamard's maximal determinant problem:

What is the largest determinant of any n x n matrix with entries that are 0 and 1 ?
Here is the sequence (for n = 1, 2, ...):

1, 1, 2, 3, 5, 9, 32, 56, 144, 320, 1458, 3645, 9477

The next term is not known - won't someone please find it?

Click to see the full entry

[Quite a lot is known about the above problem. See for example the survey article by J. Brenner in the Amer. Math. Monthly, June/July 1972, p. 626, and further comments in the issues of Dec. 1973, Dec. 1975 and Dec. 1977.
If n+1 is divisible by 4, and a Hadamard matrix of order n exists, then f(n) = (n+1)^{(n+1)/2}/2^n.
There are 4 equivalent versions of the problem: find the max determinant of a matrix with entries that are:
o 0 or 1, or
o in the range 0 <= x <= 1, or
o -1 or 1, or
o in the range -1 <= x <= 1.]

Bell numbers:

Expand $\exp(e^x - 1)$ in powers of x, SUM $B_n x^n / n!$. The coefficients B_n are the Bell numbers:

1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, 115975, 678570, 4213597, 27644437, ...

Click to see the full entry

Motzkin numbers:

1, 1, 2, 4, 9, 21, 51, 127, 323, 835, 2188, 5798, 15511, 41835, ...

Click to see the full entry

Like the Catalan numbers, the Motzkin numbers have many interpretations. For example:

- the number of ways to join n points on a circle by nonintersecting chords
- Paths from (0,0) to (n,0) that do not go below the horizontal axis and are made up of steps (1,1) (i. e. NE), (1,-1) (i. e. SE) and (1,0) (i.e. E).
- a(n) = number of (s(0), s(1), ..., s(n)) such that s(i) is a nonnegative integer and |s(i) - s(i-1)| <= 1 for i = 1,2,...,n, s(0) = 0 = s(n).

Formulae:

- G.f.: (1 - x - (1-2*x-3*x^2)^(1/2)) / (2*x^2).
- G.f. satisfies A(x) = 1 + xA(x) + x^2 A(x)^2.
- Recurrence: a(n) = (-1/2) SUM (-3)^a C(1/2,a) C(1/2, b); a+b=n+2, a>=0, b>=0.
- In Maple: seriestolist(series((1-x-(1-2*x-3*x^2)^(1/2))/(2*x^2),x,40));
- In Mathematica: a[0]=1;a[n_Integer]:=a[n]=a[n-1]+Sum[a[k]*a[n-2-k],{k,0,n-2}]; Array[a[#]&, 30]

Perfect numbers:

Numbers that are equal to the sum of every (smaller) number that divides them.
For example 6 is perfect because it is divisible by 1, 2 and 3, and 1 + 2 + 3 = 6.
The sequence of perfect numbers begins:

6, 28, 496, 8128, 33550336, 8589869056, 137438691328,

2305843008139952128, 2658455991569831744654692615953842176, ...

Only some thirty or so perfect numbers are known. These are some of the largest numbers that have ever been computed. Click to see the full entry

Aronson's sequence:

1, 4, 11, 16, 24, 29, 33, 35, 39, 45, 47, 51, 56, 58, 62, 64, ...
whose definition is:

t is the first, fourth, eleventh, ... letter of this sentence

Abstract

We define a multiplicative arithmetic function D by assigning $D(p^a) = ap^{a-1}$, when p is a prime and a is a positive integer, and, for $n \geq 1$, we set $D^0(n) = n$ and $D^k(n) = D(D^{k-1}(n))$ when $k \geq 1$. We term $\{D^k(n)\}_{k=0}^{\infty}$ the derived sequence of n. We show that all derived sequences of $n < 1.5 \cdot 10^{10}$ are bounded, and that the density of those $n \in \mathbb{N}$ with bounded derived sequences exceeds 0.996, but we conjecture nonetheless the existence of unbounded sequences. Known bounded derived sequences end (effectively) in cycles of lengths only 1 to 6, and 8, yet the existence of cycles of arbitrary length is conjectured. We prove the existence of derived sequences of arbitrarily many terms without a cycle.

1 Introduction

Define a multiplicative arithmetic function D by assigning

$$D(p^a) = ap^{a-1}, \tag{1}$$

when p is a prime and a is a positive integer. The multiplicativity implies $D(1) = 1$ and, for example, $D(p^a q^b) = abp^{a-1}q^{b-1}$, where q^b is another prime power, $q \neq p$. It is only

the shape of the definition (1) that encourages us to use freely terms from calculus. (Our derivatives have no relationship to an earlier use of the term, in Apostol [1], for example.) Writing $D^0(n) = n$ and $D^k(n) = D(D^{k-1}(n))$ for $k \geq 1$ and any positive integer n, we call $\{D^k(n)\}_{k=0}^{\infty}$, or $\{n, D(n), D^2(n), D^3(n), \dots\}$, the derived sequence of n, and denote this by $\mathcal{D}(n)$. We refer to $D^k(n)$ for $k \geq 1$ as the kth derivative of n and we refer to $D^j(n)$ for $0 \leq j < k$ as integrals of $D^k(n)$.

If $n = \prod_{i=1}^{w} p_i^{a_i}$ is the prime decomposition of n then the definition of $D(n)$ may be given differently as

$$D(n) = \frac{n}{C(n)}\,\tau\left(\frac{n}{C(n)}\right),$$

where $\tau(n) = \prod_{i=1}^{w}(a_i + 1)$ is the number of divisors of n and $C(n) = \prod_{i=1}^{w} p_i$ is the core of n.

Our intention is to initiate a study of the ultimate behaviour of derived sequences. Different forms of ultimate behaviour are indicated in the following examples:

$$\mathcal{D}(5^2 17 \cdot 37) = \{5^2 17 \cdot 37, 2 \cdot 5, \underline{1}, \dots\}, \tag{2}$$
$$\mathcal{D}(2^{25}) = \{2^{25}, 2^{24}5^2, 2^{27}3 \cdot 5, 2^{26}3^3, \underline{2^{26}3^3 13}, \dots\}, \tag{3}$$
$$\mathcal{D}(13^{16}) = \{13^{16}, 2^4 13^{15}, 2^5 3 \cdot 5 \cdot 13^{14}, 2^5 5 \cdot 7 \cdot 13^{13}, \underline{2^4 5 \cdot 13^{13}}, \underline{2^5 13^{13}}, \dots\}, \tag{4}$$
$$\mathcal{D}(2^{32}) = \{2^{32}, 2^{36}, \underline{2^{37}3^2}, \underline{2^{37}3 \cdot 37}, \underline{2^{36}37}, \dots\}, \tag{5}$$
$$\mathcal{D}(3^8) = \{3^8, \underline{2^3 3^7}, \underline{2^2 3^7 \cdot 7}, \underline{2^2 3^6 \cdot 7}, \underline{2^3 3^6}, \dots\}. \tag{6}$$

The underlined terms in each case form cycles. Precisely: if

$$\mathcal{D}(n) = \{\dots, D^j(n), D^{j+1}(n), \dots, D^{j+k-1}(n), D^{j+k}(n), \dots\}$$

and $D^{j+k}(n) = D^j(n)$, where $j \geq 0$ and $k \geq 1$ is the smallest integer with this property, then $D^j(n), D^{j+1}(n), \dots, D^{j+k-1}(n)$ is a derived k-cycle, which, if we need to, we describe as being arrived at in $j + k$ iterations of D. For example, in (3), $D(2^{26}3^3 13) = 2^{26}3^3 13$, and, in (6), $D(2^3 3^6) = 2^3 3^7$. We have 1-cycles in (2) and (3), and 2-, 3- and 4-cycles in (4), (5) and (6), respectively. The 3-cycle in (5) is arrived at in four iterations of D. We will refer to the element of a 1-cycle as a fixed point of D.

It is not known whether the ultimate behaviour of $\mathcal{D}(n)$ is a cycle for all n, or whether, for some n, $D^k(n)$ increases without bound as k increases. We will show, however, that cycles result for more than 99.5% of values of n. Many iterations of D may be required before a cycle is reached, if that is to be the case: for example, $\mathcal{D}(5^{63})$ arrives in 531 iterations at the fixed point $2^{1403}3^{329}5^{106}7^{15}23 \cdot 47 \cdot 53 \cdot 61$. Our most impressive example is $\mathcal{D}(17^{35}19^{39})$, which, in 443507 iterations of D, arrives at the fixed point

$$2^{4318267}3^{1370053}5^{525835}7^{159649}11^{33429}13^{20597}17^{1037}19^{1349}23^{299}31^{31}$$
$$\cdot\, 43 \cdot 61 \cdot 71^2 479 \cdot 1013 \cdot 22807 \cdot 105167 \cdot 1370053 \cdot 4318267.$$

Other instances of sequences of iterated arithmetic functions are given by Guy [3]. Iteration of the function $\sigma(n) - n$, for example, where σ is the sum-of-divisors function, has been studied extensively. The situation is similar: there is an eventual iterate equal to 1, or

there is eventually a cycle, or the ultimate behaviour is unknown. Iteration of the function σ itself was studied in Cohen and te Riele [2].

In the following, p, q, r and t, with and without subscripts, denote prime numbers, and s, with and without subscripts, denotes a squarefree number. We include 1 as a squarefree number. Other letters denote positive integers, unless specified otherwise.

2 General results

We are able to give a number of results of a general nature.

First, it is easy to see that n is a fixed point of D if and only if either $n = 1$ or $n = \prod_{i=1}^{w} p_i^{a_i}$, where $\prod_{i=1}^{w} p_i = \prod_{i=1}^{w} a_i$. More generally, we have Proposition 1, below. For simplicity of notation, we will write $n = \prod p_0^{a_0}$ and $D(n) = \prod p_1^{a_1}$ as shorthand for $n = \prod_{i=1}^{w_0} p_{i0}^{a_{i0}}$ and $D(n) = \prod_{i=1}^{w_1} p_{i1}^{a_{i1}}$, and so on.

Proposition 1 *Suppose $n > 1$ and write $n = \prod p_0^{a_0}$, $D(n) = \prod p_1^{a_1}$, $\ldots$, $D^{k-1}(n) = \prod p_{k-1}^{a_{k-1}}$. We have $D^k(n) = n$ if and only if $\prod p_0 \prod p_1 \cdots \prod p_{k-1} = \prod a_0 \prod a_1 \cdots \prod a_{k-1}$.*

Proof. Note that

$$\begin{aligned}
n &= \prod p_0^{a_0}, \\
D(n) &= \prod p_1^{a_1}, \quad \text{so} \quad \prod p_1^{a_1} = \prod a_0 p_0^{a_0-1}, \\
D^2(n) &= \prod p_2^{a_2}, \quad \text{so} \quad \prod p_2^{a_2} = \prod a_1 p_1^{a_1-1}, \\
&\vdots \\
D^{k-1}(n) &= \prod p_{k-1}^{a_{k-1}}, \quad \text{so} \quad \prod p_{k-1}^{a_{k-1}} = \prod a_{k-2} p_{k-2}^{a_{k-2}-1}.
\end{aligned}$$

If, further, $D^k(n) = n$ then $\prod p_0^{a_0} = \prod a_{k-1} p_{k-1}^{a_{k-1}-1}$, and we have

$$\begin{aligned}
\prod p_0 \prod p_1 \cdots \prod p_{k-1} &= \frac{\prod p_1^{a_1}}{\prod p_0^{a_0-1}} \frac{\prod p_2^{a_2}}{\prod p_1^{a_1-1}} \cdots \frac{\prod p_{k-1}^{a_{k-1}}}{\prod p_{k-2}^{a_{k-2}-1}} \frac{\prod p_0^{a_0}}{\prod p_{k-1}^{a_{k-1}-1}} \\
&= \prod a_0 \prod a_1 \cdots \prod a_{k-1}.
\end{aligned}$$

The converse is also clear. □

It does not seem to be easy to use this result to determine cycles, but we can at least identify those numbers which have a derivative equal to the fixed point 1 of D:

Proposition 2 *The integer $n > 1$ has*

- *first derivative 1 if $n = s$,*
- *second derivative 1 if $n = p^2 s$ where $p > 2$ and $p \nmid s$,*
- *third derivative 1 if $n = p^3 s$ where $p > 3$ and $p \nmid s$, or $n = p^3 q^2 s$ where $p > 3$, $q > 3$, $p \neq q$ and $(s, pq) = 1$.*

There are no other situations in which n has a derivative equal to 1.

The proof is a matter of recognising those situations in which 2^2 or 3^3 might arise as exact factors of terms in the derived sequence, and avoiding them since these factors will persist in subsequent differentiations.

It is also a matter of checking that 2- and 3-cycles are obtained in the following situations.

Proposition 3 *For any p,*

- *if p^2+1 is squarefree, then $\mathcal{D}(p^{p^2+1}) = \{\underline{p^{p^2+1}}, \underline{(p^2+1)p^{p^2}}, \dots\}$,*
- *if p^3+2 and p^3+1 are squarefree, then*

$$\mathcal{D}(p^{p^3+2}) = \{\underline{p^{p^3+2}}, \underline{(p^3+2)p^{p^3+1}}, \underline{(p^3+1)p^{p^3}}, \dots\}.$$

The underlined terms are cycles. Notice that 13, 37, 61, ..., are primes p such that p^3+2 and p^3+1 are squarefree. Certainly, 2- and 3-cycles may arise in other ways, as in the examples (4) and (5).

We can also give a general instance that leads to a 4-cycle:

Proposition 4 *Let s be such that $s \equiv 2 \pmod 3$, $4s-1$ is squarefree and $2s-1$ is squarefree. Then $\mathcal{D}(3^{4s})$ results in a 4-cycle.*

Proof. Write $4s-1 = s_1$ and $2s-1 = 3s_2$ (where $3 \nmid s_2$). If s is odd, then

$$\mathcal{D}(3^{4s}) = \{3^{4s}, 2^2 3^{4s-1} s, \underline{2^2 3^{4s-2} s_1}, \underline{2^3 3^{4s-2} s_2}, \underline{2^3 3^{4s-1} s_2}, \underline{2^2 3^{4s-1} s_1}, \dots\},$$

while if s is even, then

$$\mathcal{D}(3^{4s}) = \{3^{4s}, 2^3 3^{4s-1}(s/2), \underline{2^2 3^{4s-1} s_1}, \underline{2^2 3^{4s-2} s_1}, \underline{2^3 3^{4s-2} s_2}, \underline{2^3 3^{4s-1} s_2}, \dots\}.$$

The underlined terms in each case are 4-cycles (in fact, algebraically, the same 4-cycle). □

The smallest permissible value of s in this proposition is $s = 2$, as in the example (6); thereafter, s may take the values 11, 17, 26, 29, 35, ...

Other examples of 4-cycles are not difficult to find, and we need not always start at a prime power. For example:

$$\mathcal{D}(2^{10}3^{10}) = \{2^{10}3^{10}, \underline{2^{11}3^9 5^2}, \underline{2^{11}3^{10}5 \cdot 11}, \underline{2^{11}3^9 5 \cdot 11}, \underline{2^{10}3^{10} \cdot 11}, \dots\}.$$

It was initially more difficult to find examples of derived k-cycles for $k > 4$, but, having found a few, patterns were detected suggesting infinite families of these. Some are described in the following propositions. (We have other, more general, examples.)

Proposition 5 *Let s be such that $(s, 2\cdot 3\cdot 5\cdot 47) = 1$, and suppose $(s_1, 5\cdot 23\cdot 47) = 1$, where $s_1 = (3s-1)/2$. Put $n = 2^{3s}3^{45}5^5 23 s_1$. Then n, $D(n)$, ..., $D^4(n)$ is a 5-cycle.*

In this, s may take the values 1, 13, 23, 29, 41, 53, 61, ...

Proposition 6 (a) *Let s be such that $(s, 2\cdot3\cdot5\cdot7\cdot53) = 1$, and suppose $(s_1, 5\cdot53\cdot107) = 1$, where $s_1 = 6s+1$. Put $n = 2^{6s}3^{105}5^67s_1$. Then n, $D(n)$, ..., $D^5(n)$ is a 6-cycle.*

(b) *Let s be such that $(s, 2\cdot3\cdot5\cdot13\cdot43) = 1$, and suppose $(s_1, 7\cdot13\cdot43\cdot131) = 1$, where $s_1 = 30s+1$. Put $n = 2^{30s}3^{129}5^67\cdot43s_1$. Then n, $D(n)$, ..., $D^5(n)$ is a 6-cycle.*

Proof. As usual, the proofs are a matter of straightforward verification. We will demonstrate this in the case of Proposition 6(a). We have

$$\begin{aligned}
n &= 2^{6s}3^{105}5^67s_1, \\
D(n) &= 2^{6s+1}3^{107}5^67s, && \text{since } (s_1, 2\cdot3\cdot5\cdot7) = 1, \\
D^2(n) &= 2^{6s+1}3^{107}5^5107s_1, && \text{since } (s, 2\cdot3\cdot5\cdot7) = 1, \\
D^3(n) &= 2^{6s}3^{106}5^5107s_1, && \text{since } (s_1, 2\cdot3\cdot5\cdot107) = 1, \\
D^4(n) &= 2^{6s+1}3^{106}5^553s, && \text{since } (s_1, 2\cdot3\cdot5\cdot107) = 1, \\
D^5(n) &= 2^{6s+1}3^{105}5^553s_1, && \text{since } (s, 2\cdot3\cdot5\cdot53) = 1, \\
D^6(n) &= 2^{6s}3^{105}5^67s_1, && \text{since } (s_1, 2\cdot3\cdot5\cdot53) = 1.
\end{aligned}$$

But $D^6(n) = n$. We have also used the fact that s and s_1 are squarefree. □

In Proposition 6(a), we may have $s = 11$, 13, 17, 23, 31, 37, 41, ... In Proposition 6(b), s may take the values 1, 7, 11, 19, 23, 37, 41, ...

Proposition 7 *Let s be such that $s \equiv 7 \pmod{10}$ and $(s, 3\cdot23\cdot31\cdot47\cdot103\cdot311) = 1$, and suppose $(s_1, 3\cdot5\cdot31\cdot47\cdot103\cdot311) = 1$, where $s_1 = (2s+1)/5$. Put $n = 2^{2s}3^{311}5^{46}103s_1$. Then n, $D(n)$, ..., $D^7(n)$ is an 8-cycle.*

In this, s may take the values 17, 107, 167, 197, 227, ... Proposition 7 was found by observing that $\mathcal{D}(5^{13}29^{54})$ arrives in 428 iterations of D at the 8-cycle beginning with $29^{29}n$, with $s = 557$. Two other examples of 8-cycles turned up in our searches:

$$\begin{aligned}
&2^{159}3^{16725}5^579\cdot8363, && 2^{158}3^{16726}5^753\cdot223, \\
&2^{159}3^{16725}5^67\cdot79\cdot8363, && 2^{159}3^{16727}5^753\cdot223, \\
&2^{158}3^{16727}5^67\cdot43\cdot53\cdot389, && 2^{159}3^{16727}5^543\cdot79\cdot389, \\
&2^{158}3^{16727}5^543\cdot53\cdot389, && 2^{158}3^{16726}5^543\cdot79\cdot389,
\end{aligned}$$

and

$$\begin{aligned}
&2^{87}3^{149325}5^543\cdot197\cdot379, && 2^{86}3^{149326}5^711\cdot29\cdot181, \\
&2^{87}3^{149325}5^67\cdot43\cdot197\cdot379, && 2^{87}3^{149327}5^711\cdot29\cdot181, \\
&2^{86}3^{149327}5^67\cdot29\cdot31\cdot4817, && 2^{87}3^{149327}5^531\cdot43\cdot4817, \\
&2^{86}3^{149327}5^529\cdot31\cdot4817, && 2^{86}3^{149326}5^531\cdot43\cdot4817.
\end{aligned}$$

These occur in $\mathcal{D}(3^{16695})$ and $\mathcal{D}(3^{149319})$, respectively. It is not difficult to determine a two-parameter family, containing general exponents on 2 and 3, that includes both of these 8-cycles.

We have no examples of derived k-cycles with $k = 7$ or $k > 8$.

3 Bounded derived sequences

We have two results on the number of bounded derived sequences, the first resulting largely from a direct search, the second of a much more theoretical nature.

Proposition 8 *For all $n < 1.5 \cdot 10^{10}$, the derived sequence $\mathcal{D}(n)$ is bounded.*

Proof. The proof involved a direct incremental investigation of all numbers $n = \prod_{i=1}^{w} p_i^{a_i} < 1.5 \cdot 10^{10}$ for which $\sum_{i=1}^{w}(a_i - 1) \geq 8$. (An initial factorisation of each n determined whether this condition was satisfied.) In all cases, $\mathcal{D}(n)$ resulted in a cycle. We showed also that the same is true of all n with $\sum_{i=1}^{w}(a_i - 1) \leq 7$. For example, suppose $n = p^3q^2s$, where $p \neq q$ and $(s, pq) = 1$. If p and q are both greater than 3, then $D(n) = 2 \cdot 3p^2q$, $D^2(n) = 2p$ and $D^3(n) = 1$ (or use Proposition 2); then the numbers p^32^2s $(p > 3)$, p^33^2s $(p > 3)$, 2^3q^2s $(q > 3)$, 3^3q^2s $(q > 3)$, 2^33^2s and 3^32^2s must be separately and similarly considered. □

It would seem probable that $\mathcal{D}(n)$ is unbounded for some n, and in that case for all numbers ns, where $(n, s) = 1$, as well. Then the set of such numbers would have positive density in $\mathbb{N}$. We show now that this density is less than 0.004. We have computed lower bounds for the densities of 45 classes of integers, including the known result for the set of squarefree numbers, and have shown that integers in these 45 classes have bounded derived sequences. In each case, the density was computed to within 10^{-6} and then truncated to five decimal digits. Those densities (33 of the 45) which gave a positive lower bound (to that number of digits) are given in Table 1. We refer, for example, to the type p^3q^2S as the set of integers of the form p^3q^2s, where $p \neq q$ and $(s, pq) = 1$. How the given densities were obtained will be illustrated shortly by the determination of such for the type p^3q^2S. The 45 classes of integers were all possible types of the form $p^aq^b \cdots S$ such that $(a-1)+(b-1)+\cdots \leq 7$ (precisely as considered in the proof of Proposition 8), and Table 1 shows that their cumulative density is at least 0.996.

We show now how we obtain that the density of the class p^3q^2S is 0.01447, truncated to five decimal digits.

Let $x > 0$ be given. In general, the number of positive integers $n \leq x$, not divisible by the prime squares p_1^2, p_2^2, ..., p_l^2 and not divisible by the primes q_1, q_2, ..., q_m (all these being different primes) is

$$x \cdot \prod_{i=1}^{l}\left(1 - \frac{1}{p_i^2}\right) \cdot \prod_{i=1}^{m}\left(1 - \frac{1}{q_i}\right) + O(1).$$

Note that the positive integer $n \leq x$ is squarefree if $p^2 \nmid n$ for all primes $p \leq \sqrt{x}$. Fix distinct primes p and q. As above, the number of squarefree positive integers $n \leq x/p^3q^2$ which are divisible by neither p nor q is

$$\frac{x}{p^3q^2}\left(1-\frac{1}{p}\right)\left(1-\frac{1}{q}\right)\prod_{\substack{r\le\sqrt{x/p^3q^2}\\ r\neq p,\,q}}\left(1-\frac{1}{r^2}\right)+O(1)$$
$$=\frac{x}{p^3q^2}\left(1-\frac{1}{p}\right)\left(1-\frac{1}{q}\right)\left(1-\frac{1}{p^2}\right)^{-1}\left(1-\frac{1}{q^2}\right)^{-1}\prod_{r\le\sqrt{x/p^3q^2}}\left(1-\frac{1}{r^2}\right)+O(1)$$
$$=x\cdot\frac{1}{p^2(p+1)}\cdot\frac{1}{q(q+1)}\prod_{r\le\sqrt{x/p^3q^2}}\left(1-\frac{1}{r^2}\right)+O(1),$$

the products being taken over primes r.

In general, for $y>0$ we have $\prod_{r\le y}(1-1/r^2)=6/\pi^2+O(1/y)$. Applying this above, the number of squarefree positive integers $n\le x/p^3q^2$ which are divisible by neither p nor q is then

$$x\cdot\frac{1}{p^2(p+1)}\cdot\frac{1}{q(q+1)}\left(\frac{6}{\pi^2}+O\left(\sqrt{\frac{p^3q^2}{x}}\right)\right)+O(1)$$
$$=\frac{6x}{\pi^2}\cdot\frac{1}{p^2(p+1)}\cdot\frac{1}{q(q+1)}+O\left(\sqrt{\frac{x}{p^3q^2}}\right).$$

To find the number of positive integers $n\le x$ of the form $n=p^3q^2s$, where p, q are any two distinct primes and $(s,pq)=1$, we sum our result above over primes $p\le\sqrt[3]{x}$ and $q\le\sqrt{x/p^3}$. Therefore the proportion of these integers p^3q^2s which are at most x is given by

$$\frac{1}{x}\sum_{p\le\sqrt[3]{x}}\sum_{\substack{q\le\sqrt{x/p^3}\\ q\neq p}}\left(\frac{6x}{\pi^2}\cdot\frac{1}{p^2(p+1)}\cdot\frac{1}{q(q+1)}+O\left(\sqrt{\frac{x}{p^3q^2}}\right)\right)$$
$$=\sum_{p\le\sqrt[3]{x}}\sum_{\substack{q\le\sqrt{x/p^3}\\ q\neq p}}\frac{6}{\pi^2}\cdot\frac{1}{p^2(p+1)}\cdot\frac{1}{q(q+1)}+O\Bigg(\sum_{p\le\sqrt[3]{x}}\sum_{q\le\sqrt{x/p^3}}\frac{1}{\sqrt{xp^3q^2}}\Bigg).$$

In general, $\sum_{p\le y}1/p^{3/2}=O(1)$ and $\sum_{q\le y}1/q=O(\log\log y)$, and so

$$O\Bigg(\sum_{p\le\sqrt[3]{x}}\sum_{q\le\sqrt{x/p^3}}\frac{1}{\sqrt{xp^3q^2}}\Bigg)=O\Bigg(\frac{1}{\sqrt{x}}\sum_{p\le\sqrt[3]{x}}\frac{1}{\sqrt{p^3}}\sum_{q\le\sqrt{x}}\frac{1}{q}\Bigg)=O\Bigg(\frac{\log\log x}{\sqrt{x}}\Bigg).$$

Thus the required density is

$$\lim_{x\to\infty}\sum_{p\le\sqrt[3]{x}}\sum_{\substack{q\le\sqrt{x/p^3}\\ q\neq p}}\frac{6}{\pi^2}\cdot\frac{1}{p^2(p+1)}\cdot\frac{1}{q(q+1)}=\frac{6}{\pi^2}\sum_{p}\frac{1}{p^2(p+1)}\sum_{q\neq p}\frac{1}{q(q+1)}\ge 0.0144.$$

The double sum was estimated on a computer.

We have therefore shown the following:

Type	*Density*	*Truncated density*
S	$\frac{\pi^2}{6}$	0.60792

Table 1: Densities giving a positive lower bound

Proposition 9 *The density in* $\mathbb{N}$ *of integers* n *for which* $\mathcal{D}(n)$ *is unbounded is less than* 0.004.

Although we cannot exhibit an unbounded derived sequence, we do have the following result.

Proposition 10 *For any positive integer* M*, there exists an integer* n *such that* $\mathcal{D}(n)$ *requires more than* M *iterations of* D *before a cycle is possible.*

Proof. Let p be a large prime, with "large" to be qualified shortly. Take $n = p^{4p}$. Then

$$\mathcal{D}(n) = \{p^{4p}, 2^2p^{4p}, 2^4p^{4p}, 2^7p^{4p}, 2^87p^{4p}, 2^{12}p^{4p}, 2^{15}3p^{4p}, \dots\}.$$

The exact factor p^{4p} will persist in all terms until the exponent on 2 or some other prime (not p) equals p. Until this happens, if it will ever happen, there can be no derived k-cycle in $\mathcal{D}(n)$, for any k. For suppose there were such a cycle and let the ith term of the cycle be $\prod p_i^{a_i}$, $1 \le i \le k$, where the notation is as in Proposition 1. It follows that at most 2^k divides $\prod p_1 \prod p_2 \cdots \prod p_k$, while at least 2^{2k} divides $\prod a_1 \prod a_2 \cdots \prod a_k$. By Proposition 1, this is a contradiction. The proof is non-constructive, in that we can say only that, whatever the value of M, a prime p exists such that p exceeds all exponents on primes other than p resulting from M iterations of D. $\square$

4 Further work

(1) Find examples of integers n for which $\mathcal{D}(n)$ results in a k-cycle for $k = 7$ or $k > 8$. Do derived k-cycles exist for all positive integers k?

(2) Can it be shown that $\mathcal{D}(n)$ is unbounded for some n, as we have conjectured above? We suspect this to be the case for "most" sequences $\mathcal{D}(p^{q^p})$ $(p \neq q)$, for reasons suggested in the proof of Proposition 10 (where we considered $q = 2$). It is not known whether $\mathcal{D}(7^{4046})$, $\mathcal{D}(11^{1674})$ and $\mathcal{D}(13^{504})$ are bounded, but this is the case for all smaller exponents on the respective primes. (It took a few weeks for referee's comments to be returned. We are grateful for those. In that time we left a program running, checking $\mathcal{D}(31^{124})$ for boundedness. After $k = 48218701$ iterations, we found no cycle and $D^k(31^{124}) = 2^{1516268557}3^{780548532}5^{348780008} \cdots 127^{10414}131^{131}139^{139}149^{141851} \cdots 62763353 \cdot 348779999$, with all primes up to 131 present. The program was then permanently halted.)

(3) As in the calculus, differentiation is a craft, but integration is an art. Can a technique be developed for finding integrals of a given positive integer or of showing that certain integers, the primes being examples, have no integrals? In Proposition 2, we have given all integrals of 1, but even to identify all integrals of 4 seems to be very difficult.

Abstract

In this paper we introduce some formulas for the number of derangements. Then we define the derangement function and use the software package MAPLE to obtain some integrals related to the incomplete gamma function and also to some hypergeometric summations.

1 Introduction and motivation

A permutation of $S_n = \{1, 2, 3, \cdots, n\}$ that has no fixed points is a *derangement* of S_n. Let D_n denote the number of derangements of S_n. It is well-known that

$$D_n = n! \sum_{i=0}^{n} \frac{(-1)^i}{i!}, \tag{1}$$

$$D_n = \| \frac{n!}{e} \| \quad (\| \ \| \text{ denotes the nearest integer}). \tag{2}$$

We can rewrite (2) as follows:

$$D_n = \lfloor \frac{n!}{e} + \frac{1}{2} \rfloor.$$

We can generalize the above formula replacing $\frac{1}{2}$ by every $m \in [\frac{1}{3}, \frac{1}{2}]$. In fact we have:

Theorem 1.1 *Suppose $n \geq 1$ is an integer, we have*

$$D_n = \begin{cases} \lfloor \frac{n!}{e} + m_1 \rfloor, & n \text{ is odd}, m_1 \in [0, \frac{1}{2}]; \\ \lfloor \frac{n!}{e} + m_2 \rfloor, & n \text{ is even}, m_2 \in [\frac{1}{3}, 1]. \end{cases} \tag{3}$$

For a proof of this theorem, see Hassani [3]. At the end of the next section we give another proof of it.

On the other hand, the idea of proving (2) leads to a family of formulas for the number of derangements, as follows: we have

$$|\frac{n!}{e} - D_n| \leq \frac{1}{(n+1)} + \frac{1}{(n+1)(n+2)} + \frac{1}{(n+1)(n+2)(n+3)} + \cdots .$$

Let $M(n)$ denote the right side of above inequality. We have

$$M(n) < \frac{1}{(n+1)} + \frac{1}{(n+1)^2} + \cdots = \frac{1}{n},$$

and therefore

$$D_n = \lfloor \frac{n!}{e} + \frac{1}{n} \rfloor \quad (n \geq 2). \tag{4}$$

Also we can get a better bound for $M(n)$ as follows

$$M(n) < \frac{1}{n+1}(1 + \frac{1}{(n+2)} + \frac{1}{(n+2)^2} + \cdots) = \frac{n+2}{(n+1)^2},$$

and similarly

$$D_n = \lfloor \frac{n!}{e} + \frac{n+2}{(n+1)^2} \rfloor \quad (n \geq 2). \tag{5}$$

The above idea is extensible, but before extending we recall a useful formula (see [2, 3]). For every positive integer $n \geq 1$, we have

$$\sum_{i=0}^{n} \frac{n!}{i!} = \lfloor en! \rfloor. \tag{6}$$

2 New families and some other formulas

Theorem 2.1 *Suppose m is an integer and $m \geq 3$. The number of derangements of n distinct objects $(n \geq 2)$ is*

$$D_n = \lfloor (\frac{\lfloor e(n+m-2)! \rfloor}{(n+m-2)!} + \frac{n+m}{(n+m-1)(n+m-1)!} + e^{-1})n! \rfloor - \lfloor en! \rfloor. \tag{7}$$

Proof: For $m \geq 3$ we have

$$|\frac{n!}{e} - D_n| < \frac{1}{(n+1)}(1 + \frac{1}{(n+2)}(\cdots 1 + \frac{1}{(n+m-1)}(\frac{n+m}{n+m-1})\cdots)).$$

Let $M_m(n)$ denote the right side of the above inequality; we have

$$(n+1)(n+2)(n+3)\cdots(n+m-1)M_m(n) =$$

$$(n+2)(n+3)\cdots(n+m-1) + (n+3)\cdots(n+m-1) + \cdots + (n+m-1) + \frac{n+m}{n+m-1},$$

and dividing by $(n+1)(n+2)(n+3)\cdots(n+m-1)$ we obtain

$$M_m(n) = n!(\frac{n+m}{(n+m-1)(n+m-1)!} + \sum_{i=n+1}^{n+m-2} \frac{1}{i!}).$$

Therefore

$$D_n = \lfloor \frac{n!}{e} + n!(\frac{n+m}{(n+m-1)(n+m-1)!} + \sum_{i=n+1}^{n+m-2} \frac{1}{i!}) \rfloor. \tag{8}$$

Now consider (6) and rewrite (8) by using $\sum_{i=n+1}^{n+m-2} \frac{1}{i!} = \sum_{i=0}^{n+m-2} \frac{1}{i!} - \sum_{i=0}^{n} \frac{1}{i!}$. The proof is complete. □

Corollary 2.2 *For $n \geq 2$, we have*

$$D_n = \lfloor (e + e^{-1})n! \rfloor - \lfloor en! \rfloor. \tag{9}$$

Proof: We give two proofs.
Method 1. Because (7) holds for all $m \geq 3$, we have

$$D_n = \lim_{m\to\infty} \lfloor (\frac{\lfloor e(n+m-2)! \rfloor}{(n+m-2)!} + \frac{n+m}{(n+m-1)(n+m-1)!} + e^{-1})n! \rfloor - \lfloor en! \rfloor$$

$$= \lfloor (e + e^{-1})n! \rfloor - \lfloor en! \rfloor.$$

Method 2. By using (6), we have

$$M(n) = n!(e - \sum_{i=0}^{n} \frac{1}{i!}) = en! - \lfloor en! \rfloor = \{en!\} \quad (n \geq 1, \{\ \} \text{ denotes the fractional part}),$$

and the proof follows. □

Now

$$\lim_{m\to\infty} M_m(n) = M(n),$$

and if we put $M_1(n) = \frac{1}{n}$ and $M_2(n) = \frac{n+2}{(n+1)^2}$ (see formulas (4) and (5)), then

$$M_{m+1}(n) < M_m(n) \quad (n \geq 1).$$

Now we find bounds sharper than $\{en!\}$ for $e^{-1}n! - D_n$ and consequently another family of formulas for D_n. This family is an extension of (9).

Theorem 2.3 *Suppose m is an integer and $m \geq 1$. The number of derangements of n distinct objects ($n \geq 2$) is*

$$D_n = \lfloor (\frac{\{e(n+2m)!\}}{(n+2m)!} + \sum_{i=1}^{m} \frac{n+2i-1}{(n+2i)!} + e^{-1})n! \rfloor. \tag{10}$$

Proof: Since $m \geq 1$ we have

$$\frac{e^{-1}n! - D_n}{(-1)^{n+1}} = n! \sum_{i=1}^{\infty} (\frac{1}{(n+2i-1)!} - \frac{1}{(n+2i)!}) < n! (\sum_{i=1}^{m} \frac{n+2i-1}{(n+2i)!} + \sum_{i=2m+1}^{\infty} \frac{1}{(n+i)!}).$$

Let $N_m(n)$ denote the right member of above inequality. Considering (6), we have

$$N_m(n) = n! (\sum_{i=1}^{m} \frac{n+2i-1}{(n+2i)!} + \frac{\{e(n+2m)!\}}{(n+2m)!}),$$

and for ($n \geq 2$), $D_n = \lfloor e^{-1}n! + N_m(n) \rfloor$. This completes the proof. □

Corollary 2.4 *For all integers $m, n \geq 1$, we have*

$$N_{m+1}(n) < N_m(n), \quad N_1(n) < \{en!\}.$$

Therefore we have the following chain of bounds for $|\frac{n!}{e} - D_n|$

$$|\frac{n!}{e} - D_n| < \cdots < N_2(n) < N_1(n) < \{en!\} < \cdots < M_2(n) < M_1(n) < 1 \quad (n \geq 2).$$

Question 1. Can we find the following limit?

$$\lim_{m \to \infty} N_m(n).$$

Before going to the next section we give our proof of Theorem 1. The idea of present proof is hidden in Apostol's analysis [1], where he proved the irrationality of e by using (11). And now,

Proof: (Proof of Theorem 1) Suppose $k \geq 1$ be an integer, we have

$$0 < \frac{1}{e} - \sum_{i=0}^{2k-1} \frac{(-1)^i}{i!} < \frac{1}{(2k)!} \tag{11}$$

so, for every m_1, we have

$$m_1 < \frac{(2k-1)!}{e} + m_1 - \sum_{i=0}^{2k-1} \frac{(-1)^i (2k-1)!}{i!} < m_1 + \frac{1}{2}$$

if $0 \leq m_1 \leq \frac{1}{2}$, then

$$\sum_{i=0}^{2k-1} \frac{(-1)^i(2k-1)!}{i!} = \lfloor \frac{(2k-1)!}{e} + m_1 \rfloor.$$

Similarly since (11), for every m_2 we have

$$m_2 - 1 < \frac{(2k)!}{e} + m_2 - \sum_{i=0}^{2k} \frac{(-1)^i(2k)!}{i!} < m_2.$$

Now, if $m_2 \geq \frac{1}{3}$, then

$$0 < \frac{(2k)!}{e} + m_2 - \sum_{i=0}^{2k} \frac{(-1)^i(2k)!}{i!}$$

therefore, if $\frac{1}{3} \leq m_2 \leq 1$, we obtain

$$\sum_{i=0}^{2k} \frac{(-1)^i(2k)!}{i!} = \lfloor \frac{(2k)!}{e} + m_2 \rfloor.$$

This completes the proof. □

In the next section there are some applications of the proven results.

3 The derangement function, incomplete gamma and hypergeometric functions

Let's find other formulas for D_n. The computer algebra program MAPLE yields that

$$D_n = (-1)^n \texttt{hypergeom}([1, -n], [\ ], 1),$$

and

$$D_n = e^{-1}\Gamma(n+1, -1),$$

where $\texttt{hypergeom}([1, -n], [\ ], 1)$ is MAPLE's notation for a hypergeometric function. More generally, $\texttt{hypergeom}([a_1\ \ a_2\ \cdots\ a_p], [b_1\ \ b_2\ \cdots\ b_q], x)$ is defined as follows (see [4]),

$${}_pF_q\left[\begin{array}{cccc} a_1 & a_2 & \cdots & a_p \\ b_1 & b_2 & \cdots & b_q \end{array}; x\right] = \sum_{k\geq 0} t_k x^k$$

where

$$\frac{t_{k+1}}{t_k} = \frac{(k+a_1)(k+a_2)\cdots(k+a_p)}{(k+b_1)(k+b_2)\cdots(k+b_q)(k+1)}x.$$

Also $\Gamma(n+1, -1)$ is an incomplete gamma function and generally defined as follows:

$$\Gamma(a, z) = \int_z^\infty e^{-t}t^{a-1}dt \quad (Re(a) > 0),$$

Now, because we know the value of D_n, we can estimate some summations and integrals. To do this, we define the *derangement function*, a natural generalization of derangements, denoted by $D_n(x)$, for every integer $n \geq 0$ and every real x as follows:

$$D_n(x) = \begin{cases} n! \sum_{i=0}^{n} \frac{x^i}{i!}, & x \neq 0; \\ n!, & x = 0. \end{cases}$$

It is easy to obtain the following generalized recursive relations:

$$D_n(x) = (x+n)D_{n-1}(x) - x(n-1)D_{n-2}(x) = x^n + nD_{n-1}(x), \quad (D_0(x) = 1, D_1(x) = x+1).$$

Note that $D_n(x)$ is a nice polynomial. Its value for $x = -1$ is D_n, for $x = 0$ is the number of permutations of n distinct objects and for $x = 1$ is w_{n+2} = the number of distinct paths between every pair of vertices in a complete graph on $n+2$ vertices, and

$$D_n(1) = \lfloor en! \rfloor \quad (n \geq 1), \quad \text{(see [3])}.$$

A natural question is

Question 2. Is there any combinatorial meaning for the value of $D_n(x)$ for other values of x?

The above definitions yield

$$D_n(x) = x^n \, {}_2F_0 \left[\begin{array}{cc} 1 & -n \\ - & \end{array} ; -\frac{1}{x} \right] \quad (x \neq 0),$$

and

$$D_n(x) = e^x \Gamma(n+1, x). \tag{12}$$

We obtain

$${}_2F_0 \left[\begin{array}{cc} 1 & -n \\ - & \end{array} ; -1 \right] = \lfloor en! \rfloor,$$

and

$${}_2F_0 \left[\begin{array}{cc} 1 & -n \\ - & \end{array} ; 1 \right] = (-1)^n \left\lfloor \frac{n!+1}{e} \right\rfloor.$$

Also we have some corollaries.

Corollary 3.1 *For every real $x \neq 0$ we have*

$${}_1F_1 \left[\begin{array}{c} n+1 \\ n+2 \end{array} ; -x \right] = \frac{(n+1)(n! - e^{-x} D_n(x))}{x^{n+1}}.$$

Proof: Obvious. □

Corollary 3.2 *For every integer $n \geq 1$ we have*

$$\int_{-1}^{\infty} e^{-t}t^n dt = e\left\lfloor \frac{n!+1}{e} \right\rfloor,$$

$$\int_{0}^{\infty} e^{-t}t^n dt = n!,$$

$$\int_{1}^{\infty} e^{-t}t^n dt = \frac{\lfloor en! \rfloor}{e},$$

and

$$\int_{0}^{1} e^{-t}t^n dt = \frac{\{en!\}}{e},$$

$$\int_{-1}^{0} e^{-t}t^n dt = \begin{cases} -e\{\frac{n!}{e}\} & n \text{ is odd}, \\ e - e\{\frac{n!}{e}\} & n \text{ is even}. \end{cases}$$

$$\int_{-1}^{1} e^{-t}t^n dt = e\lfloor (e+e^{-1})n! \rfloor - (e+e^{-1})\lfloor en! \rfloor,$$

Proof: Use relations (3), (6), (9), (12) and the definition of derangement function in the case $x = 0$. □

Question 3. Are there any similar formulas for ${}_2F_0\left[\begin{array}{cc} 1 & -n \\ - & \end{array}; -\frac{1}{x}\right]$? In other words, given any real number x, is there an interval I (dependent on x) such that

$$n!\sum_{i=0}^{n}\frac{x^i}{i!} = \lfloor e^x n! + m \rfloor \quad (m \in I_x)?$$

4 Acknowledgements

I would like to express my gratitude to Dr. J. Rooin for his valuable guidance. Also I thank the referee for his/her priceless comments on the third section.

Abstract: We define a multiplicative arithmetic function *D* by assigning *D(p^a)=ap^{a-1}*, when *p* is a prime and *a* is a positive integer, and, for *n* >= 1, we set *D^0(n)=n* and *D^k(n)=D(D^{k-1}(n))* when *k*>= 1. We term *{D^k(n)}_{k >= 0}* the derived sequence of *n*. We show that all derived sequences of *n* < 1.5 * 10^10 are bounded, and that the density of those *n* in **N** with bounded derived sequences exceeds 0.996, but we conjecture nonetheless the existence of unbounded sequences. Known bounded derived sequences end (effectively) in cycles of lengths only 1 to 6, and 8, yet the existence of cycles of arbitrary length is conjectured. We prove the existence of derived sequences of arbitrarily many terms without a cycle.

A NOTE ON ARITHMETIC PROGRESSIONS ON ELLIPTIC CURVES

Garikai Campbell

Department of Mathematics and Statistics
Swarthmore College
Swarthmore, PA 19081
USA

Abstract. Andrew Bremner (*Experiment. Math.* **8** (1999), 409–413) has described a technique for producing infinite families of elliptic curves containing length 7 and length 8 arithmetic progressions. This note describes another way to produce infinite families of elliptic curves containing length 7 and length 8 arithmetic progressions. We illustrate how the technique articulated here gives an easy way to produce an elliptic curve containing a length 12 progression and an infinite family of elliptic curves containing a length 9 progression, with the caveat that these curves are not in Weierstrass form.

1. Introduction.

There are two (affine) models of elliptic curve that are very common. They are $y^2 = f(x)$ where $f(x)$ is either a cubic or a quartic. We will say that *points on a particular model of an elliptic curve are in arithmetic progression* if their x-coordinates form an arithmetic progression. For example, Buhler, Gross and Zagier [3] found that the points $(-3, 0)$, $(-2, 3)$, $(-1, 3)$, $(0, 2)$, $(1, 0)$, $(2, 0)$, $(3, 3)$, and $(4, 6)$ form an arithmetic progression of length 8 on the curve $y^2 + y = (x - 1)(x - 2)(x + 3)$. Moreover, Bremner [2] proves:

Theorem 1.1. *Each point on the elliptic curve*

$$C : y^2 = x^3 - x^2 - 36x + 36$$

corresponds to an elliptic curve in Weierstrass form containing at least 8 points in arithmetic progression.

Before proving this theorem, Bremner considers the following strategy. First he remarks that any monic degree 8 polynomial, $P(x)$, can be written as $Q(x)^2 - R(x)$ where the degree of $R(x)$ is less than or equal to 3. If $R(x)$ has degree precisely 3 and no repeated zeros, then $y^2 = R(x)$ is an elliptic curve and for each zero, α, of $P(x)$, this elliptic curve contains a pair of points with x-coordinate α. So one possible strategy for producing an elliptic curve with an arithmetic progression of length 8 might be to let $P(x) = x(x+1)(x+2)\cdots(x+7)$ and compute the corresponding $R(x)$ so that $P(x) = Q(x)^2 - R(x)$. Unfortunately, in this case, $R(x)$ is linear and so this strategy fails for *any* degree 8 polynomial whose zeros form an arithmetic progression. The goal of this note is to illustrate how to turn this strategy into a successful one.

2. Arithmetic Progressions of Length 8

The statement that a degree 8 polynomial can be written as $Q(x)^2 - P(x)$ is a special case of the following:

Proposition 2.1. *If $P(x)$ is a monic polynomial of degree $2n$ defined over a field k, then there are unique polynomials $Q(x)$ and $R(x)$ defined over k such that*

(1) *$P(x) = Q(x)^2 - R(x)$ and*
(2) *the degree of $R(x)$ is strictly less than n.*

Since $R(x)$ is a square at every zero of $P(x)$, if $R(x)$ is a cubic or a quartic with no repeated zeros, then we can produce elliptic curves $y^2 = R(x)$ with great control over many of the x-coordinates.

Remark 2.2. We note that Mestre [9] was first to observe that this relatively simple proposition could be used to produce elliptic curves of large rank. Since Mestre's first paper exploiting this idea, many others ([4], [6], [7], [8], [11]) have used the proposition in clever ways to produce elliptic curves and infinite families of elliptic curves with the largest known rank (often with some condition on the torsion subgroup).

Now consider the polynomial

$$p_t(x) = (x-t)^2 \prod_{j=0}^{5} (x-j) \ \in \mathbb{Q}(t)[x].$$

In this case, we can write

$$p_t(x) = q_t(x)^2 - f_t(x),$$

where $f_t(x)$ is a polynomial of degree 3 in $\mathbb{Q}(t)[x]$ such that

(1) the discriminant of $f_t(x)$ is an irreducible polynomial in $\mathbb{Q}[t]$
(2) the coefficient of x^3 is $c(2t-5)$, where $c \in \mathbb{Q}$.

Therefore, we have that

Theorem 2.3. *The curve E_t defined by $y^2 = f_t(x)$ is an elliptic curve defined over $\mathbb{Q}(t)$, containing at least six points in arithmetic progression and for each $t_0 \in \mathbb{Q}$, $t_0 \neq 5/2$, the specialization of E_t at $t = t_0$ gives an elliptic curve defined over $\mathbb{Q}$ containing at least six points in arithmetic progression.*

We next observe that $f_t(6)$ is a conic in $\mathbb{Q}[t]$ which is a rational square when $t = 6$. Therefore, we can parameterize all rational solutions to $y^2 = f_t(6)$ by letting

$$t \ = \ \frac{6m^2 - 126m - 285360}{m^2 - 72256}. \tag{2.1}$$

Since no rational value of m gives $t = 5/2$, we have:

Corrolary 2.4. *Let $g_m(x)$ be the polynomial $f_t(x)$ with t given by (2.1). The curve E_m defined by $y^2 = g_m(x)$ is an elliptic curve defined over $\mathbb{Q}(m)$ containing at least seven points in arithmetic progression and for each $m_0 \in \mathbb{Q}$, the specialization of E_m at $m = m_0$ gives an elliptic curve defined over $\mathbb{Q}$ containing at least seven points in arithmetic progression.*

If we continue in this vein and explore the conditions imposed by $y^2 = g_m(7)$, we find the following.

Theorem 2.5. *Let D be the elliptic curve defined by*

$$\begin{aligned} D : y^2 = &-264815m^4 - 19343520m^3 + 62846856064m^2 \\ &-2906312951808m - 495507443511296. \end{aligned}$$

Let

$$\begin{aligned} g_3 &= -18816m^4 + 677376m^3 + 1922543616m^2 \\ &\quad -48944480256m - 40678301368320, \\ g_2 &= 236896m^4 - 9821952m^3 - 22598349824m^2 \\ &\quad +508953231360m + 520252184657920, \\ g_1 &= -958800m^4 + 40985280m^3 + 89932669440m^2 \\ &\quad -1957723729920m - 2113363439616000, \ \textit{and} \\ g_0 &= 1292769m^4 - 57304800m^3 - 118795148928m^2 \\ &\quad +2647001548800m + 2758336954896384. \end{aligned}$$

Then

$$E'_m : y^2 = g_3\ x^3 + g_2\ x^2 + g_1\ x + g_0,$$

is an elliptic curve defined over $\mathbb{Q}(D)$ containing the 8 points in arithmetic progression with x-coordinates 0, 1, 2, ... , 7.

Proof. E'_m is isomorphic to E_m via the change of variables $y \mapsto y/(m^2 - 72256)$. Substituting $x = 7$ into E'_m, we get the curve D. □

Moreover, if we let $D(\mathbb{Q})$ be the group of rational points on D, then we have that $D(\mathbb{Q})$ is infinite. More specifically, we have:

Proposition 2.6. *D has rank 2 and torsion subgroup $\mathbb{Z}/2\mathbb{Z}$.*

Proof. A short computer search reveals that $O = (-88, 15628032)$ is a point in $D(\mathbb{Q})$. Taking O taken to be the identity, $D(\mathbb{Q})$ is generated by

$$\begin{aligned} P_0 &= (10984/79, -80015523840/6241) \text{ and} \\ P_1 &= (-1363640/2531, 31969540657152/6405961), \end{aligned}$$

and contains the point of order two:

$$P_2 = (10984/79, 80015523840/6241).$$

□

(The calculations above were performed with the help of `mwrank` [5] and GP [1].)

An immediate consequence of the proposition above is the following:

Corrolary 2.7. *Each point on the elliptic curve D corresponds to an elliptic curve in Weierstrass form containing at least 8 points in arithmetic progression.*

Remark 2.8. This condition is very similar to the condition found in Bremner's construction– namely, that points on the curve C give rise to elliptic curves with 8 points in arithmetic progression. The differences are that C has rank 1 and torsion subgroup $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}$, while D has rank 2 and torsion subgroup $\mathbb{Z}/2\mathbb{Z}$.

3. Longer Progressions

This construction can also be used to produce progressions of length greater than 8 on elliptic curves of the form $y^2 = f(x)$ where $f(x)$ is a quartic. More specifically, we have:

Theorem 3.1. *There exists an elliptic curve in the form $y^2 = w(x)$, with $w(x)$ a quartic, containing 12 points in arithmetic progression.*

Proof. Let

$$g_0(x) = \prod_{j=0}^{11}(x-j).$$

Then $g_0(x) = u_0(x)^2 - (81/4)\cdot v_0(x)$, with

$$\begin{aligned} u_0(x) &= x^6 - 33x^5 + 418x^4 - 2541x^3 + (14993/2)x^2 \\ &\quad -(18513/2)x + (4851/2), \text{ and} \\ v_0(x) &= 429x^4 - 9438x^3 + 74295x^2 - 246246x + 290521. \end{aligned}$$

Since the discriminant of $v_0(x)$ is nonzero, the curve $E : y^2 = v_0(x)$ is an elliptic curve. This elliptic curve then contains a length 12 arithmetic progression. □

(Note that by using `mwrank`, we computed the rank of this curve to be 4 with torsion subgroup $\mathbb{Z}/2\mathbb{Z}$.)

The construction above produces a single curve and it is unclear how to produce an infinite family of curves containing a length 12 progression using this idea. The problem is that, in general, if the $P(x)$ of proposition 2.1 is taken to have degree 12, then the $R(x)$ is only guaranteed to have degree less than or equal to 5, not 4. Therefore, the curve $y^2 = R(x)$ need not be an elliptic curve. We can, however, prove the following.

Theorem 3.2. *There are infinitely many elliptic curves of the form $y^2 = w(x)$, with $w(x)$ a quartic, containing 9 points in arithmetic progression.*

Proof. Let

$$g(x) = (x-a)\cdot\prod_{j=0}^{8}(x-j),$$

and write $g(x)$ as $u(x)^2 - v(x)$. $v(x)$ is a degree four polynomial in $\mathbb{Q}(a)[x]$ with discriminant zero only for $a \in \{0, 4, 8\}$. □

The work here (and that of Bremner) leaves open the following questions:

Open Question 3.3. *Is there an elliptic curve of the form $y^2 = f(x)$, $f(x)$ a cubic, containing a length 9 arithmetic progression? Are there infinitely many?*

Open Question 3.4. *Is there an elliptic curve of the form* $y^2 = f(x)$, $f(x)$ *a quartic, containing a length 13 arithmetic progression? Are there infinitely many curves in this form containing a length 10 progression?*

And finally,

Open Question 3.5. *What is the longest arithmetic progression one can find on an elliptic curve in the form* $y^2 = f(x)$, *where* $f(x)$ *is a cubic? a quartic?*

Abstract

This paper shows the equivalence of various integer functions to the integer sequence A002620, and to the maximum of the product of certain pairs of combinatorial or graphical invariants. This maximum is the same as the upper bound of the Nordhaus-Gaddum inequality and related to Turán's number. The computer algebra program `MAPLE` *is used for solutions of linear recurrence and differential equations in some of the proofs. Chapter three of* The Encyclopedia of Integer Sequences *by Sloane and Plouffe describes the usefulness of apparently different expressions of an integer sequence.*

Define $\lfloor r \rfloor$, the floor of r, to be the largest integer less than or equal to a real number r, and $\lceil r \rceil$, the ceiling of r, the smallest integer greater than or equal to r. For manipulations of floor and ceiling operations, see chapter three of [20], and for graph theory terms see [10, 13, 21].

Theorem 1.1 *For n a positive integer the expressions in the following 29 paragraphs are equal. (for $n = 0$ see the comment at the end of this list)*

1. *The n^{th} term of the infinite sequence* $1, 2, 4, 6, 9, 12, 16, 20, 25, 30, 36, 42, 49, 56, 64, 72, 81, \ldots$ *which is sequence A002620 of the The On-Line Encyclopedia of Integer Sequences* (OEIS) [31] *without the leading zeros. See the comment at end of this list.*

2. $\begin{cases} k^2, & n = 2k-1 \\ k(k+1), & n = 2k \end{cases} = \begin{cases} \sum_{i=1}^{k}(2i-1), & n = 2k-1 \\ \sum_{i=1}^{k} 2k, & n = 2k \end{cases} = \begin{cases} \frac{(n+1)^2}{4}, & n \text{ odd} \\ \frac{(n+1)^2-1}{4}, & n \text{ even} \end{cases} = \frac{n^2}{4} + \frac{n}{2} + \frac{1-(-1)^n}{8}.$

3. $\left\lfloor (\frac{n+1}{2})^2 \right\rfloor = \left\lceil \frac{(n+1)^2-1}{4} \right\rceil = \left\lfloor (\frac{n+1}{2}) \right\rfloor + \left\lfloor (\frac{n}{2})^2 \right\rfloor = \left\lceil (\frac{n-1}{2}) \right\rceil + \left\lceil (\frac{n}{2})^2 \right\rceil.$

4. $\left\lfloor \frac{n+1}{2} \right\rfloor \cdot \left\lceil \frac{n+1}{2} \right\rceil = \left\lfloor \frac{n+1}{2} \right\rfloor \cdot \left(\left\lfloor \frac{n+1}{2} \right\rfloor + \begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases} \right) = \left\lfloor \frac{n+1}{2} \right\rfloor \cdot \left\lfloor \frac{n+2}{2} \right\rfloor = \left\lceil \frac{n}{2} \right\rceil \cdot \left\lceil \frac{n+1}{2} \right\rceil = \left\lceil \frac{n}{2} \right\rceil \cdot \left(\left\lceil \frac{n}{2} \right\rceil + \begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases} \right) = \left\lceil \frac{n+1}{2} \right\rceil \cdot \left(\left\lceil \frac{n+1}{2} \right\rceil - \begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases} \right).$

5. $\sum_{k=0}^{n-1} \left\lfloor \frac{k+2}{2} \right\rfloor = \sum_{k=1}^{n} \left\lfloor \frac{k+1}{2} \right\rfloor = \sum_{k=2}^{n+1} \left\lfloor \frac{k}{2} \right\rfloor = n + \sum_{k=2}^{n-1} \left\lfloor \frac{k}{2} \right\rfloor = \sum_{k=1}^{n} \left\lceil \frac{k}{2} \right\rceil.$

6. $\sum_{k=0}^{\lfloor \frac{n-1}{2} \rfloor}(n-2k) = n+(n-1)\left\lfloor \frac{n-1}{2} \right\rfloor - \left\lfloor \frac{n-1}{2} \right\rfloor^2 = \left(n+1-\left\lfloor \frac{n+1}{2} \right\rfloor\right)\left\lfloor \frac{n+1}{2} \right\rfloor = \sum_{k=\lfloor \frac{n+1}{2} \rfloor+1}^{n+1}(2k-n-2) =$
$\sum_{k=0}^{\lceil \frac{n-1}{2} \rceil}(n-2k) = n+(n-1)\left\lceil \frac{n-1}{2} \right\rceil - \left\lceil \frac{n-1}{2} \right\rceil^2 = \left(n+1-\left\lceil \frac{n+1}{2} \right\rceil\right)\left\lceil \frac{n+1}{2} \right\rceil = \sum_{k=\lceil \frac{n+1}{2} \rceil+1}^{n+1}(2k-n-2) =$
$\sum_{k=\lfloor \frac{n+2}{2} \rfloor}^{n}(2k-n) = \sum_{k=\lceil \frac{n+1}{2} \rceil}^{n}(2k-n) = \sum_{k=1}^{\lfloor \frac{n+1}{2} \rfloor} 2k - \begin{cases} \lfloor \frac{n+1}{2} \rfloor, & \text{if } n \text{ odd} \\ 0, & \text{if } n \text{ even} \end{cases} = \sum_{k=1}^{\lceil \frac{n+1}{2} \rceil}(2k-1) - \begin{cases} 0, & \text{if } n \text{ odd} \\ \lceil \frac{n+1}{2} \rceil, & \text{if } n \text{ even} \end{cases}.$

7. *The coefficient of x^n in the power series expansion of* $\frac{x}{1-2x+2x^3-x^4} = \frac{x}{(1+x)(1-x)^3} = \frac{1}{(1-x)^2}\sum_{k=1}^{\infty} x^{2k-1}$. *This is the generating function of the sequence.*

8. ***recurrence equations.*** *The n^{th} term of the sequence $\langle a(k) \rangle_{k=1}^{\infty}$ which is the solution of **any** of the following recurrence equations for all positive integers k :*

   (a) $a(k+1) + a(k) = \binom{k+2}{2} = \frac{(k+2)(k+1)}{2}$ *with* $a(1) = 1$.

   (b) $a(k+2) = a(k) + k + 2$ *with* $a(1) = 1$, $a(2) = 2$.

   (c) $a(k+3) = a(k+2) + a(k+1) - a(k) + 1$ *with* $a(1) = 1$, $a(2) = 2$, $a(3) = 4$.

   (d) $a(k+4) = 2a(k+3) - 2a(k+1) + a(k)$ *with* $a(1) = 1$, $a(2) = 2$, $a(3) = 4$, $a(4) = 6$.

(e) $(k+1)a(k+2) = 2a(k+1) + (k+3)a(k)$ *with* $a(1) = 1$, $a(2) = 2$.

(f) $(k+2)a(k+3) = (k+3)a(k+2) + (k+2)a(k+1) - (k+3)a(k)$ *with* $a(1) = 1$, $a(2) = 2$, $a(3) = 4$.

9. ***difference equations.*** *The* n^{th} *term of the sequence* $\langle a(k)\rangle_{k=1}^{\infty}$ *which is the solution of* ***any*** *of the following difference equations for all positive integers* k, *where* $\triangle a(k) = a(k+1) - a(k)$ *and* $\triangle^2 a(k) = \triangle a(k+1) - \triangle a(k)$.

(a) $\triangle a(k) = 1, 2, 2, 3, 3, 4, 4, 5, 5, \ldots, \lceil \frac{k+1}{2} \rceil, \ldots$ *and with* $a(1) = 1$. *This difference sequence is like the sequence A004526 of* OEIS [31].

(b) $\triangle^2 a(k) = \begin{cases} 1, & \text{if } k \text{ odd} \\ 0, & \text{if } k \text{ even} \end{cases}$ *with* $a(1) = \triangle a(1) = 1$.

(c) $\triangle a(k+1) + \triangle a(k) = k + 2$ *with* $a(1) = \triangle a(1) = 1$.

(d) $\triangle a(k+2) = \triangle a(k) + 1$ *with* $a(1) = \triangle a(1) = 1, \triangle a(2) = 2$.

(e) $\triangle^2 a(k+1) + \triangle^2 a(k) = 1$ *with* $a(1) = \triangle a(1) = \triangle^2 a(1) = 1$.

(f) $\triangle^3 a(k) + 2\triangle^2 a(k) = 1$ *with* $a(1) = \triangle a(1) = \triangle^2 a(1) = 1$.

10. ***differential equations.***

(a) *The coefficient of* x^{n-1} *in the power series expansion of the solution* $F(x)$ *of the differential equation:* $(1-x^2)\frac{dF}{dx}(x) = 2(1+2x)F(x)$ *with* $F(0) = 1$.

The coefficient of x^n *in the power series expansion of the solution* $F(x)$ *of* ***any*** *of the following differential equations:*

(b) $(1-x^2)\frac{dF}{dx}(x) = (4 + 3x - 2x^2 + x^3)F(x) + 1$ *with* $F(0) = 0$.

(c) $(1-x^2)\frac{d^2F}{dx^2}(x) = (4 + 5x - 2x^2 + x^3)\frac{dF}{dx}(x) + (3 - 4x + 3x^2)F(x)$ *with* $F(0) = 0$, $\frac{dF}{dx}(0) = 1$.

The coefficient of x^{n+1} *in the power series expansion of the solution* $F(x)$ *of* ***any*** *of the following differential equations:*

(d) $(1-x^2)\frac{dF}{dx}(x) = (6 + 2x - 4x^2 + 2x^3)F(x) + 2x$ *with* $F(0) = 0$.

(e) $x(1-x^2)\frac{d^2F}{dx^2}(x) = (1 + 6x + 3x^2 - 4x^3 + 2x^4)\frac{dF}{dx}(x) + (-6 - 4x^2 + 4x^3)F(x)$ *with* $F(0) = 0$ *and* $\frac{d^2F}{d^2x}(0) = 2$. (*or* $\frac{dF}{dx}(-2) = \frac{-4}{27}$, $\frac{dF}{dx}(2) = \frac{28}{9}$)

11. $\underset{k\in\{1,\ldots,n\}}{\text{Max}}\ k \cdot (n-k+1)$.

12. $\max_{\mathfrak{A} \in Part(1..n)} |\mathfrak{A}| \cdot \max_{A \in \mathfrak{A}} |A|$ *where* $Part(1..n)$ *is the collection of set partitions of the set* $\{1, \ldots, n\}$, $|\mathfrak{A}|$ *is the number of blocks, and* $\max_{A \in \mathfrak{A}} |A|$ *is the size of the largest block of partition* $\mathfrak{A}$.

13. $\max_{\alpha \in \mathrm{perm}(n)} i(\alpha) \cdot d(\alpha)$ *where* $\mathrm{perm}(n)$ *is the set of permutations of* $\{1, \ldots, n\}$, $i(\alpha)$ *is the length of the longest increasing subsequence and* $d(\alpha)$ *the longest decreasing subsequence of permutation* α. *See* [30].

14. $\max_{p \in S(n)} \max(p) \cdot \mathrm{len}(p)$ *where* $S(n)$ *is the set of compositions or partitions of* n *(the sequences, with or without regard to order, of positive integers which sum to* n*),* $\max(p)$ *is the size of the largest part, and* $\mathrm{len}(p)$ *is the number of parts of* p. *See chapter 6 of* [29].

15. $\max_{P \in \mathrm{ppart}(n)} \#\mathrm{rows}(P) \cdot \#\mathrm{cols}(P)$ *where* $\mathrm{ppart}(n)$ *is the set of plane partitions or Young tableaux of* n. *See* [8, p.217], [35, p.81], [17] *and* [30].

16. $\max_{G \in \mathrm{graph}(n)} \chi(G) \cdot \chi(\overline{G})$ *where* $\mathrm{graph}(n)$ *is the set of simple graphs on* n *vertices,* $\chi(G)$ *is the chromatic number and* $\overline{G}$ *the complement of graph* G.

17. $\max_{G \in \mathrm{graph}(n)} \omega(G) \cdot \overline{\omega}(G)$ *where* $\mathrm{graph}(n)$ *is the set of simple graphs on* n *vertices,* $\overline{\omega}(G) = \omega(\overline{G})$ *is the independence number and* $\omega(G)$ *is the clique number of graph* G.

18. $\max_{G \in \mathrm{graph}(n)} (1 + \Delta(G)) \cdot \gamma(G)$ *where* $\Delta(G)$ *is the size of the largest degree of the vertices and* $\gamma(G)$ *is the domination number of the simple graph* G. *(*γ *is the smallest size set of vertices of* G*, such that every vertex is in the set or adjacent to it.)*

19. $\max_{u \in \Omega_n} f(u) \cdot g(u)$ *where* $\langle \Omega_k \rangle_{k=1}^{\infty}$ *is a sequence of finite sets and for each positive integer* k*, there are functions* f *and* g *from* Ω_k *to* $\{1, \ldots, k\}$ *such that for all* $u \in \Omega_k$, $f(u) + g(u) \leq k+1$*, and there exist* $w \in \Omega_k$*, such that* $f(w)+g(w) = k+1$ *and* $|f(w)-g(w)| \leq 1$.

    Note that this is a generalization of the above items 11 to 18, which are special cases; see section 2 below.

27. *One more than the sum for* $n\leq m\leq 2n-1$ *of the number of partitions of* m *with two parts minus* $n-1$ *choose* 2 $=1+\sum_{m=n}^{2n-1}\left\lfloor\frac{m-1}{2}\right\rfloor-\binom{n-1}{2}=1+\sum_{m=n}^{2n-1}\left\lfloor\frac{m}{2}\right\rfloor-\left\lfloor\frac{n}{2}\right\rfloor-\binom{n-1}{2}$,

$=1+\sum_{i=0}^{n-1}\left\lfloor\frac{n-1+i}{2}\right\rfloor-\binom{n-1}{2}=1+\sum_{i=0}^{n-1}\left\lceil\frac{n-2+i}{2}\right\rceil-\binom{n-1}{2}$,

$$= \begin{cases} f_f(n)+n, & \text{if } n \text{ odd} \\ f_f(n), & \text{if } n \text{ even} \end{cases} \quad \text{where } f_f(n) = (n+\lfloor n/2 \rfloor)\lfloor n/2 \rfloor - \binom{n}{2},$$

$$= \begin{cases} f_c(n)-n, & \text{if } n \text{ odd} \\ f_c(n), & \text{if } n \text{ even} \end{cases} \quad \text{where } f_c(n) = (n+\lceil n/2 \rceil)\lceil n/2 \rceil - \binom{n}{2}.$$

28. *Turán's number for triangles in a graph on $n+1$ vertices = the maximum number of edges of a graph on $n+1$ vertices which has no triangles* $= \binom{n+1}{2} - \binom{\lfloor \frac{n+1}{2} \rfloor}{2} - \binom{\lfloor \frac{n+2}{2} \rfloor}{2} = \binom{n+1}{2} - \binom{\lceil \frac{n}{2} \rceil}{2} - \binom{\lceil \frac{n+1}{2} \rceil}{2} = \binom{\lfloor \frac{n+2}{2} \rfloor}{2} + \binom{\lfloor \frac{n+3}{2} \rfloor}{2} = \binom{\lceil \frac{n+1}{2} \rceil}{2} + \binom{\lceil \frac{n+2}{2} \rceil}{2} = \binom{\lfloor \frac{n+2}{2} \rfloor}{2} + \binom{\lceil \frac{n+2}{2} \rceil}{2}$.

29. $\max\limits_{u \in [0,1]^{n+1}} \sum\limits_{1 \le i < j \le n+1} |u_i - u_j|$ *where $[0,1]^{n+1}$ is the collection of sequences of real numbers from the interval $[0,1]$ of length $n+1$. This is problem 97 of [4].*

Other expressions. In OEIS [31] for this sequence, there is a reference to probability [16], and in [14] the Encyclopedia of Combinatorial Structures 105 there is a combinatorial structure for this sequence. In [9] this sequence counts orbits of permutation groups. The inverse image of diagonals $(\pm i, \pm i)$ under the spiral function of [20, Exercise 40, p.99] is sequence A002620.

Comment. For all of the expressions in theorem 1.1, it could be argued (or defined) that they are zero for $n = 0$. In the OEIS [31] this sequence is preceded by *two* zeros. One reason for this may be that the lower triangular matrix given by the method of [18] for A002620 has a simpler form when this input sequence has at least two leading zeros. See [27] for more recent work on this method.

2 Antagonistic functions

Two integer functions which satisfy the conditions of item 19 of the main theorem, are antagonistic in the sense that, in general, they are not both too large at the same time.

Definition 2.1 *Let n be a positive integer, Ω a finite set, then f and g are* (*upper*) antagonistic *on Ω of order n if*

1. *f and g are functions from Ω to $\{1, \ldots, n\}$,*
2. *for any $u \in \Omega$, $\quad f(u) + g(u) \le n+1$,*
3. $\max\limits_{u \in \Omega} f(u) \cdot g(u) = \left\lfloor \left(\frac{n+1}{2}\right)^2 \right\rfloor$.

This is related to the upper bound of the Nordhaus-Gaddum inequality [26]; see [15]. Examples of antagonistic functions are in items 11 to 18 of the main theorem. In this paper, only upper antagonistic functions are considered [34].

2.1 Examples which are not antagonistic

A. Let $\Omega_n = \text{graph}(n)$, the simple graphs on n vertices. Let $f(G) = \overline{\omega}(G)$, the independence number of graph G, and $g(G) = 1 + \lfloor \frac{1}{n} \sum_{v=1}^{n} \deg(v) \rfloor$. If $n = 6$, f and g are *not* antagonistic, because the graph G on 6 vertices which is the complement of K_4, has $\overline{\omega}(G) = 4$ and $1 + \lfloor \frac{1}{6} \sum_{v=1}^{6} \deg(v) \rfloor = 1 + \lfloor \frac{18}{6} \rfloor = 4$. Thus $f(G) + g(G) > n + 1$ and the definition fails.

B. Let $\Omega_n = \{1, \ldots, n\}$, $f(i) = i$ and $g(i) = \lceil \frac{n}{i} \rceil$ for $1 \leq i \leq n$. If $5 \leq n$, f and g are *not* antagonistic, since $\underset{i \in \{1..n\}}{\text{Max}} f(i) \cdot g(i) < \left\lfloor \left(\frac{n+1}{2}\right)^2 \right\rfloor$ and the definition fails.

2.2 Properties of antagonistic functions

Proposition 2.2 *Let n be a positive integer, Ω a finite set, f and g functions from Ω to $\{1, \ldots, n\}$, such that for every $u \in \Omega$, $f(u) + g(u) \leq n + 1$, then*
f and g are antagonistic of order n if and only if there is a $w \in \Omega$ such that $\left\lfloor \left(\frac{n+1}{2}\right)^2 \right\rfloor \leq f(w) \cdot g(w)$.

Proof There exists $w \in \Omega$ such that $f(w) \cdot g(w) \geq \left\lfloor \left(\frac{n+1}{2}\right)^2 \right\rfloor$ is the same as $\underset{u \in \Omega}{\text{Max}} f(u) \cdot g(u) \geq \left\lfloor \left(\frac{n+1}{2}\right)^2 \right\rfloor$ and the opposite inequality follows from the AM-GM inequality $ab \leq \left\lfloor \left(\frac{a+b}{2}\right)^2 \right\rfloor$ and the assumption $f(u) + g(u) \leq n + 1$. □

Lemma 2.3 *Let i and j be positive integers, then $|i - j| \leq 1 \iff \left\lfloor \frac{(i+j)^2}{4} \right\rfloor \leq i \cdot j$*

Proof. Let i and j be positive integers, $|i - j| \leq 1 \iff (i - j)^2 \leq 1 \iff (i - j)^2 < 4 \iff (i + j)^2 < 4(ij + 1) \iff \frac{(i+j)^2}{4} - 1 < ij \iff \lfloor \frac{(i+j)^2}{4} \rfloor \leq ij$, for the last implication see [20, p.69]. □

Fact 2.4 *The function $m \mapsto \lfloor \frac{m^2}{4} \rfloor$ on the positive integers is*

1. *strictly increasing and thus is one-to-one, and*
2. *$\lfloor \frac{m^2}{4} \rfloor \leq \lfloor \frac{n^2}{4} \rfloor \Longrightarrow m \leq n$ for all m and n positive integers.*

Lemma 2.5 *Let n be a positive integer, Ω a finite set, f and g functions from Ω to $\{1, \ldots, n\}$, such that for every $u \in \Omega$, $f(u) + g(u) \leq n + 1$, then for every $w \in \Omega$,*
$\left\lfloor \frac{(n+1)^2}{4} \right\rfloor \leq f(w) \cdot g(w)$ *if and only if* $f(w) + g(w) = n + 1$ *and* $|f(w) - g(w)| \leq 1$.

Proof. (⇒ *left part*) By AM-GM, $\left\lfloor \frac{(n+1)^2}{4} \right\rfloor \leq f(w) \cdot g(w) \Rightarrow \left\lfloor \frac{(n+1)^2}{4} \right\rfloor \leq \left\lfloor \frac{(f(w)+g(w))^2}{4} \right\rfloor \Rightarrow n + 1 \leq f(w) + g(w)$ the last by fact 2.4, and since $f(w) + g(w) \leq n + 1$ by assumption, we get $f(w) + g(w) = n + 1$.

(*right part*) $f(w)+g(w) \leq n+1$ and $\left\lfloor \frac{(n+1)^2}{4} \right\rfloor \leq f(w)\cdot g(w) \Rightarrow \left\lfloor \frac{(f(w)+g(w))^2}{4} \right\rfloor \leq f(w)\cdot g(w) \Rightarrow |f(w)-g(w)| \leq 1$ by lemma 2.3. $\square$

Proof. ($\Leftarrow$) (*this is used several times in the following proof of the main theorem*) By lemma 2.3 $|f(w)-g(w)| \leq 1 \Rightarrow \left\lfloor \frac{(f(w)+g(w))^2}{4} \right\rfloor \leq f(w)\cdot g(w)$, but since $f(w)+g(w)=n+1$ we get $\left\lfloor \frac{(n+1)^2}{4} \right\rfloor \leq f(w)\cdot g(w)$. $\square$

In summary we have the following.

Proposition 2.6 (Characterization of antagonistic functions) *Let n be a positive integer, Ω a finite set, and f and g functions from Ω to $\{1,\ldots,n\}$ such that $f(u)+g(u) \leq n+1$ for all $u \in \Omega$, then f and g are antagonistic of order n on Ω if and only if there exists $w \in \Omega$ such that $f(w)+g(w)=n+1$ and $|f(w)-g(w)| \leq 1$.*

Note that, $|f(w)-g(w)| \leq 1$ can be replaced by $|f(w)-g(w)| = \begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases}$ and those $w \in \Omega$ for which the maximum is achieved are exactly those which satisfy the right hand conditions.

Fact 2.7 *Let A and B be finite sets, f a function from A **onto** B, G a mapping from B to $\mathbb{R}$ and for all $a \in A$, let $F(a)=G(f(a))$, then $\underset{a\in A}{\text{Max}}\, F(a) = \underset{b\in B}{\text{Max}}\, G(b)$ and $\underset{a\in A}{\text{Min}}\, F(a) = \underset{b\in B}{\text{Min}}\, G(b)$.*

In items 13 to 17, of the theorem Ω is a complemented lattice. It would be interesting to study those functions f from Ω to $\{1,\ldots,n\}$ such that f and $\overline{f}$ are antagonistic, where $\overline{f}(u)=f(\overline{u})$.

Please send to the author other examples of these functions. (There are more in graph theory, consider upper domination Γ, irredundance IR [12], and CO-irredundance $COIR$ [11] numbers)

We could count those elements which achieve the maximum in items 11 to 18 of the main theorem. Note, we must define when two elements are different.

- For items 14, the count is $1,2,1,2,1,2,1,2,1\cdots = \begin{cases} 1, \text{ if } n \text{ odd} \\ 2, \text{ if } n \text{ even} \end{cases}$ which is sequence A000034.
- For items 11, the count is $1,2,2,6,8,\ldots$
- For item 16, the count is $1,2,2,6,8,\ldots$
- For item 17, the count is $1,2,2,6,7,\ldots$
- For item 18, the count is $1,2,2,5,4,\ldots$

3 Proof of the theorem

Most of the expressions involving floors and ceilings in the theorem may be shown to be equal to item 2 by setting $n = 2k$ and $n = 2k-1$ and manipulating the resulting algebraic expression. Such examples are items 3, 4, 5, 6, 27, and 28. This is how many of these expressions were found.

• $(1 = 2)$ From the pattern of the sequence in item 1, the $2k-1^{th}$ term is k^2 and the $2k^{th}$ term is k^2+k.

• (2) use $\begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases} = \frac{1-(-1)^n}{2}$ for the last equality.

• $(2 = 3)$ If n is odd, $\frac{(n+1)^2}{4} = \left\lfloor \frac{(n+1)^2}{4} \right\rfloor$ since 4 divides $(n+1)^2$ and if n is even $(= 2k)$, then $\frac{(n+1)^2-1}{4} = \frac{(2k+1)^2-1}{4} = k^2+k = \left\lfloor k^2+k+\frac{1}{4} \right\rfloor = \left\lfloor \frac{(2k+1)^2}{4} \right\rfloor = \left\lfloor \frac{(n+1)^2}{4} \right\rfloor$.

• $(2 = 4)$ if n even $(n = 2k)$, then $\left\lfloor \frac{n+1}{2} \right\rfloor \cdot \left\lceil \frac{n+1}{2} \right\rceil = \left\lfloor k+\frac{1}{2} \right\rfloor \cdot \left\lceil k+\frac{1}{2} \right\rceil = k(k+1)$ and if n is odd $(= 2k-1)$, then $\left\lfloor \frac{n+1}{2} \right\rfloor \cdot \left\lceil \frac{n+1}{2} \right\rceil = k^2$.

• (4) The expressions in this item are shown to equal by using $\left\lceil \frac{m}{2} \right\rceil = \left\lfloor \frac{m+1}{2} \right\rfloor$, $\left\lceil \frac{m}{2} \right\rceil - \left\lfloor \frac{m}{2} \right\rfloor = \begin{cases} 1, \text{ if } m \text{ odd} \\ 0, \text{ if } m \text{ even} \end{cases}$ and $\left\lceil \frac{m+1}{2} \right\rceil = \left\lceil \frac{m}{2} \right\rceil + \begin{cases} 0, \text{ if } m \text{ odd} \\ 1, \text{ if } m \text{ even} \end{cases}$ from chapter 3 of [20].

• $(4 = 5)$ item $5 = \sum_{k=1}^{n} \left\lceil \frac{k}{2} \right\rceil = 2\left(\sum_{k=1}^{\lceil n/2 \rceil} k\right) - \begin{cases} \lceil n/2 \rceil, \text{ if } n \text{ odd} \\ 0, \quad \text{if } n \text{ even} \end{cases}$

$= \left\lceil \frac{n}{2} \right\rceil \left(\left\lceil \frac{n}{2} \right\rceil + 1 \right) - \begin{cases} \lceil n/2 \rceil, \text{ if } n \text{ odd} \\ 0, \quad \text{if } n \text{ even} \end{cases} = \left\lceil \frac{n}{2} \right\rceil \left(\left\lceil \frac{n}{2} \right\rceil + \begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases} \right) =$ item 4.

• $(4 = 6)$ Use $m = \left\lfloor \frac{m}{2} \right\rfloor + \left\lceil \frac{m}{2} \right\rceil$.

• (6) In the last line:

For $n = 2m$,

$\sum_{k=\lfloor \frac{n+2}{2} \rfloor}^{n} 2k-n = \sum_{k=m+1}^{2m} 2k-2m = \sum_{i=1}^{m} 2i = \sum_{k=m+1}^{2m} 2k-2m = \sum_{k=\lceil \frac{n+1}{2} \rceil}^{n} 2k-n.$

For $n = 2m-1$,

$\sum_{k=\lfloor \frac{n+2}{2} \rfloor}^{n} 2k-n = \sum_{k=m}^{2m-1} 2k-2m+1 = \sum_{i=1}^{m} 2i-1 = \sum_{k=m}^{2m-1} 2k-2m+1 = \sum_{k=\lceil \frac{n+1}{2} \rceil}^{n} 2k-n.$

• $(7 = (8a, \ldots, 8d))$

Use `rsolve` of Maple V Release 5 (or Maple 7) with generating function option as follows.

```
> 8(a) rsolve({f(n+1)+f(n)=(n+2)*(n+1)/2, f(1)=1}, f,'genfunc'(x)):factor(%);
```

$$-\frac{x}{(-1+x)^3(1+x)}$$

```
> 8(b) rsolve({f(n+2) = f(n)+n+2, f(1)=1,f(2)=2}, f,'genfunc'(x)):factor(%);
```

$$-\frac{x}{(-1+x)^3(1+x)}$$

```
> 8(c) rsolve({f(n+3) =
f(n+2)+f(n+1)-f(n)+1, f(1)=1,f(2)=2,f(3)=4}, f, 'genfunc'(x)):factor(%);
```

$$-\frac{x}{(-1+x)^3(1+x)}$$

```
> 8(d) rsolve({f(n+4) =
2*f(n+3)-2*f(n+1)+f(n), f(1)=1,f(2)=2,f(3)=4,f(4)=6},
f,'genfunc'(x)):factor(%);
```

$$-\frac{x}{(-1+x)^3(1+x)}$$

The generating function option of `rsolve` is only valid for constant coefficients equations.

• (2 = 8) Use `rsolve` of Maple V Release 5 (or Maple 7) as follows.

```
> 8(a) rsolve({f(n+1)+f(n)=(n+2)*(n+1)/2, f(1)=1}, f):simplify(%);
```

$$\frac{1}{8}(-1)^{(n+1)}+\frac{1}{4}n^2+\frac{1}{2}n+\frac{1}{8}$$

```
> 8(b) rsolve({f(n+2) = f(n)+n+2, f(1)=1,f(2)=2}, f):simplify(%);
```

$$\frac{1}{8}(-1)^{(n+1)}+\frac{1}{4}n^2+\frac{1}{2}n+\frac{1}{8}$$

```
> 8(c) rsolve({f(n+3) = f(n+2)+f(n+1)-f(n)+1, f(1)=1,f(2)=2,f(3)=4}, f):
simplify(%);
```

$$\frac{1}{8}(-1)^{(n+1)}+\frac{1}{2}n+\frac{1}{8}+\frac{1}{4}n^2$$

```
> 8(d)
rsolve({f(n+4) = 2*f(n+3)-2*f(n+1)+f(n), f(1)=1,f(2)=2,f(3)=4,f(4)=6},
f):simplify(%);
```

$$\frac{1}{8}(-1)^{(n+1)}+\frac{1}{4}n^2+\frac{1}{2}n+\frac{1}{8}$$

```
> 8(e) rsolve({(n+1)*f(n+2) = 2*f(n+1)+(n+3)*f(n), f(1)=1,f(0)=0},
f):simplify(%);
```

$$\frac{1}{8}(-1)^{(n+1)}+\frac{1}{4}n^2+\frac{1}{2}n+\frac{1}{8}$$

```
> 8(f) rsolve({(n+2)*f(n+3)=
      (n+3)*f(n+2)+(n+2)*f(n+1)-(n+3)*f(n), f(2)=2,f(1) = 1, f(0) = 0},f);
```

$$-\frac{1}{8}(-1)^n+\frac{1}{8}+\frac{1}{2}n+\frac{1}{4}n^2$$

• (8) Using `rectohomrec` from the Maple V Release 5 share package `gfun`, 8a gives 8e, 8b gives 8f and 8c gives 8d.

• (5 = 9*a*) sum of difference, see [24].

• (7 = 9*a*) the generating function of the sequence in item 9a is $\frac{x}{(1-x)(1-x^2)} = \frac{1}{(1-x)}\sum_{k=1}^{\infty} x^{2k-1} = \sum_{k=1}^{\infty}\lceil\frac{k+1}{2}\rceil x^k$.

• (8 = 9) Easy to show 8b=9c and 8c=9d.

• (9) These are shown to be equal by simple manipulations of differences; see [24].

• (7 = 10) Show (using Maple) that the generating function satisfies the differential equation.

• (7 = 10) Use `dsolve` of Maple V Release 5 (or Maple 7) as follows.

```
> 10(a) ode1:=(1-x^2)*diff(F(x),x)=2*(1+2*x)*F(x);
```

$$ode1 := (1-x^2)\,(\tfrac{\partial}{\partial x}\,\mathrm{F}(x)) = 2\,(1+2\,x)\,\mathrm{F}(x)$$

```
> dsolve({ode1,F(0)=1},F(x));
```

$$\mathrm{F}(x) = -\frac{1}{(x+1)\,(x-1)^3}$$

```
> 10(b) ode2:=(1-x^2)*diff(F(x),x)=1+(4+3*x-2*x^2+x^3)*F(x);
```

$$ode2 := (1-x^2)\,(\tfrac{\partial}{\partial x}\,\mathrm{F}(x)) = 1+(4+3\,x-2\,x^2+x^3)\,\mathrm{F}(x)$$

```
> simplify(dsolve({ode2,F(0)=0},F(x)));
```

$$\mathrm{F}(x) = -\frac{x}{(x+1)\,(x-1)^3}$$

```
> 10(c) ode3:=(1-x^2)*diff(F(x),x,x)=(4+5*x-2*x^2+x^3)*diff(F(x),x)+(3-4*x+3*x^2)*F(x);
```

$$ode3 := (1-x^2)\,(\tfrac{\partial^2}{\partial x^2}\,\mathrm{F}(x)) = (4+5\,x-2\,x^2+x^3)\,(\tfrac{\partial}{\partial x}\,\mathrm{F}(x))+(3-4\,x+3\,x^2)\,\mathrm{F}(x)$$

```
> dsolve({ode3,F(0)=0,D(F)(0)=1},F(x));
```

$$\mathrm{F}(x) = -\frac{x}{(x+1)\,(x-1)^3}$$

```
> 10(d) ode4:=(1-x^2)*diff(F(x),x)=2x+(6+2*x-4*x^2+2*x^3)*F(x);
```

$$ode4 := (1-x^2)\,(\tfrac{\partial^2}{\partial x^2}\,\mathrm{F}(x)) = 2x+(6+2\,x-4\,x^2+2\,x^3)\,\mathrm{F}(x)$$

```
> dsolve({ode4,F(0)=0},F(x));
```

$$\mathrm{F}(x) = -\frac{x^2}{(x+1)\,(x-1)^3}$$

```
> 10(e) ode5:=x*(1-x^2)*diff(F(x),x,x)=(1+6*x+3*x^2-4*x^3+2x^4)*F(x)+(-6-4x^2+4x^3)*F(x);
```

$$ode5 := x(1-x^2)\,(\tfrac{\partial^2}{\partial x^2}\,\mathrm{F}(x)) = (1+6\,x+3\,x^2-4\,x^3+2\,x^4)(\tfrac{\partial}{\partial x}\,\mathrm{F}(x))+(-6-4x^2+4x^3)\,\mathrm{F}(x)$$

```
> dsolve({ode5,F(0)=0,D(D(F))(0)=2},F(x));
```

$$\mathrm{F}(x) = -\frac{x^2}{(x+1)\,(x-1)^3}$$

• (1 = 10) `listtodiffeq` from Maple V R5 share package `gfun` was used to get 10a, 10b and 10d.

• (10) Using `diffeqtohomdiffeq` from Maple V Release 5 share package `gfun`, 10b gives 10c and 10d gives 10e.

• (4 = 11) A quadratic $f(x) = ax^2 + bx + c$ with integer coefficients and a negative has its maximum value at $x = \lfloor \frac{-b}{2a} \rfloor$ and $x = \lceil \frac{-b}{2a} \rceil$. So item 11 $= \operatorname{Max}_{k\in\{1..n\}} -k^2 + (n+1)k = (n+1-\lfloor \frac{n+1}{2} \rfloor)\lfloor \frac{n+1}{2} \rfloor = \lceil \frac{n+1}{2} \rceil \lfloor \frac{n+1}{2} \rfloor =$ item 4, since $m - \lfloor \frac{m}{2} \rfloor = \lfloor \frac{m}{2} \rfloor + \begin{cases} 1, \text{ if } n \text{ odd} \\ 0, \text{ if } n \text{ even} \end{cases} = \lceil \frac{m}{2} \rceil$. Similarly for $x = \lceil \frac{n+1}{2} \rceil$.

• (11 = 12) Since item 12 $= \operatorname{Max}_{\mathfrak{A}\in \mathrm{Part}(1..n)} |\mathfrak{A}| \cdot \operatorname{Max}_{A\in\mathfrak{A}} |A| = \operatorname{Max}_{m\in\{1..n\}} m \operatorname{Max}_{\mathfrak{A}\in \mathrm{Part}_m(1..n)} \operatorname{Max}_{A\in\mathfrak{A}} |A| = \operatorname{Max}_{m\in\{1..n\}} m(n-m+1) =$ item 11, where $\mathrm{Part}_m(1..n)$ are the set partitions of $\{1..n\}$ with m blocks.

• (13 = 15) The Robinson-Schensted-Knuth algorithm [8, p.218], [35, p.94] gives a bijection between permutations of $\{1, \ldots, n\}$ and ordered pairs of Young tableaux of n of the same shape, where the number of rows of the tableaux is the length of the longest increasing subsequence of the permutation and the number of columns is length of the longest decreasing

subsequence.

The **RSK** algorithm as used in C. C. Rousseau's *Partitions and q-series in combinatorics* course at the University of Memphis in spring 2000.

Algorithm 3.1: RSK$(n, \langle a_i \rangle_{i=1}^n)$

INPUT: n, a positive integer
INPUT: $(a_i)_{i=1}^n$, a permutation of $\{1..n\}$
OUTPUT: (P, Q), a pair of standard Young tableaux of order n
and both of the same shape

$P[\,,\,] := \emptyset, Q[\,,\,] := \emptyset$ **comment:** these are empty 2D arrays

for $p := 1$ **to** n
do
- $b := a_p$
- $r := 1$
- **while** row r is not empty **and** b is not greater than the last cell in row r of P
  - **do**
    - $c := \text{Min}\{j \mid b \leq P(r, j)\}$
    - swap$(b, P(r, c))$
    - $r := r + 1$
- **comment:** add a new cell at end of row r of P and Q
- $c :=$ 1 + the number of cells in row r
- $P(r, c) := b$
- $Q(r, c) := p$

return (P, Q)

For a partition of n, a, the #rows(shapeRSK(n, a) = the size of longest increasing subsequence of a and #cols(shapeRSK(n, a) = the size of longest decreasing subsequence of a.

The inverse of the **RSK** algorithm.

Algorithm 3.2: `iRSK`$(n, \langle P, Q\rangle)$

INPUT: n, a positive integer
INPUT: (P, Q), a pair of standard Young tableaux of order n
and both of the same shape
OUTPUT: $(a_i)_{i=1}^n$, a permutation of $\{1..n\}$

for $p := n$ **downto** 1
do
- $(r, c) :=$ find the row and column of the value of p in array Q
- $b := P(r, c)$
- delete cell (r, c) of P
- **while** $r \neq 1$ **do**
  - $r := r - 1$
  - **comment:** in row r of P put b in the correct spot and pass back the bumped value as b
  - $c := \text{Max}\{j \mid P(r, j) < b\}$
  - $\text{swap}(b, P(r, c))$
- $a_p := b$

return $((a_i)_{i=1}^n)$

For P, Q StdYoungTab of n with the same shape, then $\text{iRSK}(n, (P, Q))^{-1} = \text{iRSK}(n, (Q, P))$

- (12 = 14) Use fact 2.7.
- (14) use fact 2.7 to show that compositions and partitions of n give the same result.
- (4 = 14) The partitions $(\lfloor \frac{n+1}{2} \rfloor, \underbrace{1, \ldots, 1}_{\lceil \frac{n-1}{2} \rceil \text{ 1's}})$ and $(\lceil \frac{n+1}{2} \rceil, \underbrace{1, \ldots, 1}_{\lfloor \frac{n-1}{2} \rfloor \text{ 1's}})$ are (the only) partitions of n which achieve the maximum value since $\lfloor \frac{n+1}{2} \rfloor + \lceil \frac{n-1}{2} \rceil = n$ and $\lceil \frac{n+1}{2} \rceil + \lfloor \frac{n-1}{2} \rfloor = n$ and they are equal if n is odd. But for the first partition, $\max\cdot\text{len} = \lfloor \frac{n+1}{2} \rfloor \cdot \left(\lceil \frac{n-1}{2} \rceil + 1 \right) =$ item 4, and for the second $\max\cdot\text{len} = \lceil \frac{n+1}{2} \rceil \cdot \left(\lfloor \frac{n-1}{2} \rfloor + 1 \right) =$ item 4.
- (14 = 15) Use fact 2.7.
- (4 = 16) It is known that $\chi(G) + \chi(\overline{G}) \leq n + 1$ for any graph G with n vertices [26], [10, p. 232]. Now if $G = K_{\lceil \frac{n+1}{2} \rceil} \uplus (n - \lceil \frac{n+1}{2} \rceil) K_1$, then $\chi(G) = \chi(K_{\lceil \frac{n+1}{2} \rceil}) = \lceil \frac{n+1}{2} \rceil$ and $\chi(\overline{G}) = \chi(K_n - K_{\lceil \frac{n+1}{2} \rceil}) = n + 1 - \lceil \frac{n+1}{2} \rceil = \lfloor \frac{n+1}{2} \rfloor$. Now proposition 2.6.
- (3 = 17) Let $G = (n - \lceil \frac{n}{2} \rceil) \cdot \mathrm{K}_1 \uplus \mathrm{K}_{\lceil \frac{n}{2} \rceil}$, then $\omega(G) = \lceil \frac{n}{2} \rceil$ and, since $n = \lceil \frac{n}{2} \rceil + \lfloor \frac{n}{2} \rfloor$, $\overline{\omega}(G) = \lfloor \frac{n}{2} \rfloor + 1$, so $\overline{\omega}(G) - \omega(G) = 1 - (\lceil \frac{n}{2} \rceil - \lfloor \frac{n}{2} \rfloor) = \begin{cases} 0, \text{ if } n \text{ odd} \\ 1, \text{ if } n \text{ even} \end{cases}$. We also have $\overline{\omega}(H) + \omega(H) \leq n + 1$ for every $H \in \text{graph}(n)$, so use proposition 2.6.
- (4 = 18) It is known that $1 + \Delta(G) + \gamma(\overline{G}) \leq n + 1$ for any graph G with n vertices [5, p. 304]. Let $G = \lceil \frac{n-1}{2} \rceil \cdot \mathrm{K}_1 \uplus \mathrm{K}_{1, \lfloor \frac{n-1}{2} \rfloor}$, then $1 + \Delta(G) = 1 + \lfloor \frac{n-1}{2} \rfloor = \lfloor \frac{n+1}{2} \rfloor$ and $\gamma(G) = 1 + \lceil \frac{n-1}{2} \rceil = \lceil \frac{n+1}{2} \rceil$. note that $|V(G)| = \lceil \frac{n-1}{2} \rceil + \lfloor \frac{n-1}{2} \rfloor + 1 = n$.
- (3 = 19) See proposition 2.6.

• (5 = 20) The number of graphs with only m loops on two vertices is equal to the number of partitions of m with at most two parts ($= \lfloor \frac{m+2}{2} \rfloor$). Of the $n-1$ edges if $k \in \{1, \ldots, n-1\}$ are between vertices, there are then $\lfloor \frac{n-1-k+2}{2} \rfloor$ graphs with the remaining edges. Hence the total number of graphs is $\sum_{k=0}^{n-1} \lfloor \frac{n-1-k+2}{2} \rfloor = \sum_{k=0}^{n-1} \lfloor \frac{k+2}{2} \rfloor$ which is item 5.

• (6 = 22) From the following table of the triangles with largest side n, we see that the total number of triangles is $\sum_{k=0}^{\lfloor \frac{n-1}{2} \rfloor} (n-2k)$ which is item 6.

n	sides of triangle
1	111
2	222 221
3	333 332 331 , 322
4	444 443 442 441 , 433 432
5	555 554 553 552 551 , 544 543 542 , 533

Note the strict triangular inequality will be satisfied for integer sided triangles.

• (1 = 22) See [22].

• (9c = 23) Let $k = 1$ in 23, see [2].

• (9a = 24) From the definition of the Losanitsch number following the table of values of $L(r, c)$, we have $L(3, c+1) - L(3, c) = L(2, c+1) = 1, 2, 2, 3, 3, 4, 4, \ldots$ and $L(2, 1) = 1$, which is item 9a.

• (25 = 26) $a_{n,k} = \begin{cases} 1, & \text{if } k = 1 \\ |\{U \in A_n | \min(U) = k-1\}|, & \text{if } k \neq 1 \end{cases}$, where $a_{n,k}$ is the values of the array in item 26, and A_n is as in item 25. (this is how the array in item 26 was found)

• (2 = 26) If n is even item $26 = 2\sum_{k=1}^{\frac{n}{2}} k = \frac{n}{2}(\frac{n}{2}+1) =$ item 2. If n is odd item $26 = 2\sum_{k=1}^{\frac{n-1}{2}} k + \frac{n+1}{2} = \frac{n-1}{2}(\frac{n-1}{2}+1) + \frac{n+1}{2} =$ item 2.

• (2 = 27) Let $n = 2k$ and $= 2k-1$. See chapter 6 of [29] for partitions.

• (28) use: if $n = 2k$ then $\lfloor \frac{n+1}{2} \rfloor = \lceil \frac{n}{2} \rceil = k$, $\lfloor \frac{n+2}{2} \rfloor = \lceil \frac{n+1}{2} \rceil = k+1$, and $\lfloor \frac{n+3}{2} \rfloor = \lceil \frac{n+2}{2} \rceil = k+1$.

if $n = 2k+1$ then $\lfloor \frac{n+1}{2} \rfloor = \lceil \frac{n}{2} \rceil = k+1$, $\lfloor \frac{n+2}{2} \rfloor = \lceil \frac{n+1}{2} \rceil = k+1$, and $\lfloor \frac{n+3}{2} \rfloor = \lceil \frac{n+2}{2} \rceil = k+2$.

• (4 = 28) Let $s = 3$ and $m = n+1$ in Turán's theorem.

Every graph on m vertices not containing a complete graph of s vertices, K_s, has at most $ex(m; K_s^{(2)})$ vertices.

Proposition 3.1 (Turán[1, 25]) *Let $2 \leq m, s$ be positive integers, then the following are equal.*

1. $\binom{m}{2} - \sum_{i=0}^{s-2} \binom{\lfloor \frac{m+i}{s-1} \rfloor}{2}$, *see* [6, p.294],[7, p.54]
2. $\sum_{0 \leq i < j < s-1} \left\lfloor \frac{m+i}{s-1} \right\rfloor \cdot \left\lfloor \frac{m+j}{s-1} \right\rfloor$, *see* [6, 294],[19, p.1234]
3. $\frac{(s-2)(m^2-k^2)}{2(s-1)} + \binom{k}{2}$ *where* $k = \mod(m, s-1) = m - (s-1)\lfloor \frac{m}{s-1} \rfloor$, *see* [21, p.18]

4. $ex(m; K_s^{(2)})$:= *the maximum number of* 2*-sets* (*edges*) *of* $\{1, \ldots, m\}$ *which have no* s *cliques.*

	$ex(m; K_s^{(2)})$														sequence
$s \backslash m$	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
2	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
3	1	2	4	6	9	12	16	20	25	30	36	42	49	56	**A002620**
4	↓	3	5	8	12	16	21	27	33	40	48	56	65	75	A000212
5		↓	6	9	13	18	24	30	37	45	54	63	73	84	A033436
6			↓	10	14	19	25	32	40	48	57	67	78	90	A033437
7				↓	15	20	26	33	41	50	60	70	81	93	
8					↓	21	27	34	42	51	61	72	84	96	
9						↓	28	35	43	52	62	73	85	98	

The numbers in the diagonal sequence $1, 3, 6, 10, 15, 21, 28, 36, \ldots$ are the triangle numbers, sequence A000217 $= \lim_{s \to \infty} ex(m; K_s^{(2)})$.

• (6 = 29) See proof in [4, Problem 97].

End of proof of the theorem. ☺

Redundancy in the above illustrates different methods. Some of these methods may suggest ways to analyze other sequences, see [33, Ch.2].

Using $\sum_{k=n}^{2n-1} \begin{cases} 0, \text{ if } k \text{ odd} \\ 1, \text{ if } k \text{ even} \end{cases} = \lfloor \frac{n}{2} \rfloor$, $p_2(k) = p_2^*(k) + \begin{cases} 0, \text{ if } k \text{ odd} \\ 1, \text{ if } k \text{ even} \end{cases}$ and 25 and 27 of the theorem we have.

Corollary 3.2 *For* n *a positive integer.*

$$\sum_{k=0}^{n-1} (p_2^*(n+k) - p_2^*(\max \leq n, n+k)) \quad = \quad \sum_{k=0}^{n-1} p_2^*(\max > n, n+k) \quad = \quad \binom{n-1}{2}$$

where $p_2^*(m) =$ *the number of partitions of* m *with two* distinct *parts, and* $p_2^*(\max > n, m) =$ *the number of partitions of* m *with two* distinct *parts, the largest part greater than* n. *See* [3, Ch.12,13,14],[28],[29, Ch.6] *for partitions.*

Objects Counted by the Central Delannoy Numbers

Robert A. Sulanke
Department of Mathematics
Boise State University
Boise, Idaho 83725
USA

Abstract: The central Delannoy numbers, d_n_{n >=0} = 1,3,13,63,321, 1683, 8989, 48639, ... (A001850 of {\it The On-Line Encyclopedia of Integer Sequences}) will be defined so that d_n counts the lattice paths running from (0,0) to *(n,n)* that use the steps (1,0), (0,1), and (1,1). In a recreational spirit we give a collection of 29 configurations that these numbers count.

OBJECTS COUNTED BY THE CENTRAL DELANNOY NUMBERS

ROBERT A. SULANKE

Abstract. The central Delannoy numbers, $(d_n)_{n\geq 0} = 1, 3, 13, 63, 321, 1683, 8989, 48639, \ldots$ (A001850 of *The On-Line Encyclopedia of Integer Sequences*) will be defined so that d_n counts the lattice paths running from $(0,0)$ to (n,n) that use the steps $(1,0)$, $(0,1)$, and $(1,1)$. In a recreational spirit we give a collection of 29 configurations that these numbers count.

1. Introduction

In the late nineteenth century, Henri Delannoy [4] introduced what we now call the *Delannoy array.* For integers i and j, we define this array $d_{i,j}$ to satisfy

$$d_{i,j} = d_{i-1,j} + d_{i,j-1} + d_{i-1,j-1}$$

with the conditions $d_{0,0} = 1$ and $d_{i,j} = 0$ if $i < 0$ or $j < 0$. The members of the sequence $(d_i)_{i\geq 0} := (d_{i,i})_{i\geq 0} = 1, 3, 13, 63, 321, 1683, 8989, 48639, \ldots$ (A001850 of Sloane [15]), are known as the (central) *Delannoy numbers.*

$d_{i,j} :=$

$i \setminus j$	0	1	2	3	4
0	1	1	1	1	1
1	1	3	5	7	9
2	1	5	13	25	41
3	1	7	25	63	129
4	1	9	41	129	321

In Section 3 we will show that the generating function for the central Delannoy numbers satisfies

$$\sum_{i\geq 0} d_i z^i = \frac{1}{\sqrt{1-6z+z^2}}. \tag{1}$$

An alternative derivation of this is given by Stanley [16, Sect. 6.3]. These numbers satisfy the recurrence,

$$(n+2)d_{n+2} = 3(2n+3)d_{n+1} - (n+1)d_n. \tag{2}$$

subject to $d_0 = 1$ and $d_1 = 3$, as shown, e.g., by Stanley [16, Sect. 6.4] and the author [18].

We refer the question, "Why Delannoy numbers?", to the survey on the life and works of Delannoy written by Banderier and Schwer [1]. While the (central) Delannoy numbers are known through the books of Comtet [3] and Stanley [16], only a few examples of objects enumerated by these numbers have been found in the literature. These examples will appear and be referenced in the following sections.

After Delannoy's introduction of the numbers, essentially as counting unrestricted paths that use the steps $(0,1)$, $(1,0)$, and $(1,1)$, they appear again in 1952, when Lawden [8], without citing Delannoy, found them to be the values of the Legendre polynomials with argument equaling 3. However, the definition of the Legendre polynomials does not appear to foster any combinatorial interpretation leading to enumeration. See also Moser and Zayachkowski [9].

In the following section we give a catalog of 29 configurations counted by the (central) Delannoy numbers, ordered primarily as they were collected. In keeping with Delannoy's interest in recreational mathematics, this catalog is intended to constitute exercises inviting bijective, recursive, and generating functional proofs that the Delannoy numbers do indeed count the configurations. Each example is accompanied by an illustration of a set of configurations corresponding to $d_2 = 13$. Section 3 contains intentionally incomplete notes regarding some bijective and generating functional verifications for the examples.

The collector wishes to thank Cyril Banderier, Emeric Deutsch, Enrica Duchi, Ira Gessel, Sylviane Schwer, Lou Shapiro, and Renzo Sprugnoli for their contribution to this project. He also appreciates the referee's generous critique.

2. A catalog of configurations

In the integer plane, we will take lattice paths to be represented as concatenations of the directed steps belonging to various specified sets. When the steps are weighted, the weight of a path is the product of the weights of its steps, and the weight of a path set is the sum of the weights of its paths. As noted in the remark following Example 3, the independent coloring of substructures on paths is equivalent to weighting. Throughout, we will denote the diagonal up and down steps as $U := (1,1)$ and $D := (1,-1)$.

Example 1. A classic example is the set of paths from $(0,0)$ to $(2n,0)$ using the steps U, D, and $(2,0)$. For the "tilted" version consider the path from $(0,0)$ to (n,n) using the steps $(0,1)$, $(1,0)$, and $(1,1)$. From this path model one can obtain a combinatorial proof that, for $n \geq 0$,

$$d_n = \sum_{k=0}^{n} \binom{n}{k} \binom{n+k}{k}. \tag{3}$$

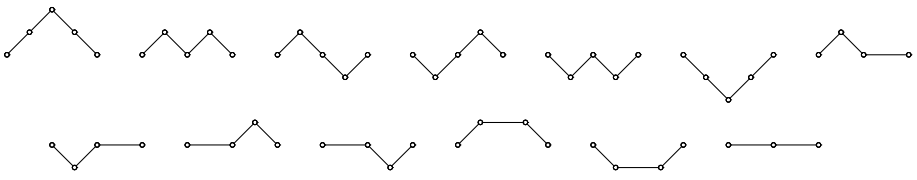

Figure 1. The $d_2 = 13$ unrestricted paths from $(0,0)$ to $(2n,0)$ using the steps U, D, and $(2,0)$.

Example 2. The Delannoy number d_n is the weight of the set of paths from $(0,0)$ to $(n,0)$ using the steps U_2, D, and $(1,0)_3$, where the up step U_2 and the horizontal step $(1,0)_3$ have weights 2 and 3, respectively.

Alternatively, d_n counts the paths from $(0,0)$ to $(n,0)$ using the steps U, D, and $(1,0)$, where the U steps are independently colored blue or red and the $(1,0)$ steps are independently colored blue, red, or green. See the remark following Example 3.

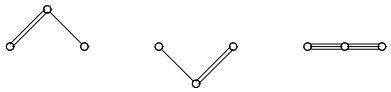

FIGURE 2. Here $2+2+3\cdot 3 = d_2$

Example 3. Using the steps U and D, we find d_n to be the weighted sum of the paths from $(0,0)$ to $(2n,0)$ where within each path the right-hand turns, or *peaks*, have weight 2. Consequently, one can obtain a combinatorial proof that, for $n \geq 0$,

$$\sum_{i=0}^{n} \binom{n}{i}^2 2^i = d_n. \tag{4}$$

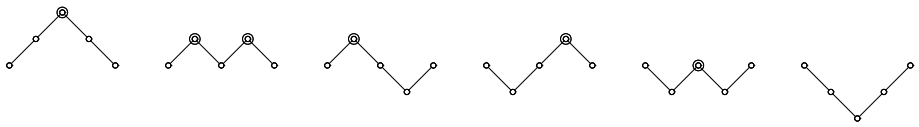

FIGURE 3. The sum of the weights of the paths is $2+4+2+2+2+1 = d_2$.

Remark: Often, as in Examples 3, we will consider paths with substructures – such as peaks, double ascents, etc. – which make a multiplicative contribution of 2 to the weight of each path. Other such examples include 4, 5, 14, 20, 21, 24, 25, 26, and 27. If momentarily the weights of the substructures is reduced to 1, then the weight of a set of such paths becomes a cardinality, namely the central binomial coefficient, $\binom{2n}{n}$. Indeed, in the figures for the above named examples, there will be $\binom{4}{2} = 6$ shapes in each illustration. However, when the substructures have weight 2, the weight of the set of such paths is a Delannoy number, which in turn is the cardinality of the paths of same shapes on which the substructures are independently colored Blue or Red. In this catalog we will usually omit versions of examples with Blue-Red substructures, which would yield 13 shapes instead of 6 shapes in the relevant illustrations.

Example 4. Using the steps U and D, we find that d_n is the sum of the weights of the paths from $(0,0)$ to $(2n+1,1)$ that begin with an up step and where the intermediate vertices of double ascents have weight 2.

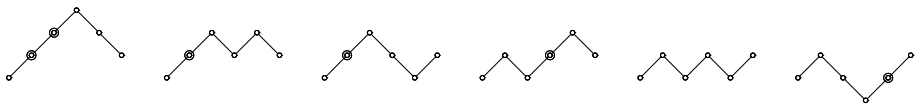

FIGURE 4. The sum of the weights of the paths is $4+2+2+2+1+2=d_2$.

Example 5. Using the steps U and D, we find that d_n is the weighted sum over the paths from $(0,0)$ to $(2n,0)$ where each U step which is oddly positioned along its path has weight 2.

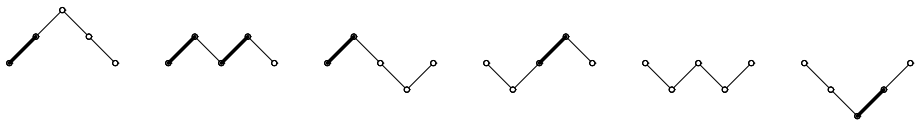

FIGURE 5. The sum over the weights of the paths is $2+4+2+2+1+2=d_2$.

Example 6. The product $2^{n-1}d_n$ counts the set of all paths from $(0,0)$ to (n,n) with steps of the form (x,y) where x and y are nonnegative integers, not both 0.

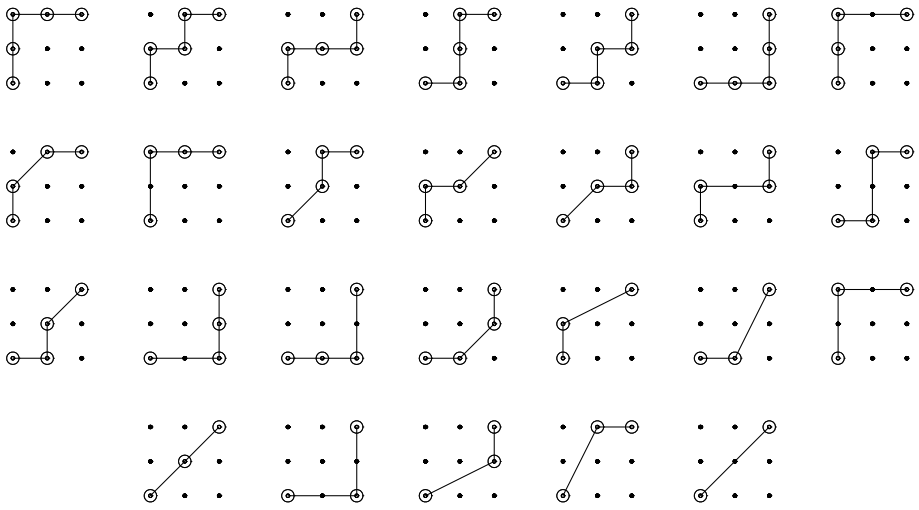

FIGURE 6. Here $2^{n-1}d_n = 2 \cdot 13$, for $n=2$.

Example 7. Using the steps U_2, D, and $(2,0)_{-1}$ where the up step and the horizontal step have weights of 2 and -1, respectively, d_n is the sum of the weights of the paths running from $(0,0)$ to $(2n,0)$.

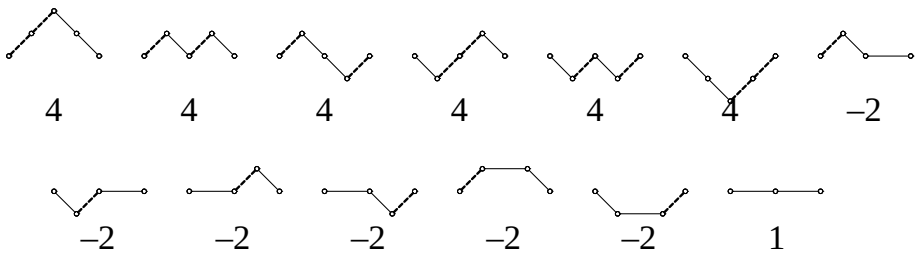

FIGURE 7. The sum over the paths is 13.

Example 8. Here we consider a *second moment* for a path set. Using the steps U, D, and $(2,0)$, for the elevated (Schröder) paths running from $(0,0)$ to $(2n+2,0)$, we find that d_n is the sum, over its paths, of the average of the positive squared heights of the lattice points traced by each path.

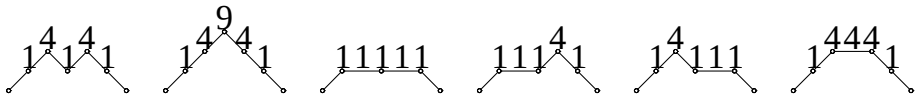

FIGURE 8. Within each path the squared heights are additive. $\frac{11}{5}+\frac{19}{5}+\frac{5}{5}+\frac{8}{5}+\frac{8}{5}+\frac{14}{5}=\frac{65}{5}=d_2$.

Example 9. We consider another *second moment*. Consider the elevated Schröder paths running from $(0,0)$ to $(2n+2,0)$ where within each path the noninitial up step and the horizontal steps have weights 2 and -1, respectively. Here d_n is the sum of the weighted average of the positive squared heights of the lattice points traced by each path.

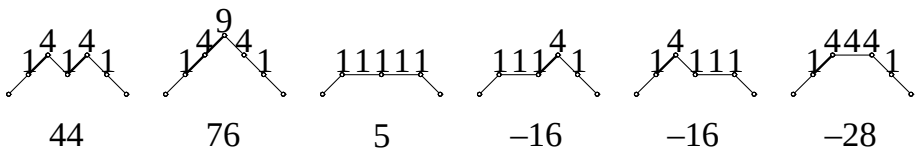

FIGURE 9. The sum over the paths is $\frac{44}{5}+\frac{76}{5}+\frac{5}{5}+\frac{(-16)}{5}+\frac{(-16)}{5}+\frac{(-28)}{5}=d_2$.

Example 10. We consider one more *second moment*. Take the elevated paths running from $(0,0)$ to $(n+2,0)$ using the steps U, D, and $(1,0)$, where the noninitial U steps have weight 2 and the unit horizontal steps have weight 3. Here d_n is the sum of the weighted average of the positive squared heights of the lattice points traced by each path.

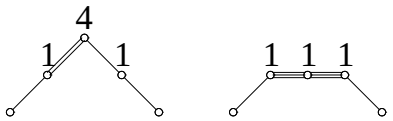

FIGURE 10. The sum over the paths is $\frac{2(1+4+1)}{3} + \frac{3\cdot3(1+1+1)}{3} = d_2$.

Example 11. Here we will define a *zebra* to be a parallelogram polyomino whose noninitial columns are either white or gray. For any zebra, its *average diagonal thickness squared* will be the average of the squares of the number of unit cells along each –45 degree diagonal passing through the center of the cells. The sum, over all zebras of a fixed perimeter $2n+4$, of the average diagonal thickness squared is the Delannoy number d_n.

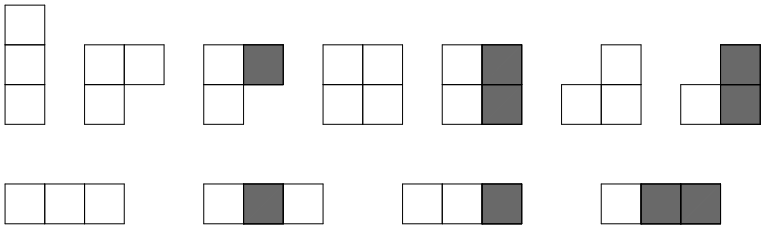

FIGURE 11. The sum of the average diagonal thickness squared is $\frac{1+1+1}{3} + \frac{2(1+1+1)}{3} + \frac{2(1+4+1)}{3} + \frac{2(1+1+1)}{3} + \frac{4(1+1+1)}{3} = d_2$.

Example 12. The number d_n counts the domino tilings of the Aztec diamond of width $2n$ having an additional center row.

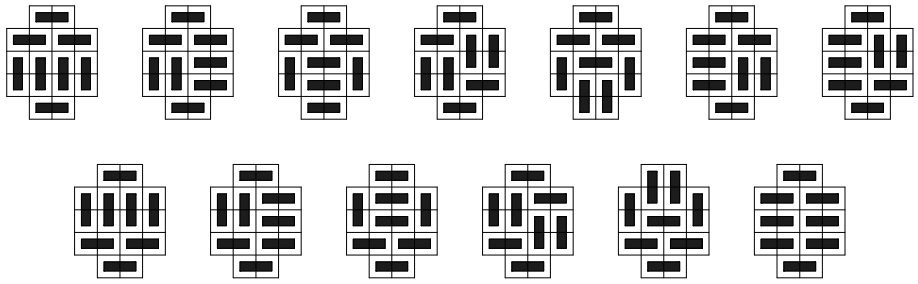

FIGURE 12. d_2 tilings.

Example 13. Consider counting matchings in the comb graph. For a comb with $2n$ teeth, there are d_n ways to have an n-set of non-adjacent edges.

FIGURE 13. The d_2 2-matchings in the comb with $2 \cdot 2$ teeth.

Example 14. In a lattice path using the steps U and D, a *long*, is a maximal subpath having at least two steps, all of the same type. The number d_n is the weighted sum over the paths running from $(0, 0)$ to $(2n + 1, 1)$ which begin with a U step and whose nonfinal longs have the weight 2.

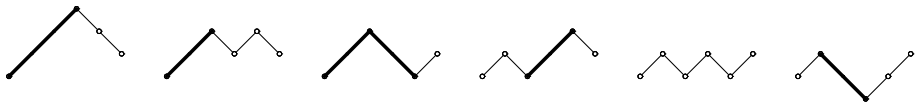

FIGURE 14. The sum of the weights of the paths is $2 + 2 + 4 + 2 + 1 + 2 = d_2$.

Example 15. Consider the walks that begin at the origin and use the unit steps: east (E), west (W), and north (N). If these walks never start with W and are self-avoiding, that is, E and W are nonadjacent, then d_n counts the walks with $2n$ steps and final height n.

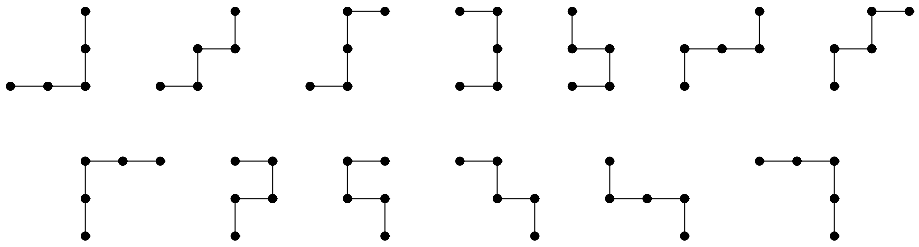

FIGURE 15. d_2 walks.

Example 16. The number d_n counts the ways to distribute n white and n black balls into r labeled urns where r takes on the values from n to $2n$ and where each urn is nonempty and does not contain more than one ball of each color. (The balls are unlabeled and are ordered so that white precedes black when two are present in an urn.)

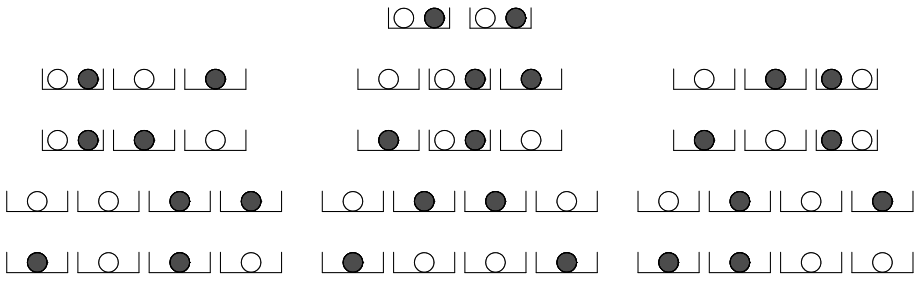

FIGURE 16. d_2 balls-in-urns distributions.

Example 17. The number d_n counts the words from the alphabet { a,b, {a,b} } where the total occurrences of a and b in each word is n.

$$\{a,b\}\{a,b\},\ \{a,b\}ab,\ \{a,b\}ba,\ a\{a,b\}b,\ b\{a,b\}a,\ ab\{a,b\},\ ba\{a,b\},$$
$$aabb,\ abab,\ abba,\ baab,\ baba,\ bbaa$$

FIGURE 17. d_2 words.

Example 18. In $\mathbb{Z}^n$, d_n counts the n-dimensional lattice points inside or on the hyperoctahedron with vertices on the axes located a distance n from the origin. More specifically, for $z = (z_1, \ldots, z_n) \in \mathbb{R}^n$, let $||z||_1$ denote the norm $\sum_{i=1}^{n} |z_i|$. Then $d_n = |\{y \in \mathbb{Z}^n : ||y||_1 \leq n\}|$.

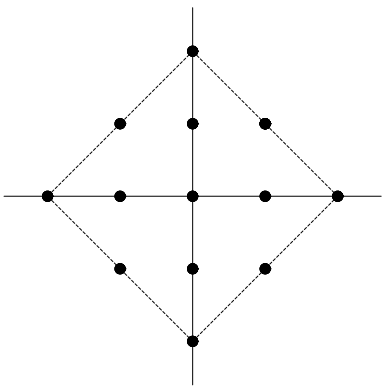

FIGURE 18. For $n = 2$, $d_2 = 13$ is the number of lattice points inside the square region $\{(x, y) : |x| + |y| \leq 2\}$.

Example 19. The number d_n counts the set of paths using the three steps types, U, D, and $(2,0)$, running from $(0,0)$ to the line $x = 2n$, and remaining weakly above the x-axis.

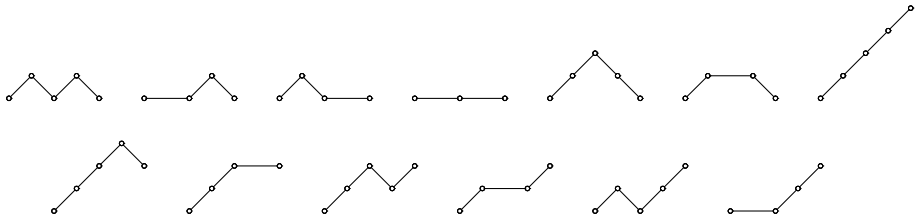

FIGURE 19. The paths running from $(0,0)$ to the line $x = 4$ and remaining weakly above the x-axis.

Example 20. For the steps U and D, d_n is the weighted sum of the paths running from $(0,0)$ to the line $x = 2n$ and remaining weakly above the x-axis, where within each path the right-hand turns have weight 2.

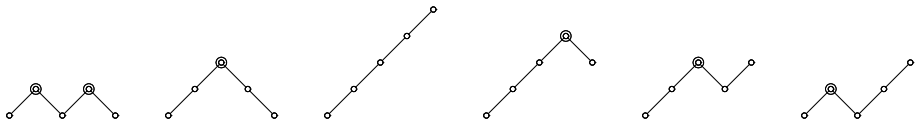

FIGURE 20. The sum of the weights of the paths is $4 + 2 + 1 + 2 + 2 + 2 = d_2$.

Example 21. For the steps U and D, d_n is the weighted sum of the paths running from $(0,0)$ to the line $x = 2n$ and remaining weakly above the x-axis, where within each path each *long* has weight 2. Here a *long* is a maximal subpath of the same step type of length exceeding one.

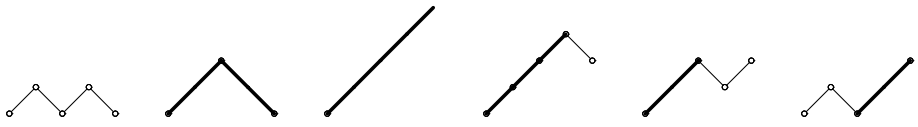

FIGURE 21. The sum of the weights of the paths is $1 + 4 + 2 + 2 + 2 + 2 = d_2$.

Example 22. Consider the known array extending the large Schröder numbers: namely, for integers i and j, we define this array $r_{i,j}$ to satisfy

$$r_{i,j} = r_{i-1,j} + r_{i,j-1} + r_{i-1,j-1}$$

with the conditions $r_{0,0} = 1$ and $r_{i,j} = 0$ if $j < 0$ or $i < j$. The members of the sequence $(r_i)_{i\geq 0} := (r_{i,i})_{i\geq 0} = 1, 2, 6, 22, 90\ldots$ are known as the large Schröder numbers. The central Delannoy number d_n is the sum of the $2n+1$-st diagonal, that is $d_n = \sum_i r_{i,2n-i}$.

$r_{i,j} :=$

$i \setminus j$	0	1	2	3	4
0	1	0	0	0	0
1	1	2	0	0	0
2	1	4	$\boxed{6}$	0	0
3	1	$\boxed{6}$	16	22	0
4	$\boxed{1}$	8	30	68	90

FIGURE 22. An array of the extended large Schröder numbers. Here $\boxed{1} + \boxed{6} + \boxed{6} = d_2$.

Example 23. Let $T(n)$ denote the set of plane trees with $2n+1$ edges, with roots of odd degree, with the non-root vertices having degree 1 (for the leaves), 2, or 3, and with an even number of vertices of degree two between any two vertices of odd degree.

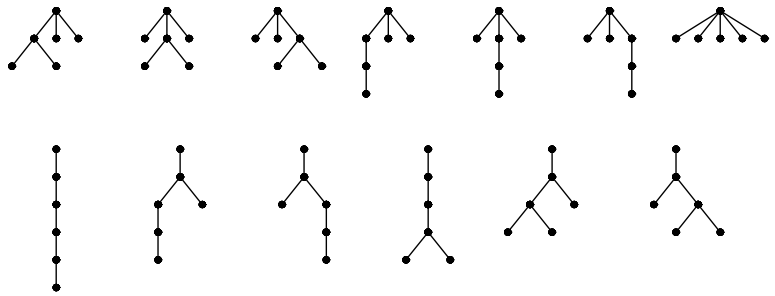

FIGURE 23. The specified trees counted by d_2.

Example 24. A *high peak* is the intermediate vertex of a UD pair with ordinate exceeding 1. Let $\mathcal{P}(n,k)$ denote the set of paths using the steps U and D, running from $(0,0)$ to $(n,0)$, remaining weakly above the x-axis, intersecting the x-axis k times, and having high peaks of weight 2. Then the Delannoy number counts a union of sets:

$$d_n = \left| \bigcup_{i=1}^{n+1} \mathcal{P}(2n+2i, 2i) \right|.$$

FIGURE 24. $4+2+2+2+2+1=d_2$.

Example 25. A *double ascent* (or *double rise*) is just a consecutive UU pair. Let $\mathcal{P}(n,k)$ denote the set of paths using the steps U and D, running from $(0,0)$ to $(n,0)$, remaining weakly above the x-axis, intersecting the x-axis k times, and having double ascents of weight 2. Then the Delannoy number counts a union of sets:

$$d_n = \left| \bigcup_{i=1}^{n+1} \mathcal{P}(2n+2i, 2i) \right|.$$

FIGURE 25. $2+4+2+2+2+1=d_2$.

Example 26. Let $\mathcal{P}(n,k)$ denote the set of paths using the steps U and D, running from $(0,0)$ to $(n,0)$, remaining weakly above the x-axis, intersecting the x-axis k times, and evenly positioned ascents of weight 2. Then the Delannoy number counts a union of sets:

$$d_n = \left| \bigcup_{i=1}^{n+1} \mathcal{P}(2n+2i, 2i) \right|.$$

FIGURE 26. $4+2+2+2+2+1=d_2$.

Example 27. On a path using the steps U and D, a *restricted long* is a maximal subpath of a single step type having length exceeding 1, except when the subpath ends at the x-axis, in which case the length of the subpath must exceed 2. Let $\mathcal{P}(n,k)$ denote the set of paths using the steps U and D, running from $(0,0)$ to $(n,0)$, remaining weakly above the x-axis, intersecting the x-axis k times and having restricted longs of weight 2. Then the Delannoy number counts a union of sets:

$$d_n = \left| \bigcup_{i=1}^{n+1} \mathcal{P}(2n+2i, 2i) \right|.$$

FIGURE 27. $2+4+2+2+2+1=d_2$.

Example 28. The central Delannoy number d_n counts the matrices with 2 rows and entries 0 or 1 such that there are exactly n 1's in each row and at least one 1 in each column.

$$\begin{bmatrix}1&1\\1&1\end{bmatrix}\quad\begin{bmatrix}1&1&0\\1&0&1\end{bmatrix}\quad\begin{bmatrix}1&0&1\\1&1&0\end{bmatrix}\quad\begin{bmatrix}1&1&0\\0&1&1\end{bmatrix}\quad\begin{bmatrix}0&1&1\\1&1&0\end{bmatrix}$$

$$\begin{bmatrix}1&0&1\\0&1&1\end{bmatrix}\quad\begin{bmatrix}0&1&1\\1&0&1\end{bmatrix}\quad\begin{bmatrix}1&1&0&0\\0&0&1&1\end{bmatrix}\quad\begin{bmatrix}1&0&1&0\\0&1&0&1\end{bmatrix}$$

$$\begin{bmatrix}1&0&0&1\\0&1&1&0\end{bmatrix}\quad\begin{bmatrix}0&1&1&0\\1&0&0&1\end{bmatrix}\quad\begin{bmatrix}0&1&0&1\\1&0&1&0\end{bmatrix}\quad\begin{bmatrix}0&0&1&1\\1&1&0&0\end{bmatrix}$$

FIGURE 28. There are d_2 such matrices.

Example 29. The product $2^{n-1}d_n$ counts the matrices having two rows and nonnegative integer entries where each row sum is n and each column has at least one positive entry.

$$\begin{bmatrix}2\\2\end{bmatrix}\quad\begin{bmatrix}2&0\\0&2\end{bmatrix}\quad\begin{bmatrix}0&2\\2&0\end{bmatrix}\quad\begin{bmatrix}2&0&0\\0&1&1\end{bmatrix}\quad\begin{bmatrix}0&2&0\\1&0&1\end{bmatrix}$$

$$\begin{bmatrix}0&0&2\\1&1&0\end{bmatrix}\quad\begin{bmatrix}0&1&1\\2&0&0\end{bmatrix}\quad\begin{bmatrix}1&0&1\\0&2&0\end{bmatrix}\quad\begin{bmatrix}1&1&0\\0&0&2\end{bmatrix}$$

$$\begin{bmatrix}2&0\\1&1\end{bmatrix}\quad\begin{bmatrix}0&2\\1&1\end{bmatrix}\quad\begin{bmatrix}1&1\\2&0\end{bmatrix}\quad\begin{bmatrix}1&1\\0&2\end{bmatrix}$$

FIGURE 29. $2\cdot d_2$ counts the set formed by these matrices and those of Figure 28.

3. NOTES REGARDING VERIFICATIONS

Before reviewing the above examples, let us look at a mildly general lattice path model. For fixed positive integer h, we will allow the three steps U_t, D, and $(h,0)_s$ which are weighted by t, 1, and s, respectively. For $n\geq 0$, let $\mathcal{U}(n)$ denote the set of all *unrestricted* paths running from $(0,0)$ to $(n,0)$, and let $\mathcal{C}(n)$ denote the set of paths in $\mathcal{U}(n)$ *constrained* never to pass beneath the horizontal axis. We will use a well-known decomposition of path sets to derive formulas for the generating functions $c(z):=\sum_{n\geq 0}|\mathcal{C}(n)|z^n$ and $u(z):=\sum_{n\geq 0}|\mathcal{U}(n)|z^n$.

Since each path of $\mathcal{C}(n)$ must either (i) have zero length, (ii) start with an $(h,0)$ step followed by a constrained path, or (iii) start with an U step followed by the translation of a constrained path, then by a D, and finally by another constrained path we have

$$c(z) = 1 + sz^h c(z) + tz^2 c(z)^2.$$

Since every path in $\mathcal{U}(n)$ either (i) has zero length, (ii) begins with an $(h,0)$ step followed by an unrestricted path, or (iii) begins with U (or with D) followed by a constrained path (or its reflection) which returns to the horizontal axis for the first time and then is followed by an unrestricted path,

$$u(z) = 1 + sz^h u(z) + 2tz^2 c(z)u(z)$$

Solving these two equations simultaneously yields

$$u(z) = \frac{1}{\sqrt{(1-sz^h)^2 - 4tz^2}} = \frac{1}{\sqrt{1 - 2sz^h + s^2z^{2h} - 4tz^2}}.$$

If this formula is to agree essentially with the formula of (1), then either $h = 1$ or $h = 2$. If $h = 1$, then $u(z) = 1/\sqrt{1 - 2sz + (s^2 - 4t)z^2}$, and it must be that $s = 3$ and $t = 2$. On the other hand, if $h = 2$, then $u(z) = 1/\sqrt{1 - (2s + 4t)z^2 + s^2z^4}$, and thus either $s = t = 1$ or $s = -1$ and $t = 2$.

We number the subsequent Notes to agree with the numbering of the examples of Section 2. Since the examples may serve as exercises and since they are ordered as collected, these notes may appear mildly haphazard.

Note 1 The introductory discussion of this section gives the generating function for Example 1. One can find an alternate derivation of the generating function and a recurrence in [20, Sect. 6]. Equation (3) can be obtained by considering all possible choices for the steps in the paths leading to $(n,0)$.

Note 2 That the Delannoy numbers count Example 2 follows from the initial discussion of this section. In Note 5 we will see how Example 2 is bijectively related to Example 1 via Examples 3 and 5.

Note 3 Replicate the paths from $(0,0)$ to $(2n,0)$ using the steps U and D by independently coloring their right-hand turns by blue or red. Replacing each consecutive blue UD by a $(2,0)$ step describes a bijection with Example 1.

Note 4 We will indicate a bijection from Example 4 to a reflected Example 3, reflected about the horizontal axis. The following proof is from the proof of [21, equation (5)]. We will also tilt our lattice paths by 45 degrees for the following.

Consider the steps $N := (0,1)$ and $E := (1,0)$. Let $A(n)$ denote the set of all paths from $(0,-1)$ to (n,n) which remain weakly above the horizontal axis except on the first step. A *left turn* is the intermediate point of a consecutive EN pair. Let $A_\ell(n)$ ($A_d(n)$, resp.) denote the set of replicated paths formed from $A(n)$ so each left turn (double ascent, resp.) is independently colored blue or red.

We have a bijection

$$F : A_d(n) \longrightarrow A_\ell(n)$$

defined as follows: Let $P \in A_d(n)$ be determined by the set (perhaps empty) of the coordinates of its left turns, namely $\{(x_1, y_1), \ldots, (x_k, y_k)\}$. Then $(x'_1, y'_1), \ldots, (x'_h, y'_h)$, $\ldots, (x'_{n-k}, y'_{n-k})$ are the left turns of the path $F(P) \in A_\ell(n)$ (This was mistyped in [21].) where

$$\begin{aligned} \{x'_1, \ldots, x'_{n-k}\} &= \{1, \ldots, n\} - \{x_1, \ldots, x_k\} \\ \{y'_1, \ldots, y'_{n-k}\} &= \{0, \ldots, n-1\} - \{y_1, \ldots, y_k\} \end{aligned}$$

with $x'_1 < x'_h < x'_{n-k}$ and $y'_1 < y'_h < y'_{n-k}$ and the left turn at (x'_h, y'_h) has the color blue (red, resp.) if, and only if, y'_h is the ordinate of the intermediate vertex of a blue (red, resp.) double ascent on P.

See also Note 14.

Note 5 A. Each path in Example 5 is sequence of consecutive oddly-evenly positioned step pairs. The morphism sending UU to U, UD to $(1,0)_2$, DU to $(1,0)_1$, and DD to D (where its subscripts indicate the weights) determines a weight preserving bijection from Example 5 to Example 2.

B. We give a bijection from Example 5 to Example 1, which constitutes a combinatorial solution for the *Monthly* problem [22]. Our bijective proof is in the *45-degree tilted* environment. In the following we will encode each path from each of the two examples as a triple of subsets of integers of the form (X, Y, H) where $X := \{x_1, \ldots, x_h, \ldots, x_i\} \subset \{1, \ldots, n\}$, $Y := \{y_1, \ldots, y_h, \ldots, y_i\} \subset \{1, \ldots, n\}$, and $H := \{h_1, \ldots, h_j\} \subset \{1, \ldots, i\}$ where i and j depend on the path. Since there will be a unique encoding triple for each path from each model we will have a bijection.

Let $\mathcal{A}(n)$ denote the set of lattice paths from $(0,0)$ to (n,n) that permit four step types: the horizontal step $(1,0)$, the uncolored step $(0,1)$ where this vertical step may assume only even positions in a path, and the steps $(0,1)_{\text{red}}$ or $(0,1)_{\text{green}}$ where these vertical steps may assume only odd positions in a path. Any path in $\mathcal{A}(n)$ having i of its horizontal steps in the even positions, $2x_1, \ldots, 2x_h, \ldots, 2x_i$, having necessarily i of its vertical steps in the odd positions, $2y_1 - 1, \ldots, 2y_h - 1, \ldots, 2y_i - 1$, and having exactly j red steps in positions, $2y_{h_1} - 1, \ldots, 2y_{h_j} - 1$, can be encoded as (X, Y, H).

Let $\mathcal{D}(n)$ denote the set of lattice paths from $(0,0)$ to (n,n) that permit the three step types: $(1,0)$, $(0,1)$, and the diagonal, $(1,1)$. By replacing each diagonal step with a blue $(0,1)(1,0)$ step pair (i.e., *a blue right-hand turn*), we can match each path in $\mathcal{D}(n)$ having j diagonal steps and $i - j$ uncolored right-hand turns with a marked path from $(0,0)$ to (n,n) that uses the two steps, $(1,0)$ and $(0,1)$, and has marked right-hand turns. Each resulting marked path is determined by the coordinates of the intermediate vertices of its right-hand turns, say, $(x_1 - 1, y_1)$, $\ldots$, $(x_h - 1, y_h)$, $\ldots$ $(x_i - 1, y_i)$, where those turns corresponding to $y_{h_1}, \ldots, y_{h_j}$ are colored blue. Hence, each path can be encoded as (X, Y, H).

See also Note 14.

Note 6 This example appears as exercise [16, 6.16] where a generating function proof is indicated. A combinatorial proof, as requested in [16], appears in [21] and uses some of the bijections of these notes.

Note 7 That the Delannoy numbers count this example follows from the initial discussion of Section 3. Presently we have no ideas for bijective considerations.

Note 8 A generating function argument, and consequently, the recurrence (2) for Example 8 appear in [20]. *The cut and paste bijection* of [10] gives an immediate bijection between this example and Example 1.

Note 9 *The cut and paste bijection* [10] gives an immediate bijection between this example and Example 7.

Note 10 *The cut and paste bijection* [10] gives an immediate bijection between this example and Example 2. See Note 11.

Note 11 In [18] a *zebra* is defined as a parallelogram polyomino having all (not just the noninitial) columns colored either black or white. In [18] generation function methods show that the sum of the average of the squares of the diagonal thicknesses of all zebras of a fixed perimeter is twice a Delannoy number. By extending the known bijection given in [5] (See also [18, Sect. 5].), we have a bijection between the configurations of Example 11 and those of Example 10.

Note 12 Sachs and Zernitz [11] discovered this example and its solution, giving them in terms of counting perfect matchings. Stanley [16, Exercise 6.49] records Dana Randell's restatement of the example and its solution in terms of Aztec diamonds.

Note 13 For $m = 1, 2, 3, \ldots$, let COMB_m denote the *comb graph* with m teeth. This graph has vertex set $\{1, 2, \ldots, 2m\}$ and edge set

$$\{\{1,2\},\{3,4\},\ldots,\{2m-1,2m\}\} \cup \{\{2,4\},\{4,6\},\ldots,\{2m-2,2m\}\}\,.$$

In addition to the example for d_n, Emeric Deutsch [6] discovered that the collection of sets of k pairwise nonadjacent edges of COMB_m has cardinality $d_{k,m-k}$. To see this one can establish a bijection from this collection to the collection of paths from $(0,0)$ to $(k, m-k)$ using the steps $(0,1), (1,0), (1,1)$. In particular, this bijection maps a set with j edges of the type $\{2i, 2i+2\}$ to a path with j steps of type $(1,1)$.

Note 14 For Dyck paths (i.e., paths running from $(0,0)$ to $(2n,0)$, using the steps U and D, and never running below the x-axis) there are many statistics which are distributed by the Narayana numbers [17]: namely, for $1 \le k \le n$,

$$\frac{1}{n}\binom{n}{k-1}\binom{n}{k}.$$

The three classic statistics are (i) the *number of peaks* (This is immediately equivalent both to number of valleys plus one and to the number of double ascents plus one.), (ii) the *number of ascents which are oddly positioned along the path*, and (iii) the *number of nonfinal longs* plus one. (See Examples 3, 4, and 5. The *plus one* term is unavoidable – it is in agreement with the need for both small and large Schröder numbers. (See [19].)

For unrestricted paths, if one assign a weight of 2 to each object (or substructure) counted by those statistics, computes the weight of each path, and then sums over the paths of a given length, one arrives at the Delannoy number as in Examples 3, 4, 5, and 14. That the assignment of the weight 2 to each objects counted by certain statistics yields a Delannoy number is in agreement with equation (4).

Kreweras and Moszkowski [7] introduced the *number of nonfinal longs* statistic for Dyck paths. Benchekroun and Moszkowski [2] then gave a bijective proof that this statistic indeed has the Narayana distribution: The number of Dyck paths of length $2n$, having k nonfinal longs is

$$|\mathcal{D}(n,k)| = \frac{1}{n}\binom{n}{k}\binom{n}{k+1}. \tag{5}$$

We use their proof to obtain a bijection between Example 14 and a modified Example 3, modified as to be in terms of left-hand turns (i.e., valleys, not peaks). To obtain the domain for this bijection we tilt the paths of Example 14 to run from $(0,-1)$ to (n,n) weakly above the x-axis except on the first step and to use the steps $(0,1)$ and $(1,0)$. The codomain will be the set of paths from $(0,0)$ to (n,n) with the unit steps $(0,1)$ and $(1,0)$. If (x_1,y_1), ..., (x_h,y_h), ..., (x_j,y_j) denote the locations of the next to the final lattice points on the long steps of a path in the domain, then (x_1+1,y_1), ..., (x_h+1,y_h) , ..., (x_j+1,y_{j-h}) will be the locations of the left-hand turns of the image path.

Note 15 Louis Shapiro [13] discovered this example. A bijection with the tilted version of Example 1 can be established recursively. Let $\mathcal{W}(x,y)$ denote the set of lattice walks of the Example 15 that have $x+y$ steps and final height y. Let $\mathcal{U}(x,y)$ denote the set of lattice path running from $(0,0)$ to (x,y) that use the steps $E := (1,0)$, $N := (0,1)$, and $D := (1,1)$. We define $f := \mathcal{W}(x,y) \rightarrow \mathcal{U}(x,y)$ so that $f(PE) = f(P)E$, $f(PWW) = f(PW)E$, $f(PNW) = f(P)D$, and $f(PN) = f(P)N$. With the obvious boundary conditions for $x = 0$ or $y = 0$, f can be shown to be bijective.

Note 16 This and the next example were found by Sylviane Schwer [12] and her interest in the Delannoy numbers resulted in [1]. More generally, she considered unlabeled balls of m colors with p_i balls having color i, for $i = 1 \ldots m$. For $\ell = max(p_1, p_2, \ldots, p_m)$ and $u = p_1 + p_2 + \cdots + p_m$, she made available $u - \ell + 1$ collections of urns where each collection has r urns, labeled by $1, 2, \ldots, r$, for $\ell \leq r \leq u$. With $D(p_1, p_2, \ldots, p_m)$ denoting the ways to distribute the balls so that in each urn there is a ball and no two balls have the same color, she showed that $D(p_1, p_2, \ldots, p_m)$ is isomorphic to the lattice paths in m-space that run from $(0, 0, \ldots, 0)$ to $(p_1, p_2, \ldots, p_m)$ using the nonzero steps of the form $(\epsilon_1, \epsilon_2, \ldots, \epsilon_m)$ where $\epsilon_i \in \{0, 1\}$. (See [14] for a discussion of multidimensional Delannoy numbers.)

Note 17 Continuing from note 16, Schwer formulated the enumeration of possible words which take as their alphabet nonempty subsets of some set $X = \{x_1, x_2, \ldots, x_m\}$. If $||f||_x$ denotes the number of occurrences of x in the subsets forming a word f, then the Parikh vector of f is denoted by $(||f||_{x_1}, ||f||_{x_2}, \ldots, ||f||_{x_m})$. The set of words with a Parikh vector equal to $(p_1, p_2, \ldots, p_m)$ has the cardinality of $D(p_1, p_2, \ldots, p_m)$.

Note 18 This example was found by M. Vassilev and K. Atanassov[23]. See *Math Rev.:* 96b:05004. More generally, their paper proves that $d_{p,q}$ counts $\{y \in \mathbb{Z}^p : ||y||_1 \leq q\}$.

Note 19 Let $\mathcal{P}(x_0)$ denote the set of unweighted paths using the steps, $(1,1)$ and $(1,-1)$, beginning at $(0,0)$, ending on the line $x = x_0$, and remaining weakly above the x-axis. Then

$$|\mathcal{P}(2k)| = \binom{2k}{k}. \tag{6}$$

To see (6), we first observe that the manner in which the paths of $P(2k-1)$ can be appended to form paths of $\mathcal{P}(2k)$ implies $|\mathcal{P}(2k)| = 2|\mathcal{P}(2k-1)|$. Likewise, $|\mathcal{P}(2k-1)| = 2|\mathcal{P}(2k-2)| - c_{k-2}$, where $c_{k-2} = \binom{2k-2}{k-1}/k$ is the Catalan number counting the paths in $\mathcal{P}(2k-2)$ which terminate at $(k-2,0)$. Since the central binomial coefficient satisfies $\binom{2k}{k} = 4\binom{2k-2}{k-1} - 2c_{k-2}$, (6) follows inductively.

To verify this example we count the ways to insert $n-k$ $(2,0)$-steps into any path of $\mathcal{P}(2k)$. Hence,

$$\sum_k \binom{2k}{k}\binom{n+k}{n-k} = \sum_k \frac{(2n)!}{k!k!(n-k)!} = \sum_k \binom{n}{k}\binom{n+k}{k} = d_n.$$

Note 20 Example 20 follows by labeling the peaks of Example 19 red and replacing the $(2,0)$-steps by a blue $(1,1)(1,-1)$ pair. It would be interesting to find a bijection involving an even earlier example.

Note 21 Let $\mathcal{D}(n,k)$ denote the set of lattice paths running from $(0,0)$ to $(n,0)$, using the steps U and D, never passing beneath the x-axis, and having k non-final longs. By Note 14, $|\mathcal{D}(n,k)|$ has the the Narayana distribution. Let $\mathcal{L}(n,k)$ denote the set of lattice paths running from $(0,0)$, having n steps of types U and D, never passing beneath the x-axis, and having k longs.

Since $\cup_{n>0}\mathcal{D}(n,k)$ can be decomposed with respect to the point of first return to the x-axis, we have, for $d := d(x,t) = \sum_{n\geq 0}\sum_{k\geq 0}|\mathcal{D}(n,k)|t^k x^n$,

$$d = 1 + x^2 d + x^2 t(d - 1 + (t-1)x^2 d)(d-1) + x^2(d + (t-1)x^2 d). \tag{7}$$

Here the next-to-the-last term corresponds to an intermediate first return to the x-axis; hence the first t is required to count the nonfinal long assumed by the D steps at that return. The $(t-1)x^2$ factors assure that initial double ascents followed by D steps are counted as being long.

Since $\cup_{n>0}\mathcal{L}(n,k)$ can be decomposed with respect to whether or not paths return to the x-axis for a last time, we have, for $\ell := \sum_{n\geq 0}\sum_{k\geq 0}|\mathcal{L}(n,k)|t^k x^n$,

$$\ell = 1 + x^2\ell + x^2 t(d - 1 + (t-1)x^2 d)\ell + x(\ell + (t-1)x + (t-1)x^2\ell). \tag{8}$$

The factors t, $(t-1)x$, and $(t-1)x^2$ are required somewhat as indicated in the above paragraph. Equations (7) and (8) easily yield, with the middle formula discounting paths of odd length,

$$\sum_n\sum_k |\mathcal{L}(2n,k)|2^k x^n = \frac{\ell(z,2) + \ell(-z,2)}{2} = \frac{1}{\sqrt{1-6z^2+z^4}}.$$

Note 22 The reader can establish a simple bijection between the paths giving the counts in this array and the paths of Example 19.

Note 23 Emeric Deutsch [6] contributed this example, which in turn motivated Examples 24 through 27. Essentially these examples consist of attaching a root of odd degree to a list of structures counted by the large Schröder numbers. One can establish a generating functional proof for this example similar to that of Note 24.

Note 24 Let $\mathcal{D}(n,k)$ denote the set of lattice paths running from $(0,0)$ to $(n,0)$, using the steps U and D, never passing beneath the x-axis, and having k peaks. If $d := d(x,t) = \sum_{n\geq 0}\sum_{k\geq 0}|\mathcal{D}(n,k)|t^k x^n$, one can decompose the paths with respect to the first return to the x-axis to show

$$d = 1 + tx^2 d + x^2(d-1)d.$$

For $t = 2$,

$$d(x,2) = \frac{1 - x^2 - \sqrt{1-6x^2+x^4}}{2x^2},$$

which is the generating function for the large Schröder numbers.

Let $\mathcal{P}(2n+2i, 2i)$ be as in the statement of Example 24. Since the paths of $\mathcal{P}(2n+2i,2i)$ are the concatenations of $2i-1$ elevated paths, each of which has generating function $x^2 d = x^2 d(x,2)$, we have

$$\sum_{m\geq 0}|\mathcal{P}(2m,2i)|x^2 = (x^2 d)^{2i-1}.$$

Hence,

$$\sum_{n\geq 0}\sum_{i\geq 1}|\mathcal{P}(2n+2i,2i)|x^{2n} = \sum_{i\geq 1}x^{-2i}\sum_{n\geq 0}|\mathcal{P}(2n+2i,2i)|x^{2n+2i},$$

which is equal

$$\sum_{i\geq 1}x^{-2i}(x^2 d)^{2i-1} = \sum_{j\geq 0}x^{2j}d^{2j+1} = \frac{d}{1-x^2d^2} = \frac{1}{\sqrt{1-6x^2+x^4}}.$$

Note 25 Refer to Notes 23 and 24.

Note 26 Refer to Notes 23 and 24.

Note 27 Refer to Notes 23 and 24.

Note 28 The reader can establish a simple bijection between this example and Example 1 or 16.

Note 29 The reader can establish a simple bijection between this example and Example 6.

Abstract

The purpose of this paper is to study the Parker vectors (in fact, sequences) of several known classes of oligomorphic groups. The Parker sequence of a group G is the sequence that counts the number of G-orbits on cycles appearing in elements of G. This work was inspired by Cameron's paper on the sequences realized by counting orbits on k-sets and k-tuples.

1 Introduction

In a recent paper [6], P. J. Cameron describes several "classical" sequences (in the sense of appearing in the *Encyclopedia of Integer Sequences* [12]) obtainable as U- or L-sequences of oligomorphic groups, that is as sequences of numbers counting the orbits of such groups on k-subsets and on ordered k-tuples, respectively.

Oligomorphic permutation groups [5] constitute a class of infinite groups to which it is meaningful to extend the concept of Parker vector, originally defined for finite groups (see

[8]). So it is natural to study which integer sequences are obtained as Parker sequence, that is, by counting orbits on k-cycles.

Recall that the *Parker sequence*, or *Parker vector*, of an oligomorphic permutation group G is the sequence $\mathbf{p}(G) = (p_1, p_2, p_3, \dots)$, where p_k is the number of orbits of G on the set of k-cycles appearing in elements of G, with G acting by conjugation. For instance, for the symmetric group S acting on a countable set, the Parker sequence is just $(1, 1, 1, \dots)$. A less trivial example is the group C preserving a circular order on a countable set; for the Parker sequence one has $p_k = \varphi(k)$

Let us fix the notation for some sequences needed in this paper: $\varphi(k)$ is the Euler (totient) function (A000010 in Sloane's *Encyclopedia* [12]), $d(k)$ is the number of divisors of k (A000005), and $\sigma(k)$ is the sum of the divisors of k (A000203).

2 Operators on sequences

Cameron [6] describes how obtaining "new groups from old" (mainly by taking direct and wreath product, and by taking the stabilizer) corresponds to operators on and transforms of their U- and L-sequences (in the sense of Sloane [13]).

Analogously, it is possible to study how the Parker sequences of "new" groups are related to those of "old" ones. The general effect on Parker sequences of taking direct and wreath products of groups is studied in the authors' papers [7] and [8].

Let G and H be permutation groups acting on the sets X and Y, respectively. Recall that, if we consider the direct product $G \times H$ acting on the disjoint union of X and Y, the U-sequence for $G \times H$ is obtained as CONV of the U-sequences of the factors (we are multiplying the ordinary generating functions of the sequences); on the other hand, the L-sequence of the direct product is obtained as EXPCONV (here one considers the exponential generating functions).

For the Parker sequences the corresponding operation is simply the sum (element by element):

$$p_k(G \times H) = p_k(G) + p_k(H).$$

Forming the direct product of G with the countable symmetric group S gives, as U-sequence, PSUM of the L-sequence of G; as L-sequence, BINOMIAL of its L-sequence. For the Parker sequence, it simply yields

$$p_k(G \times S) = p_k(G) + 1.$$

One may also consider the product action of $G \times H$ on the cartesian product $X \times Y$. For this action one has:

$$p_k(G \times H) = \sum_{\substack{i,j \\ \mathrm{lcm}(i,j)=k}} p_i(G) p_j(H).$$

What happens for wreath products is more interesting. Recall [7, 8] that for the Parker sequences of the wreath product of G and H the following holds:

$$p_k(G \wr H) = \sum_{d|k} p_d(G) p_{k/d}(G).$$

This is the Dirichlet convolution, which in the terminology of Sloane [13] is the DIRICHLET transform of the two sequences.

We may now study, for a given oligomorphic group H, the operator mapping the Parker sequence of any group G to that of $G \wr H$. For U-sequences, this procedure gives rise to the operators EULER, INVERT, and CIK, respectively for $H = S$, $H = A$, and $H = C$. For Parker sequences we get, for $H = S$, the MOBIUSi operator

$$p_k(G \wr S) = \sum_{d|k} p_d(G);$$

and, for $H = A$, the identity operator

$$p_k(G \wr A) = p_k(G).$$

For $H = C$ we get

$$p_k(G \wr C) = \sum_{d|k} p_d(G)\varphi(k/d);$$

in particular note that for square-free k's (that is, the values of k such that $\mu(k) \neq 0$) one has $p_k(G \wr C) = \varphi(k) \sum_{d|k} p_d(G)/\varphi(d)$.

Notice that, while in general $G \wr H$ and $H \wr G$ may be different groups, they have the same Parker sequence; so these operators are also those mapping $\mathbf{p}(G)$ to $\mathbf{p}(H \wr G)$.

3 Parker sequences and circulant relational structures

Recall [8] that, if we are dealing with a group G defined as the automorphism group of the limit of a Fraïssé class $\mathcal{F}$ of relational structures, the Parker sequence of G has an alternative interpretation as the sequence enumerating the finite circulant structures in that class. More precisely, the kth component of the Parker sequence counts the relational structures in (the age of) $\mathcal{F}$ on the set $\{1, 2, \ldots, k\}$ admitting as an automorphism the permutation $(1\ 2\ \ldots\ k)$ (note that this is different than just requesting that the structure admits a circular symmetry). In what follows we shall use "circulant [structure]" to mean "circulant [structure] on the set $\{1, 2, \ldots, k\}$ admitting the automorphism $(1\ 2\ \ldots\ k)$". All of the Parker sequences listed in the "Fraïssé class" table were obtained by counting these circulant structures.

This mirrors what happens with the L-sequence (F_k) of the same group, which is defined as the number of orbits on k-tuples of distinct elements, and is equal to the number of labelled structures on k points. The same holds for the U-sequence f_k of the number of orbits on k-sets, giving the number of unlabelled structures. The theory behind this can be found in Cameron's book [5].

In order to give an idea of the techniques involved in deriving Parker sequences, let us first briefly recall [8] what happens for graphs.

To describe a circulant graph Γ on the vertex set $\{0, 1, 2, \ldots, k-1\}$, it is sufficient to give the neighbours of a fixed vertex (say 0); this subset, which has the property that it contains a vertex i if and only if it contains $k-i$, is called *symbol* of Γ. On the other hand any subset

S of $\{1, 2, \ldots, k-1\}$ such that $i \in S$ implies $k - i \in S$ is a possible symbol for a graph. So the kth entry of the Parker sequence of the automorphism group of the limit of the Fraïssé class of graphs (that is the well-known random, or Erdős-Rényi, or Rado, graph) is $2^{\lfloor k/2 \rfloor}$.

Several variations to this method yield the Parker sequences for other relational structures.

For instance, if we consider the symbol for a digraph (a structure with a relation $\rightarrow$ in which for each pair of distinct vertices a, b, any of $a \rightarrow b$, $b \rightarrow a$, both, or none may hold) we choose whether or not to join, by putting a directed edge, 0 with any other vertex. So we get $p_k = 4^{(k-1)/2} = 2^{k-1}$. Similarly, if we do not allow a double orientation on an edge, we get the class of oriented graphs, for which $p_k = 3^{\lfloor k/2 \rfloor}$.

Of course, this kind of argument holds also for the class of n-ary relations, for $n \geq 2$. The symbol for a circulant n-relation on k points can be any possible set of $(n-1)$-tuples (admitting repetitions) of the points. For instance, for a ternary relation, we may have $(0, 0)$ (meaning that $(0, 0, 0)$ holds), $(0, 1)$, $(1, 0)$, $(1, 1)$, ... So we have k^{n-1} such $(n-1)$-tuples, and $2^{k^{n-1}}$ possible symbols (sets of such tuples).

More examples in same vein appear in the tables.

The same techniques can be applied to the class of two-graphs; this case, however, requires some care.

Recall that a *two-graph* is defined as a pair (X, T), where X is a set of points, and T a set of 3-subsets of X with the property that any 4-subset of X contains an even number of members of T.

Two-graphs on k vertices are in bijection with switching classes of graphs on k vertices. Recall that switching a graph $\Gamma = (V, E)$ with respect to $S \subseteq V$ gives a graph (V, E') such that $\{v, w\} \in E'$ if and only if either v and w are both in S or both in $V \setminus S$ and $\{v, w\} \in E$, or one is in S and the other is in $V \setminus S$, and $\{v, w\} \notin E$ (see [11], also for the description of the correspondence between two-graphs and switching classes).

Note that a two-graph (X, T) is circulant if and only if at least one graph in the corresponding switching class is. In fact, assume that α is a permutation of X inducing an automorphism of (X, T); then α induces an automorphism of at least one graph in the corresponding switching class (as proved by Mallows and Sloane [10]; see also Cameron [2]).

The following result relates circulant two-graphs to circulant graphs.

Theorem 3.1 *Let Γ be a circulant k-vertex graph. If k is odd, then Γ is the only circulant graph in its switching class; if k is even, there are exactly two circulant graphs in its switching class.*

In order to prove this, let us first show in some detail what happens switching circulant and regular graphs.

Proposition 3.2 *For k odd, in each switching class of graphs on k vertices there is at most one regular graph.*

Proof. Let Γ be a regular graph of valency r on k vertices. Let us switch it with respect to the set $S \subseteq V(\Gamma)$, $0 < |S| = m < k$. Then, for each $t \notin S$, call n_t the number of

neighbours of t included in S (before switching). Then the valency of t in the switched graph is $r - n_t + (m - n_t)$. Analogously, if $s \in S$ and n_s is the number of neighbours of s not in S, the valency of s in the switched graph is $r - n_s + (k - m - n_s)$.

Therefore, if the switched graph is regular, given two vertices s and t as above, their new valencies must be equal:

$$r - n_t + (m - n_t) = r - n_s + (k - m - n_s),$$

or,

$$k = 2(m - n_t + n_s).$$

That is, the number of vertices must be even for a non-trivial switching equivalence to hold between Γ and another regular graph. ♢

We have now the first part of the theorem (because any circulant graph must be, *a fortiori*, regular). For the second part, the following proposition describes explicitely when switching a circulant graph yields another circulant graph.

Proposition 3.3 *If Γ is a circulant graph on the vertices $\{1, 2, \ldots, k\}$, k even, the only non-trivial switching yielding a circulant graph is with respect to the set of vertices $S = \{1, 3, 5, \ldots, k-1\}$ (or its complement).*

Proof. For Γ to be circulant, it must be possible to decompose it in cycles $(i, i + l, i + 2l, \ldots, i - l)$ (all additions modulo k). In each such cycle the vertices either have all the same parity, or an odd and an even vertex alternate. So, switching with respect to S either preserves the whole cycle, or causes all its edges to vanish. In either case, the graph remains circulant.

On the other hand, if switching is performed with respect to any other non-trivial set S', this set or its complement must include two consecutive vertices i, $i+1$ (mod k) and of course there exists j such that $j \in S'$, $j + 1 \notin S'$. In a circulant graph either $1 \sim 2 \sim \cdots \sim k \sim 1$ or $1 \not\sim 2 \not\sim \cdots \not\sim k \not\sim 1$; assume, up to complementing, the former. Then in the switched graph $i \sim i + 1$ while $j \not\sim j + 1$; so the new graph is not circulant. ♢

A variation of the previous argument shows that the same holds for oriented two-graphs.

4 Groups and their sequences

In this section we consider the tables included in Cameron's paper [6] and add, as far as possible, the data concerning Parker sequences.

For the five closed highly homogeneous groups of Cameron's theorem (i.e., the groups admitting only one orbit on k-sets for all k; see [1]) the Parker sequences are readily obtained. Recall that S is the infinite symmetric group, A (or ∂C) is the subgroup of S of the permutations preserving the ordering on the rational numbers, B (or ∂C^*) of those preserving or reversing it, C of those preserving a cyclic order on a countable set (say, the complex roots of unity), and D (or C^*) of those preserving or reversing such a cyclic order.

The Parker sequence for S is clearly the all-1 sequence; while in the finite case this property characterises (with a single exception) the symmetric groups, in the infinite case this sequence is shared by other, not highly transitive groups. An instance of this fact is the group of the Fraïssé class of trees with the action on edges.

The Parker sequence for A is unremarkable, but for its being the neutral element for the Dirichlet convolution. So, for each group G, $\mathbf{p}(A \wr G) = \mathbf{p}(G \wr A) = \mathbf{p}(G)$.

The sequences for C and D can be obtained by noting that these groups induce on k-sets the groups C_k and D_k (dihedral of degree k), respectively; see also [8].

Highly Homogeneous Groups

Group	**Parker sequence**	**EIS entry**	**Notes**

$C \wr C$	$\sum_{d\|k} \varphi(d)\varphi(k/d) = 1, 2, 4, 5, 8, 8, 12, 12, 16, 16, \ldots$	A029935	See remark 3

Remark 1 The sequence is periodic of period $\mathrm{lcm}(1,\ldots,n)$.

Remark 2 The sequence associated with $S^{\wr n}$ (i.e., the iterated wreath product of S with itself with n factors) can be expressed as follows. Let $\delta_0(k) := 1$ for each k, and for $i > 0$ let

$$\delta_i(k) := \sum_{d|k} \delta_{i-1}(d),$$

that is, δ_i is the Dirichlet convolution $\delta_{i-1} * \delta_0$. Thus, $\delta_i(k) = p_k(S^{\wr i+1})$.

All the functions δ_i are multiplicative, because δ_0 is, and the Dirichlet convolution preserves multiplicativity. Thus, it suffices to compute the value of δ_i on prime powers.

We claim that

$$\delta_i(p^j) = \binom{i+j}{i}.$$

To obtain a different description of the δ_is, note that $\delta_1(k)$ gives the number of divisors of k, including 1 and k; so it is equal to $d(k)$. Next, $\delta_2(k)$ is the sum over the divisors of k of the number of their divisors; in other words, it gives the number of pairs (h,d) with $h|d$ and $d|k$ (observe that h and d may well coincide). In general, we see that $\delta_i(k)$ gives the number of i-ples $(d_1,d_2,\ldots,d_i)$ with $d_1|d_2$, …, $d_{i-1}|d_i$, $d_i|k$. We call such a sequence a *generalised gozinta chain*, recalling that a gozinta ("goes into") chain for k is a sequence of divisors of k each of which strictly divides the next one.

When $k = p^j$, a sequence of divisors of k each of which divides the next one corresponds to a nondecreasing sequence of exponents of p, that is to a nondecreasing sequence of numbers in $[j] = \{0,1,\ldots,j\}$, which in turn can be seen as a multiset of elements of $[j]$.

So, it is enough to enumerate the multisubsets of $\{0,1,\ldots,j\}$ of size i. It is well known (see for instance [14]) that their number is given by $\binom{i+j}{i}$, as claimed.

Remark 3 If k is square-free, p_k is equal to $\sum_{d|k} \varphi(k) = d(k)\varphi(k)$.

* * *

The following groups arise as automorphism groups of Fraïssé classes (see section 3).

The calculation of Parker sequences for "treelike objects" and related structures is carried out in detail in the forthcoming paper [9].

The letters R and L mean "shifted right" and "shifted left" respectively.

† Not in [6].

Remark 4 Each (symbol for a) circulant graph represents also its complement, so (for $k > 1$) each term is one half of the corresponding term for graphs. For instance, $p_2 = 1$ because the graphs K_2 and N_2 are now identified.

Remark 5 This is the number of symmetric sum-free subsets of $\mathbf{Z}/(k)^*$ (see [3]): if the symbol contains a and b, it cannot contain $a+b$, and (as for generic graphs) if it contains a, it must contain $k-a$.

Remark 6 We cannot exchange "black" and "white" vertices, so a circulant structure is an all-black or all-white null graph.

Remark 7 Reason as in section 3, but take in addition to "basic" circulant graphs (those with symbol of the form $\{i, k-i\}$) also that with k vertices, each with a loop attached, and no other edges. In other words, in the symbol (set of "neighbours" of 0) for a circulant graph with loops, also 0 may appear.

Remark 8 The "basic" graphs do not work as they are; the request for the relation to be transitive forces any k-gon to "become" a complete directed graph (that is, K_k where all edges are bidirected): by transitivity, connect vertices at distance 2, then at distance 3 and so on. The superposition of d copies of $K_{k/d}$ and l copies of $K_{k/l}$ becomes by transitivity the superposition of $\mathrm{GCD}(d,l)$ copies of $K_{\mathrm{lcm}(k/d,k/l)}$. So the lattice of divisors of k describes all the possible circulant transitive digraphs, that is topologies.

In other words, a topology is the transitive closure of a union of cyclic graphs; its incidence matrix can be seen as the kth power of the incidence matrix of the starting graph with, as its entries, boolean variables 0 and 1 (so that $1+1=1$).

Remark 9 By acyclicity, for each n the only circulant poset is the one with n incomparable elements.

Remark 10 The only possible distinguished sets are the empty and the full ones.

One Last Example

Group	**Parker sequence**	**EIS entry**	**Notes**
S^2 (product action)	$d(k^2)$	A048691	See rem. 11

Remark 11 The result follows from Section 2, keeping in mind that $d(k^2)$ is equal to the number of pairs (i,j) such that $\mathrm{lcm}(i,j) = k$.

Abstract

Succession rules having a rational generating function are usually called *rational succession rules*. In this note we discuss some problems concerning rational succession rules, and determine a simple method to pass from a rational generating function to a rational succession rule, both defining the same number sequence.

1 Introduction

A *succession rule* is a formal system defined by an *axiom* (a), $a \in \mathbb{N}^+$, and a set of *productions*

$$\{(k_t) \rightsquigarrow (e_1(k_t))(e_2(k_t)) \cdots (e_{k_t}(k_t)) : t \in \mathbb{N}\},$$

where $e_i : \mathbb{N}^+ \longrightarrow \mathbb{N}^+$, which explains how to derive the *successors* $(e_1(k)), (e_2(k)), \ldots, (e_{k_t}(k))$ of any given label (k), $k \in \mathbb{N}^+$. In general, for a succession rule Ω, we use the more compact notation:

$$\Omega : \begin{cases} (a) \\ (k) \rightsquigarrow (e_1(k))\ (e_2(k))\ \cdots\ (e_k(k)). \end{cases} \tag{1}$$

The *labels* (a), (k), $(e_i(k))$ of Ω are assumed to contain only positive integers. The rule Ω can be represented by means of a *generating tree*, that is, a rooted tree whose vertices are labelled with the labels of Ω: (a) is the label of the root, and each node labelled (k) has k children labelled by $e_1(k), \ldots, e_k(k)$ respectively, according to the production of (k) defined in (1). A succession rule Ω defines a sequence of positive integers $(f_n)_{n\geq 0}$, where f_n is the number of the nodes at level n in the generating tree defined by Ω. By convention the root is at level 0, so $f_0 = 1$. The function $f_\Omega(x) = \sum_{n\geq 0} f_n x^n$ is the *generating function* determined by Ω.

Succession rules are closely related to a method for the enumeration and generation of combinatorial structures, called the *ECO method*. For further details and examples about succession rules and the ECO method we refer to [BDLPP]; in [FPPR] the authors study succession rules from an algebraic point of view.

Two rules are *equivalent* if they have the same generating function. A succession rule is *finite* if it has a finite number of labels and productions; for example, the rule

$$\begin{cases} (2) \\ (2) \rightsquigarrow (2)(3) \\ (3) \rightsquigarrow (2)(3)(3), \end{cases} \tag{2}$$

defining odd-index Fibonacci numbers $1, 2, 5, 13, 34, 89, 233, \ldots$ (sequence A001519 in [SL]) is finite and it is equivalent to

$$\begin{cases} (2) \\ (k) \rightsquigarrow (2)^{k-1}(k+2), \end{cases} \tag{3}$$

which is not finite.

Figure 1 depicts the first levels of the generating trees associated with the rules in (2) and (3).

According to our definition, two labels containing the same integer k are allowed to have a different production. If this happens we distinguish those labels using some indices (or *colors*, see Example 1). A succession rule is called *rational*, *algebraic* or *trascendental* according to the generating function type. Rational succession rules are the subject of this note (see also [GFGT], [FPPR]).

Below we list some classes of generating functions:

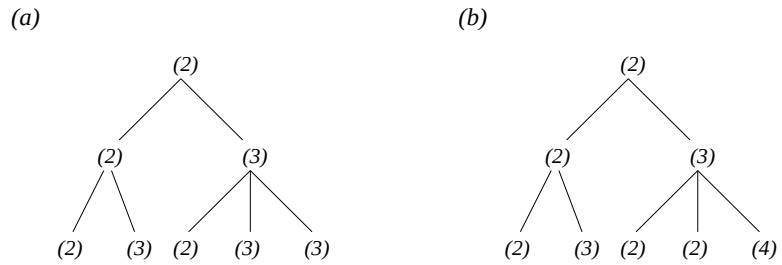

Figure 1: The first levels of two equivalent generating trees.

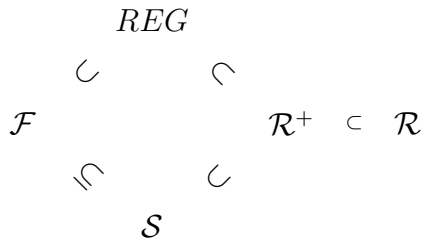
- $\mathcal{R}$ is the set of rational generating functions of integer sequences (Z-rational functions, using the notation in [SS]);
- $\mathcal{R}^+$ is the set of rational generating functions of positive integer sequences;
- REG is the set of generating functions of regular languages;
- $\mathcal{S}$ is the set of rational generating functions of succession rules;
- $\mathcal{F}$ is the set of generating functions of finite succession rules.

Summarizing the results in [SS], [FPPR] we obtain the following scheme:



The classes $\mathcal{R}$, REG, and $\mathcal{F}$ are decidable, while $\mathcal{R}^+$ is not decidable. In [FPPR] is conjectured that $\mathcal{F} = \mathcal{S}$, i.e., every rational rule is equivalent to a finite one.

This note proposes a simple tool to pass from a rational generating function (i.e., a linear recurrence relation) defining a non-decreasing sequence of positive integers to a succession rule defining the same sequence. The results extend those in [GFGT].

Furthermore our technique provides interesting combinatorial interpretations (in terms of generating trees) for sequences that are defined by a linear recurrence relation, using an approach different from that in [BDFR] and [BR].

As an application of our method, we give a simple solution to a problem proposed by Jim Propp on the mailing list "domino" (1999), where he asked for the combinatorial interpretation of the sequence $1, 1, 1, 2, 3, 7, 11, 26, \ldots$ (sequence A005246 in [SL]) defined by the linear recurrence relation:

$$\begin{cases} f_0 = 1, \quad f_1 = 1, \quad f_2 = 1, \quad f_3 = 2 \\ f_n = 4f_{n-2} - f_{n-4}. \end{cases}$$

2 Two term linear recurrences.

We start by considering two-term linear recurrences:

$$f_n = h_1 f_{n-1} + h_2 f_{n-2}, \qquad h_1, h_2 \in \mathbb{Z}$$

with initial conditions $f_0 = 1$, $f_1 = s_0 \in \mathbb{N}^+$. The positivity of the sequence is ensured by the additional conditions $h_1 \in \mathbb{N}^+$, and $h_1 + h_2 > 0$.

Proposition 1 *The succession rule*

$$\Omega = \begin{cases} (s_0) \\ (k) \rightsquigarrow (1)^{k-1} (\phi(k)), \end{cases}$$

with $\phi(k) = (h_1 - 1)k + h_2 + 1$, *defines the sequence* $(f_n)_{n \geq 0}$.

Proof. We have $f_0 = 1$ and $f_1 = s_0$. Let $k_1, k_2, \ldots, k_{f_{n-2}}$ be the labels at level $n-2$ of the generating tree of Ω. Then, for $n \geq 2$,

$$f_n = k_1 + k_2 + \cdots + k_{f_{n-2}} - f_{n-2} + (h_1 - 1)(k_1 + k_2 + \cdots + k_{f_{n-2}}) + f_{n-2}(h_2 + 1).$$

Consequently we have

$$f_n = f_{n-1} - f_{n-2} + (h_1 - 1)f_{n-1} + f_{n-2}(h_2 + 1) = h_1 f_{n-1} + h_2 f_{n-2} \quad n \geq 2. \blacksquare$$

A succession rule defining the sequence $(f_n)_{n \geq 0}$ can however have a more general form, such as:

$$\Omega_2 = \begin{cases} (s_0) \\ (k) \rightsquigarrow (c)^{k-1} (\phi(k)) \end{cases}$$

where $c, s_0 \in \mathbb{N}^+$, $\phi(k) = (h_1 - c)k + h_2 + c$, and the positivity of the labels is ensured by the following conditions:

(i) if $c \leq s_0$ then $1 \leq c \leq h_1$ and $((h_1 - c)c + h_2 + c) > 0$;

(ii) if $c > s_0$ then $s_0 \leq c \leq h_1$ and $((h_1 - c)s_0 + h_2 + c) > 0$.

3 Linear recurrences with more than two terms.

In this section we consider the general case of linear recurrences defining non-decreasing sequences of positive integers, and we give the explicit form of succession rules defining such sequences.

For the sake of simplicity, let us start by studying the case of three term recurrences of the form

$$f_n = h_1 f_{n-1} + h_2 f_{n-2} + h_3 f_{n-3},$$

with $f_{-1} = 0$, $f_0 = 1$, $f_1 = s_0 \in \mathbb{N}^+$, where $h_1 \in \mathbb{N}^+$ and $h_2, h_3 \in \mathbb{Z}$.

On the other hand, let us consider the rule

$$\Omega_3 = \begin{cases} (s_0) \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^0(k)) & k = s_0, c \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^1(k)) \end{cases}$$

where $c \in \mathbb{N}^+$, and

$$\phi^0(k) = (h_1 - c)k + h_2 + c,$$

$$\phi^1(k) = (h_1 - c)k + h_2 + h_3 + c.$$

The following conditions easily ensure that the labels of Ω_3 are positive and, as a consequence, the sequence defined by Ω_3 is positive and non-decreasing.

(i) If $c \leq s_0$ then $1 \leq c \leq h_1$, $(\phi^0(c)) > 0$ and $\phi^1\,(\phi^0(c)) > 0$.

(ii) If $c > s_0$ then $s_0 \leq c \leq h_1$, $(\phi^0(s_0)) > 0$ and $\phi^1\,(\phi^0(s_0)) > 0$.

Proposition 2 *The succession rule Ω_3 defines the sequence $(f_n)_{n\geq 0}$.*

Proof. We can easily verify that $f_0 = 1$, $f_1 = s_0$ and $f_2 = h_1 s_0 + h_2$. For $n \geq 3$ the number of occurrences of the label c at level $n-3$ is equal to $f_{n-2} - f_{n-3}$, so we obtain

$$f_n = cf_{n-1} - cf_{n-3} + (h_1 - c)f_{n-1} + (h_2 + h_3 + c)f_{n-3} - c\,(f_{n-2} - f_{n-3}) + (h_2 + c)(f_{n-2} - f_{n-3}),$$

which simplifies to $f_n = h_1 f_{n-1} + h_2 f_{n-2} + h_3 f_{n-3}$ for $n \geq 3$. ∎

Example 1 The sequence $(f_n)_{n\geq 0}$ satisfying the recurrence relation

$$f_n = 3f_{n-1} - 2f_{n-2} + f_{n-3},$$

with $f_1 = 0$, $f_0 = 1$, $f_1 = 2$, is defined by the succession rule

$$\begin{cases} (2) \\ (1) \rightsquigarrow (1) \\ (2) \rightsquigarrow (1)(3) \\ (k) \rightsquigarrow (1)^{k-1}(2k) & k \geq 3. \end{cases}$$

In the sequel we will extend the statement of Proposition 2 to the general case of linear recurrences.

Let us consider the rule

$$\Omega_j = \begin{cases} (s_0) \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^0(k)) & k = s_0,\ c \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^1(k)) & k = \phi^0(s_0),\ \phi^0(c) \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^2(k)) & k = \phi^1\,(\phi^0(s_0)),\ \phi^1\,(\phi^0(c)) \\ \vdots \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^{j-3}(k)) & k = \{\ \phi^{j-4}(\phi^{j-5}(\cdots\phi^1(\phi^0(x)))) :\ x = s_0, c\ \} \\ (k) \rightsquigarrow (c)^{k-1}\,(\phi^{j-2}(k))\,, \end{cases}$$

where $c, s_0, h_1 \in \mathbb{N}^+$, $h_2, h_3, \ldots, h_j \in \mathbb{Z}$, and

$$\phi^m(k) = (h_1 - c)k + \sum_{i=1}^{m+1} h_{i+1} + c, \qquad m = 0, \ldots, j-2.$$

The following conditions determine the positivity of the labels of Ω_j:

(i) if $c \le s_0$ then $1 \le c \le h_1$, $\phi^{i-2}\,(\phi^{i-1}(\cdots\phi^0(c)))$, $i = 2, \ldots, j$;

(ii) if $c > s_0$ then $s_0 \le c \le h_1$, $\phi^{i-2}\,(\phi^{i-1}(\cdots\phi^0(s_0)))$, $i = 2, \ldots, j$.

Theorem 1 *The succession rule Ω_j defines the non-decreasing positive sequence satisfying the recurrence relation:*

$$f_n = h_1 f_{n-1} + h_2 f_{n-2} + \cdots + h_j f_{n-j},$$

with initial conditions $f_i = 0$, $i = -j+2, \ldots, -1$, $f_0 = 1$, and $f_1 = s_0$.

Proof. Analogous to that of Proposition 2. ■

Example 2 (i) NSW numbers (sequence A002315 in [SL]) are defined by the recurrence relation:

$$f_n = 6f_{n-1} - f_{n-2}, \qquad f_0 = 1,\ f_1 = 7.$$

These numbers count the total area under elevated Schröder paths [PP, BSS]. According to Theorem 2, the succession rule defining these numbers is

$$\begin{cases} (7) \\ (k) \rightsquigarrow (1)^{k-1}(5k) \end{cases}$$

(ii) Self-avoiding walks of length n, contained in the strip $\{0,1\} \times [-\infty, \infty]$, are counted by the sequence $\{f_n\}$ that satisfies a linear recurrence relation [Z]:

$$\begin{array}{ll} f_0 = 1,\ f_1 = 3,\ f_2 = 6,\ f_3 = 12,\ f_4 = 20,\ f_5 = 36,\ f_6 = 58,\ f_7 = 100, & \\ f_n = f_{n-1} + 3f_{n-2} + 2f_{n-3} - 3f_{n-4} + f_{n-5} + f_{n-6} & n > 7. \end{array} \tag{4}$$

For simplicity we change the initial conditions into the following:

$$\begin{aligned} &f_{-i} = 0, \quad i = 1, \ldots, 5 \\ &f_0 = 1. \end{aligned}$$

Then the succession rule obtained applying Theorem 1 is

$$\begin{cases} (1) \\ (1) \rightsquigarrow (4) \\ (3) \rightsquigarrow (1)^2(\overline{4}) \\ (4) \rightsquigarrow (1)^3(6) \\ (\overline{4}) \rightsquigarrow (1)^3(5) \\ (5) \rightsquigarrow (1)^4(5) \\ (6) \rightsquigarrow (1)^5(3). \end{cases}$$

For clarity's sake, we want to point out that the label (4) is produced by $\phi^0(c)$, and it is subject to the rule involving ϕ^1, while the label $(\overline{4})$ is subject to the rule involving ϕ^4.

Finally, we remark that a rule defining the original number sequence can be simply obtained by adding some other productions, in order to satisfy the initial conditions.

Example 3 Now we are able to give a succession rule for the number sequence $1, 1, 1, 2, 3, 7, 11, 26, \ldots$, defined in the first part of the paper. Omitting for simplicity the initial constant terms we have

$$\begin{cases} (2) \\ (2) \rightsquigarrow (1)(2) \\ (1) \rightsquigarrow (4) \\ (4) \rightsquigarrow (1)^3(\overline{1}) \\ (3) \rightsquigarrow (1)^2(\overline{1}) \\ (\overline{1}) \rightsquigarrow (3). \end{cases}$$

Succession rules with negative labels. Theorem 2 clearly does not involve the whole set $\mathcal{R}$ of rational generating functions. Moreover, as we already remarked, the problem of establishing if a rational generating function defines a non-negative sequence of integers is undecidable, and then if we want to treat the whole set of rational generating functions we have to allow labels of the rules to contain negative values. Under this hypothesis a succession rule defines a sequence of integer numbers $(f_n)_{n\geq 0}$, not necessarily positive, where the term f_n is given by the number of positive labels minus the number of negative labels at level n of the generating tree.

Recently we investigated the relationship between rational generating functions and succession rules with negative labels (briefly *generalized succession rules*) by applying the same tools that we used in the first part of the paper. Furthermore we determined an algorithm to pass from a rational generating function to a generalized succession rule. However this algorithm has a rather complex description, and moreover it does not give an answer to the conjecture $\mathcal{F} = \mathcal{S}$. Therefore, for the sake of simplicity, we only present the following examples.

Example 4 Let us consider the number sequence $1, 2, -10, 22, -26, -10, 134, \ldots$, defined by the recurrence relation

$$\begin{array}{l} f_0 = 1,\ f_1 = 2, \\ f_n = -3f_{n-1} - 4f_{n-2} \quad n > 1. \end{array}$$

The succession rule defining this sequence is

$$\begin{cases} (4) \\ (k) \rightsquigarrow (1)^{k-1}(-2k-1) \\ (-k) \rightsquigarrow (-1)^{k-1}(2k+1). \end{cases}$$

Example 5 Odd-index Fibonacci numbers with alternating sign, $1, -2, 5, -13, 34, -89, \ldots$, are defined by the recurrence relation

$$\begin{array}{l} f_0 = 1,\ f_1 = -2, \\ f_n = -3f_{n-1} - f_{n-2} \quad n > 1. \end{array}$$

A succession rule defining this sequence is

$$\begin{cases} (2) \\ (k) \rightsquigarrow (-1)^{k-1}(-2k) \\ (-k) \rightsquigarrow (1)^{k-1}(2k). \end{cases}$$

We point out that the rule (5) is very similar to (3), which defines the odd-indexed Fibonacci numbers.

A Common Generating Function for Catalan Numbers and Other Integer Sequences

G. E. Cossali
Università di Bergamo
24044 Dalmine
Italy
cossali@unibg.it

Abstract

Catalan numbers and other integer sequences (such as the triangular numbers) are shown to be particular cases of the same sequence array $g(n,m) = \frac{(2n+m)!}{m!n!(n+1)!}$. Some features of the sequence array are pointed out and a unique generating function is proposed.

1 Introduction

Catalan numbers can be found in many different combinatorial problems, as shown by Stanley [1], and exhaustive information about this sequence can be found in [2]. In this note I show that the Catalan numbers (A000108) and other known sequences (triangular numbers A000217, A034827, A001700, A002457, A002802, A002803, A007004, A024489) can be derived by the same generating function and are related to the same polynomial set.

2 The polynomials $j_m(y)$

Consider the following recurrence relation defining the polynomials $j_m(y)$:

$$\begin{gathered} j_0(y) = 1; \\ j_{m+1}(y) = y j_m(y) + \sum_{s=0}^{m} j_s(y)\, j_{m-s}(y). \end{gathered} \tag{1}$$

It may immediately be noticed that for $y = 0$ this formula coincides with the recursive definition of the Catalan numbers:

$$C_{s+1} = \sum_{m=0}^{s} C_m C_{s-m} \tag{2}$$

where

$$C_n = \frac{2n!}{n!(n+1)!} = \frac{1}{n+1}\binom{2n}{n}. \tag{3}$$

This means that C_n is the zero-order coefficient of the nth-order polynomial $j_n(y)$, i.e.,

$$j_m(y) = \sum_{q=0}^{m} e(m,q)\ y^q \tag{4}$$

and $e(m,0) = C_m$. The first few values of $e(m,q)$ are shown in Table 1.

$m \diagdown q$	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
0	1							
1	1	1						
2	2	3	1					
3	5	10	6	1				
4	14	35	30	10	1			
5	42	126	140	70	15	1		
6	132	462	630	420	140	21	1	
7	429	1716	2772	2310	1050	252	28	1

Table 1: Some of the coefficients $e(m,q)$

Equation (4) can be introduced into (1) to obtain

$$\sum_{q=0}^{m+1} e(m+1,q)\ y^q = \sum_{q=0}^{m} e(m,q)\ y^{q+1} + \sum_{s=0}^{m}\sum_{p=0}^{m-s} e(m-s,p)\ \sum_{r=0}^{s} e(s,r)\ y^{p+r}$$

and transformed as follows:

$$\begin{aligned}
&\textstyle\sum_{q=0}^{m+1} e(m+1,q)\ y^q = \sum_{q=1}^{m+1} e(m,q-1)\ y^q + \sum_{s=0}^{m}\sum_{p=0}^{m-s} e(m-s,p)\ \sum_{r=0}^{s} e(s,r)\ y^{p+r} = \\
&= \textstyle\sum_{q=1}^{m+1} e(m,q-1)\ y^q + \sum_{p=0}^{m}\ \sum_{r=0}^{m-p}\ y^{p+r}\ \left[\sum_{s=r}^{m-p} e(m-s,p)\ e(s,r)\right] = \\
&= \textstyle\sum_{q=1}^{m+1} e(m,q-1)\ y^q + \sum_{p=0}^{m}\ \sum_{q=p}^{m}\ y^q\ \left[\sum_{s=q-p}^{m-p} e(m-s,p)\ e(s,q-p)\right] = \\
&= \textstyle\sum_{q=1}^{m+1} e(m,q-1)\ y^q + \sum_{q=0}^{m}\ \sum_{p=0}^{q}\ \left[\sum_{s=q-p}^{m-p} e(m-s,p)\ e(s,q-p)\right] y^q = \\
&= \textstyle\sum_{q=1}^{m+1} e(m,q-1)\ y^q + \sum_{q=0}^{m}\ \sum_{p=0}^{q}\ \left[\sum_{l=q}^{m} e(m-l+p,p)\ e(l-p,q-p)\right] y^q.
\end{aligned}$$

The following set of equations can then be obtained for any natural number m:

(1) for $q = 0$:

$$e(m+1,0) = \sum_{s=0}^{m} e(m-s,0)\ e(s,0),$$

whose solution is

$$e(m,0) = C_m = \frac{1}{m+1}\binom{2m}{m}. \tag{5}$$

(2) for $0 < q \leq m$:

$$e(m+1,q) = e(m,q-1) + \sum_{p=0}^{q} \sum_{l=q}^{m} e(m-l+p,p)\ e(l-p,q-p). \tag{6}$$

(3) for $q = m+1$:

$$e(m+1,m+1) = e(m,m) = \cdots = 1. \tag{7}$$

It is useful to introduce the modified matrix $g(n,k)$ defined as follows:

$$\begin{array}{l} g(n,k) = e(n+k,k) \\ e(n,k) = g(n-k,k) \end{array} \tag{8}$$

Table 2 reports the first few values:

$m \diagdown q$	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
0	1	1	1	1	1	1	1	1
1	1	3	6	10	15	21	28	36
2	2	10	30	70	140	252	420	660
3	5	35	140	420	1050	2310	4620	8580
4	14	126	630	2310	6930	18018	42042	90090
5	42	462	2772	12012	42042	126126	336336	816816
6	132	1716	12012	60060	240240	816816	2450448	6651216
7	429	6435	51480	291720	1312740	4988412	16628040	49884120

Table 2: Some values of the coefficients $g(m,q)$

Equations (5), (6), (7) then become:

(1) for $q = 0$:

$$g(n,0) = C_n. \tag{9}$$

(2) for $0 < q \leq n+1$:

$$g(n+1,q) = g(n+1,q-1) + \sum_{p=0}^{q} \sum_{l=0}^{n} g(n-l,p)\ q(l,q-p), \tag{10}$$

where $m-q$ was replaced by $n = m-q$. Moreover, from (7) we get $g(0,n) = 1$.

The solution of (10) can be written as follows:

$$g(n,q) = \frac{(2n+q)!}{q!n!(n+1)!} = C_n \binom{2n+q}{q}. \tag{11}$$

In fact, (9) is satisfied, and substituting (11) into (10), we get

$$\begin{aligned} C_{n+1}\binom{2(n+1)+q}{q} \;&=\; C_{n+1}\binom{2(n+1)+q-1}{q-1} + \\ &+ \sum_{l=0}^{n} C_{n-l}C_l \left[\sum_{p=0}^{q} \binom{2(n-l)+p}{p} \binom{2l+q-p}{q-p} \right] \end{aligned} \tag{12}$$

It is possible to show that (see appendix)

$$\sum_{p=0}^{q} \binom{2(n-l)+p}{p}\binom{2l+q-p}{q-p} = \binom{2n+q+1}{q},$$

and

$$\binom{2(n+1)+q}{q} - \binom{2(n+1)+q-1}{q-1} = \binom{2(n+1)+q-1}{q-1}\left[\frac{2(n+1)+q}{q} - 1\right]$$

$$= \left\{\frac{[2(n+1)+q-1]!}{[q-1]!\,[2(n+1)]!}\right\}\left[\frac{2(n+1)}{q}\right] = \left\{\frac{(2n+q+1)!}{q!\,(2n+1)!}\right\} = \binom{2n+q+1}{q}.$$

By using the recursive definition (2) of Catalan numbers, (12) becomes an indentity.

3 Some features of the array $g(n,q)$

The sequence

$$g(n,q) = \frac{2n+q!}{q!n!(n+1)!} = C_n\binom{2n+q}{q}$$

can be seen as a generalization of the Catalan sequence, as it reduces to the Catalan sequence for $q = 0$. There are also some other interesting features. In Table 3 I report the known names of the integer sequences, referenced in *The On-line Encyclopedia of Integer Sequences* [2], that can be extracted from the matrix $g(n,q)$.

Table 3: $g(m,q)$ numbers and names of known sequences

The first five columns correspond to the known sequences: A000108 (Catalan), A001700, A002457, A002802, A002803. The first two rows correspond to the sequences A000217 ($g(1,q)$, triangular numbers) and A034827. For the other rows and columns no reference was found by the author. Also the sequence on the main diagonal $g(k,k)$ (1,3,30,420,6930,126126,...) is known as A007004 and the sequence on the diagonal $g(k,k+1)$ (1,6,70,1050,18018, ...) is known as A024489.

4 Generating function

Consider the algebraic equation in J:

$$-xJ^2 + (1 - yx)J - 1 = 0, \tag{13}$$

and its solutions

$$J(x, y) = \frac{(1 - yx) \pm \sqrt{(1 - yx)^2 - 4x}}{2x}. \tag{14}$$

Let now suppose that $J(x, y)$ admits a Taylor expansion in x (which excludes the solution $J(x, y) = \frac{(1-yx)+\sqrt{(1-yx)^2-4x}}{2x}$ unlimited in $x = 0$)

$$J(x, y) = \sum_{m=0}^{\infty} j_m (y) x^m. \tag{15}$$

Substituting (15) into equation (13) we get

$$\begin{array}{c} 0 = -x \sum_{m=0}^{\infty} j_m (y) x^m \sum_{m=0}^{\infty} j_n (y) x^n + \sum_{m=0}^{\infty} j_m (y) x^m - yx \sum_{m=0}^{\infty} j_m (y) x^m - 1 = \\ = -x \sum_{s=0}^{\infty} j_s (y) \sum_{m=s}^{\infty} j_{s-m} (y) x^s + \sum_{m=0}^{\infty} j_m (y) x^m - y \sum_{m=0}^{\infty} j_m (y) x^{m+1} - 1 = \\ = - \sum_{s=0}^{\infty} \sum_{m=0}^{s} j_s (y) j_{s-m} (y) x^{s+1} + \sum_{s=0}^{\infty} j_s (y) x^s - y \sum_{s=0}^{\infty} j_s (y) x^{s+1} - 1 = \\ = j_0(y) - 1 + \sum_{s=0}^{\infty} \left[- \sum_{m=0}^{s} j_s (y) j_{s-m} (y) + j_{s+1} (y) - y j_{s-1} (y) \right] x^{s+1}. \end{array}$$

Then

$$\begin{array}{c} j_0(y) = 1 \\ j_{s+1} (y) = y \ j_s (y) + \sum_{m=0}^{s} j_s (y) j_{s-m} (y) , \end{array} \tag{16}$$

which is the recursive definition given by (1). This means that

$$j_m (y) = \lim_{x \to 0} \frac{1}{m!} \frac{d^m J(x, y)}{dx^m},$$

and for $y = 0$ the function $J(x, 0)$ is the generating function of the Catalan sequence

$$\begin{array}{c} j_m(0) = C_m \\ J(x, 0) = \frac{1-\sqrt{1-4x}}{2x} = C_a(x). \end{array}$$

Now, using Equations (4) and (15), we get

$$\begin{array}{c} J(x, y) = \sum_{m=0}^{\infty} \sum_{q=0}^{m} e(m, q) \ y^q x^m = \sum_{q=0}^{\infty} \sum_{m=q}^{\infty} e(m, q) \ y^q x^m = \\ = \sum_{q=0}^{\infty} y^q \sum_{m=0}^{\infty} e(m + q, q) \ x^{m+q} = \sum_{q=0}^{\infty} (yx)^q \sum_{m=0}^{\infty} g(m, q) \ x^m. \end{array} \tag{17}$$

Then, the function

$$L(x, z) = \frac{(1 - z) - \sqrt{(1 - z)^2 - 4x}}{2x} = J(x, z/x)$$

can be expanded to get (see equation (17))

$$L(x,z)=\sum_{q=0}^{\infty}\sum_{m=0}^{\infty}g(m,q)\ x^m z^q, \tag{18}$$

and this can be seen to be the generating function of $g(m,q)$:

$$g(m,q)=\lim_{x,z\to 0}\frac{1}{m!q!}\frac{\partial^{m+q}L(x,z)}{\partial x^m\partial z^q}.$$

It is interesting to observe that

$$\begin{aligned}L(x,z) &= \sum_{q=0}^{\infty}\sum_{m=0}^{\infty}g(m,q)\ x^m z^q=\sum_{m=0}^{\infty}C_m\sum_{q=0}^{\infty}\binom{2m+q}{q}z^q x^m=\\ &= \sum_{m=0}^{\infty}C_m T_m(z)x^m\end{aligned}$$

with

$$T_m(z)=\sum_{q=0}^{\infty}\binom{2m+q}{q}z^q.$$

It can be proven that

$$T_m(z)=\frac{1}{(1-z)^{2m+1}}$$

as

$$\frac{1}{q!}\frac{d^q T_m(z)}{dz^q}=\frac{(2m+1)\cdots(2m+q)}{q!\ (1-z)^{2m+1+q}}$$

and

$$\lim_{z\to 0}\frac{1}{q!}\frac{d^q T_m(z)}{dz^q}=\frac{(2m+q)!}{q!\ 2m!}=\binom{2m+q}{q}.$$

The generating function $L(x,z)$ can then be written also in the form

$$L(x,z)=\frac{1}{(1-z)}\sum_{n=0}^{\infty}C_n\left[\frac{x}{(1-z)^2}\right]^n=\frac{1}{(1-z)}C_a\left[\frac{x}{(1-z)^2}\right]$$

that better shows the strong link existing between the sequence array $g(n,q)$ and the Catalan numbers.

5 Appendix

The following binomial identity:

$$\sum_{p=0}^{q}\binom{m+p}{m}\binom{n+q-p}{n}=\binom{m+n+q+1}{q} \tag{19}$$

holds for any non-negative integers m, n, q.

Proof. We define

$$M(m,n,q) = \sum_{p=0}^{q} \binom{m+p}{m}\binom{n+q-p}{n}.$$

Then the proposition (19) is equivalent to

$$M(m,n,q) = \binom{m+n+q+1}{q}$$

The proof is based on the use of the binomial identity

$$\sum_{k=r}^{n} \binom{k}{r} = \binom{n+1}{r+1} \tag{20}$$

that can also be written as

$$\sum_{k=0}^{m} \binom{r+k}{r} = \binom{m+r+1}{r+1}.$$

The identity (19) holds for $n = 0$ and any m, q. In fact,

$$M(m,0,q) = \sum_{p=0}^{q} \binom{m+p}{m}\binom{q-p}{0} = \sum_{p=0}^{q} \binom{m+p}{m} = \binom{m+q+1}{m+1} = \binom{m+q+1}{q},$$

where the binomial identity (20) was used.

For any $n \neq 0$, using (20) again, and with q, m natural numbers,

$$\begin{aligned} M(m,n,q) &= \textstyle\sum_{p=0}^{q} \binom{m+p}{m}\binom{n+q-p}{n} = \sum_{p=0}^{q} \binom{m+p}{m}\binom{(n-1)+q-p+1}{(n-1)+1} = \\ &= \textstyle\sum_{p=0}^{q} \binom{m+p}{m} \sum_{k=0}^{q-p} \binom{n-1+k}{n-1} = \sum_{k=0}^{q} \sum_{p=0}^{q-k} \binom{m+p}{m}\binom{n-1+k}{n-1} = \\ &= \textstyle\sum_{k=0}^{q} \binom{q-k+m+1}{m+1}\binom{n-1+k}{n-1} = M(m+1,n-1,q). \end{aligned}$$

By repeatedly applying the rule $M(m,n,q) = M(m+1,n-1,q)$, it is easy to obtain

$$M(m,n,q) = M(m+n,0,q) = \binom{m+n+q+1}{q}.$$

Yemen
E-mail: benoumhani@yahoo.com

Abstract. Let $L(n,k)=\frac{n}{n-k}\binom{n-k}{k}$. We prove that all the zeros of the polynomial $L_n(x)=\sum_{k\geq 0} L(n,k)x^k$ are real. The sequence $L(n,k)$ is thus strictly log-concave, and hence unimodal with at most two consecutive maxima. We determine those integers where the maximum is reached. In the last section we prove that $L(n,k)$ satisfies a central limit theorem as well as a local limit theorem.

1. Introduction

A positive real sequence $(a_k)_{k=0}^n$ is said to be *unimodal* if there exist integers $k_0, k_1, 0 \leq k_0 \leq k_1 \leq n$ such that

$$a_0 \leq a_1 \leq \cdots \leq a_{k_0} = a_{k_0+1} = \cdots = a_{k_1} \geq a_{k_1+1} \geq \cdots \geq a_n.$$

The integers l, $k_0 \leq l \leq k_1$ are called the *modes* of the sequence. If $k_0 < k_1$ then $(a_k)_{k=0}^n$ is said to have a *plateau* of $k_1 - k_0 + 1$ elements; if $k_0 = k_1$ then it is said to have a *peak*. A real sequence is said to be *logarithmically concave* (log-concave for short) if

$$a_k^2 \geq a_{k-1}a_{k+1}, \quad 1 \leq k \leq n-1 \qquad (1)$$

If the inequalities in (1) are strict, then $(a_k)_{k=0}^n$ is said to be *strictly log-concave* (SLC for short). A sequence is said to be have *no internal zeros* if $i < j$, $a_i \neq 0$ and $a_j \neq 0$, then $a_k \neq 0$ for $i \leq k \leq j$. A log-concave sequence with no internal zeros is obviously unimodal, and if it is SLC, then it has at most two consecutive modes. The following result is sometimes useful in proving log-concavity. For a proof of this theorem, see Hardy and Littlewood [5].

Theorem 1. *(I. Newton) Let $(a_k)_{k=0}^n$ be a real sequence. Assume that the polynomial $P(x)=\sum_{k=0}^n a_k x^k$ has only real zeros. Then*

$$a_k^2 \geq \frac{n-k+1}{n-k}\cdot\frac{k+1}{k}a_{k+1}a_{k-1}, \quad 1 \leq k \leq n-1. \qquad (2)$$

If the sequence $(a_k)_{k=0}^n$ is positive and satisfies the hypothesis of the previous theorem, then it is SLC. The two possible values of the modes are given by the next theorem.

Theorem 2. *Let $(a_k)_{k=0}^n$ be a real sequence satisfying the hypothesis of the previous theorem. Then every mode of the sequence $(a_k)_{k=0}^n$ satisfies*

$$\left\lfloor \frac{\sum_{k=1}^{n} k a_k}{\sum_{k=0}^{n} a_k} \right\rfloor \leq k_0 \leq \left\lceil \frac{\sum_{k=0}^{n} k a_k}{\sum_{k=0}^{n} a_k} \right\rceil,$$

where $\lfloor x \rfloor$ and $\lceil x \rceil$ are respectively the floor and the ceiling of x.

For a proof of this theorem, see Benoumhani [2, 3].

Let $g(n,k) = \binom{n-k}{k}$. This sequence was been investigated by S. Tanny and M. Zuker [8]; they proved that it is SLC, and determined its modes. If r_n is the smallest mode of $g(n,k)$, then

$$r_n = \left\lceil \frac{5n - 3 - \sqrt{5n^2 + 10n + 9}}{10} \right\rceil . \qquad (3)$$

They proved that there are infinitely many integers where a double maximum occurs. The integers where this happen are given by: $n_j = F_{4j} - 1$, where F_k is the k^{th} Fibonacci number. The smallest mode corresponding to n_j is given by $r_j = \frac{1}{5}(L_{4j-1} - 4)$, where L_j is the j'th Lucas number.

In this paper we consider the sequence $L(n,k) = \frac{n}{n-k}\binom{n-k}{k}$, $0 \leq k \leq \lfloor \frac{n}{2} \rfloor$, $n \geq 1$. It is known that $L(n,k)$ counts the number of ways of choosing k points, no two consecutive, from a collection of n points arranged in a circle; see Stanley [7, p. 73, Lemma 2.3.4] and Sloane [6, A034807].

In Section 2, for the sake of completeness, we prove that all zeros of the polynomials $P_n(x) = \sum_{k \geq 0} g(n,k) x^k$ are real. The explicit formula for $P_n(x)$ allows us to derive some identities. Also it enables us to rediscover a result of S. Tanny and M. Zuker. In the third section, we consider the polynomials $L_n(x) = \sum_{k \geq 0} L(n,k) x^k$. We prove that all zeros of $L_n(x)$ are real and negative. In this case, too, the explicit formula for $L_n(x)$ gives some identities. The SLC of the sequence $L(n,k)$ is deduced from the fact that $L_n(x)$ has real zeros. We determine the modes, and the integers n where $L(n,k)$ has a double maximum. In the last section we prove that the sequence $L(n,k)$ is asymptotically normal, and satisfies a local limit theorem on R.

2. The polynomials $P_n(x)$

It is well known that the sequence $g(n,k) = \binom{n-k}{k}$, $0 \leq k \leq \lfloor \frac{n}{2} \rfloor$, is related to the Fibonacci numbers by the relation $\sum_{k \geq 0} \binom{n-k}{k} = F_{n+1}$. Recall that the sequence (F_n) is defined as follows:

$$F_n = F_{n-1} + F_{n-2},\ n \geq 2,$$

with $F_0 = 0$, $F_1 = 1$. Also we have the explicit formula

$$F_n = \frac{1}{\sqrt{5}} \left(\left(\frac{1+\sqrt{5}}{2} \right)^n - \left(\frac{1-\sqrt{5}}{2} \right)^n \right).$$

It is straightforward to see that $P_n(x)$ satisfies the recursion

$$P_n(x) = P_{n-1}(x) + xP_{n-2}(x), \qquad (4)$$

with initial conditions $P_0(x) = P_1(x) = 1$. Using the relation (4) we prove

Proposition 3. *For all $n \geq 0$, all zeros of the polynomials $P_n(x)$ are real. More precisely, we have* $P_n(x) = \frac{1}{\sqrt{4x+1}} \left(\left(\frac{1+\sqrt{4x+1}}{2} \right)^{n+1} - \left(\frac{1-\sqrt{4x+1}}{2} \right)^{n+1} \right). \quad (5)$

Proof. Write the relation (4) in matrix form, as follows: $\begin{pmatrix} P_n(x) \\ P_{n-1}(x) \end{pmatrix} = \begin{pmatrix} 1 & x \\ 1 & 0 \end{pmatrix} \begin{pmatrix} P_{n-1}(x) \\ P_{n-2}(x) \end{pmatrix}$. We deduce

$$\begin{pmatrix} P_n(x) \\ P_{n-1}(x) \end{pmatrix} = \begin{pmatrix} 1 & x \\ 1 & 0 \end{pmatrix}^{n-1} \begin{pmatrix} P_1(x) \\ P_0(x) \end{pmatrix} = \begin{pmatrix} 1 & x \\ 1 & 0 \end{pmatrix}^{n-1} \begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

The eigenvalues of the matrix $A = \begin{pmatrix} 1 & x \\ 1 & 0 \end{pmatrix}$ are

$$\lambda_1 = \frac{1+\sqrt{4x+1}}{2}\ ,\ \lambda_2 = \frac{1-\sqrt{4x+1}}{2},$$

and two eigenvectors of A are $V_1 = \begin{pmatrix} \lambda_1 \\ 1 \end{pmatrix}$ and $V_2 = \begin{pmatrix} \lambda_2 \\ 1 \end{pmatrix}$. Now the matrix A may be written

$$\begin{pmatrix} 1 & x \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} \lambda_1 & \lambda_2 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} \begin{pmatrix} \lambda_1 & \lambda_2 \\ 1 & 1 \end{pmatrix}^{-1}.$$

From this, we obtain

$$\begin{aligned} \begin{pmatrix} 1 & x \\ 1 & 0 \end{pmatrix}^{n-1} &= \frac{1}{\lambda_1 - \lambda_2} \begin{pmatrix} \lambda_1 & \lambda_2 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} \lambda_1^{n-1} & 0 \\ 0 & \lambda_2^{n-1} \end{pmatrix} \begin{pmatrix} 1 & -\lambda_2 \\ -1 & \lambda_1 \end{pmatrix} \\ &= \frac{1}{\lambda_1 - \lambda_2} \begin{pmatrix} \lambda_1^n - \lambda_2^n & -\lambda_1^n\lambda_2 + \lambda_1\lambda_2^n \\ \lambda_1^{n-1} - \lambda_2^{n-1} & -\lambda_1^{n-1}\lambda_2 + \lambda_1\lambda_2^{n-1} \end{pmatrix}. \end{aligned}$$

The vector $\begin{pmatrix} P_n(x) \\ P_{n-1}(x) \end{pmatrix}$ is now

$$\begin{pmatrix} P_n(x) \\ P_{n-1}(x) \end{pmatrix} = \frac{1}{\lambda_1 - \lambda_2} \begin{pmatrix} \lambda_1^n - \lambda_2^n & -\lambda_1^n\lambda_2 + \lambda_1\lambda_2^n \\ \lambda_1^{n-1} - \lambda_2^{n-1} & -\lambda_1^{n-1}\lambda_2 + \lambda_1\lambda_2^{n-1} \end{pmatrix} \begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

So,

$$P_n(x) = \frac{1}{\lambda_1 - \lambda_2} \left(\lambda_1^n - \lambda_2^n - \lambda_1^n\lambda_2 + \lambda_1\lambda_2^n \right).$$

Since $\lambda_1 + \lambda_2 = 1$ and $\lambda_1 - \lambda_2 = \sqrt{4x+1}$, we finally obtain

$$P_n(x) = \frac{1}{\sqrt{4x+1}} \left(\left(\frac{1+\sqrt{4x+1}}{2} \right)^{n+1} - \left(\frac{1-\sqrt{4x+1}}{2} \right)^{n+1} \right).$$

This is the desired result.

For the roots of $P_n(x)$, we have

$$P_n(x)=0 \Longleftrightarrow \left(\frac{1+\sqrt{4x+1}}{1-\sqrt{4x+1}}\right)^{n+1}=1 \Longleftrightarrow \left(\frac{1+\sqrt{4x+1}}{1-\sqrt{4x+1}}\right)=\varepsilon_k, 1\leq k\leq \left\lfloor \frac{n}{2}\right\rfloor$$

where the ε_k are the $(n+1)^{th}$ roots of unity. Thus,

$$P_n(x)=0 \Longleftrightarrow \sqrt{4x+1}=\frac{\varepsilon_k-1}{\varepsilon_k+1} \Longleftrightarrow 4x=-1+\left(\frac{\varepsilon_k-1}{\varepsilon_k+1}\right)^2.$$

Furthermore, we obtain $P_n(x)=0 \Longleftrightarrow x=-\frac{1}{4}\left(1+\tan^2\left(\frac{k\pi}{n+1}\right)\right), 1\leq k\leq \left\lfloor \frac{n}{2}\right\rfloor$. This proves that the roots of $P_n(x)$ are real and negative. □

Remark. In the sequel, we need Lucas numbers. Let us recall their definition:

$$L_n=L_{n-1}+L_{n-2}, \quad L_0=2,\ L_1=1.$$

It is not hard to see that

$$L_n=\left(\frac{1+\sqrt{5}}{2}\right)^n+\left(\frac{1-\sqrt{5}}{2}\right)^n \quad \text{and} \quad L_n=F_n+F_{n-2},$$

holds.

Corollary 4. *We have the following identities:*

1. $\sum\limits_{n\geq 0} P_n(x)z^n=\frac{1}{1-z-xz^2}$.

2. $\sum\limits_{k\geq 0}(-1)^k\binom{n-k}{k}=\begin{cases} 0,\ if\ n=6k+2,\ 6k+5; \\ 1,\ if\ n=6k,\ 6k+1; \\ -1,\ if\ n=6k+3,\ 6k+4. \end{cases}$

3. $\sum\limits_{k\geq 0} k\binom{n-k}{k}=\sum\limits_{k=0}^{n-2} F_kF_{n-k-2}=\frac{(n+1)L_n-2F_n}{5}=\frac{(n-1)F_n+(n+1)F_{n-2}}{5}$.

4. $(n+1)L_n-2F_n=(n-1)F_n+(n+1)F_{n-2}\equiv 0 \pmod 5$.

5. $\sum\limits_{k\geq 0}(-1)^k k\binom{n-k}{k}=\begin{cases} \frac{2}{3}n, & \text{if } n=6k; \\ \frac{n-1}{3}, & \text{if } n=6k+1; \\ -\frac{n+1}{3}, & \text{if } n=6k+2; \\ -\frac{2n}{3}, & \text{if } n=6k+3; \\ -\frac{(n-1)}{3}, & \text{if } n=6k+4; \\ \frac{n+1}{3}, & \text{if } n=6k+5. \end{cases}$

Proof. The first is known and easy to establish using (4). For (2), put $x=-1$ in (5). For the third, differentiate the generating function of $P_n(x)$ with respect to x, and compare the coefficients, and then put $x=1$. Relation 4 is immediate from 3. For the last one, put $x=-1$ in the derivative of $P_n(x)$. □

According to Theorem 2, every mode r_n of the sequence $\binom{n-k}{k}$ satisfies the relation

$$\left\lfloor \frac{\sum_{k=1}^{n} k\binom{n-k}{k}}{F_n} \right\rfloor \leq r_n \leq \left\lceil \frac{\sum_{k=0}^{n} k\binom{n-k}{k}}{F_n} \right\rceil.$$

S. Tanny and M. Zuker gave an exact formula for r_n, but this is somewhat opaque. So they used another method to give a more explicit one; but it is less precise. Namely, they proved that $r_n = \left\lfloor \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rfloor$ or $r_n = \left\lceil \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rceil$. We give another proof of this result.

Proposition 5. *(S. Tanny, M. Zuker [8])*

The modes of the sequences $\binom{n-k}{k}$ *are given by* $r_n = \left\lfloor \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rfloor$ *or* $r_n = \left\lceil \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rceil$.

Proof. Since all zeros of the polynomial $P_n(x)$ are real, it suffices to compute $\frac{\sum_{k=1}^{n} k\binom{n-k}{k}}{F_n} = \frac{\sum_{k=1}^{n} k\binom{n-k}{k}}{F_n}$. The last corollary gives

$$\mu_n = \frac{\sum_{k=1}^{n} k\binom{n-k}{k}}{F_n} = \frac{(n+1)L_n - 2F_n}{5F_n} = \frac{(n+1)L_n}{5F_n} - \frac{2}{5}.$$

Using the explicit formula for the Lucas and Fibonacci numbers; we obtain

$$\mu_n = \frac{(n+1)}{2}\left(1-\frac{\sqrt{5}}{5}\right)\frac{1+a^n}{1-a^{n+1}},\ a = -\frac{3-\sqrt{5}}{2}.$$

Now consider the sequence

$$\mu_n = \frac{(n+1)}{2}\left(1-\frac{\sqrt{5}}{5}\right)\frac{1+a^n}{1-a^{n+1}} - \frac{2}{5} = \frac{(n+1)}{2}\left(1-\frac{\sqrt{5}}{5}\right)A_n - \frac{2}{5},$$

where

$$A_n = \frac{1+a^n}{1-a^{n+1}}.$$

Also, observe that for every n we have

$$A_{2n+1} < 1 < A_{2n}.$$

So

$$\mu_{2n} = \frac{2n+1}{2}\left(1-\frac{\sqrt{5}}{5}\right)A_{2n} - \frac{2}{5} \geq \frac{2n+1}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5},$$

and

$$\mu_{2n+1} = \frac{2n+2}{2}\left(1-\frac{\sqrt{5}}{5}\right)A_{2n+1} - \frac{2}{5} \leq \frac{2n+2}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5}.$$

Thus

$$\frac{2n+1}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5} \leq \mu_{2n} \leq \mu_{2n+1} \leq \frac{2n+2}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5}.$$

We deduce that for every $n \geq 2$,

$$\frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5} \leq \mu_n \leq \frac{n+2}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5}.$$

Since the difference between the two bounds is $\left(1-\frac{\sqrt{5}}{5}\right) < 1$; there is a unique integer r_n in the interval $\left(\frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5}, \frac{n+2}{2}\left(1-\frac{\sqrt{5}}{5}\right) - \frac{2}{5}\right)$ and of course $r_n = \left\lfloor \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rfloor$ or $r_n = \left\lceil \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rceil$. □

3. The polynomials $L_n(x)$

In this section, we consider the sequence $L(n,k) = \frac{n}{n-k}\binom{n-k}{k}$. We prove that all zeros of the polynomials $L_n(x) = \sum_{k\geq 0} L(n,k)x^k$ are real.

Proposition 6. *For all $n \geq 2$, all zeros of the polynomials $L_n(x)$ are real. We have $L_n(x) = \left(\frac{1+\sqrt{4x+1}}{2}\right)^n + \left(\frac{1-\sqrt{4x+1}}{2}\right)^n$. (6).*

Proof. Since the polynomials satisfy the recursion

$$L_n(x) = L_{n-1}(x) + xL_{n-2}(x);$$

with $L_0 = 2$, $L_1 = 1$, the proof is exactly the same as for $P_n(x)$.

Corollary 7. *We have the following identities:*

1. $\sum_{n\geq 0} L_n(x)z^n = \frac{2-z}{1-z-xz^2}$.
2. $\sum_{k\geq 0} \frac{n}{n-k}\binom{n-k}{k} = L_n$.
3. $\sum_{k\geq 0}(-1)^k \frac{n}{n-k}\binom{n-k}{k} = \begin{cases} 1, \ if \ \ n = 6k+1 \ \ or \ \ 6k+5; \\ -1, \ if \ \ n = 6k+2 \ \ or \ \ 6k+4; \\ 2, \ \ if \ \ n = 6k\,; \\ -2, \ if \ \ n = 6k+3. \end{cases}$
4. $\sum_{k=0}^{n-1} L_k F_{n-k-1} = nF_n$.

Proof. Relation (1) is immediate, for the second one, it suffices to put $x = 1$ in (6). For the third one, put $x = -1$ again in (6). The last one is obtained by differentiating the generating function of $L_n(x)$ with respect to x and then equating the coefficients of z^n in both sides. □

Since all zeros of the polynomials $L_n(x)$ are real, it follows that the sequence $L(n,k)$ is SLC. We follow S. Tanny and M. Zuker to give the modes.

Theorem 8. *The smallest mode of the sequence $L(n,k)$ is given by*

$$k_n = \left\lceil \frac{5n-4-\sqrt{5n^2-4}}{10} \right\rceil.$$

Proof. The integer k_n satisfies

$$\begin{cases} L(n,k_n-1) < L(n,k_n) & (a) \\ L(n,k_n) \geq L(n,k_n+1) & (b) \end{cases}$$

Let

$$f(x) = 5x^2 - (5n+6)x + n^2 + 3n + 2,$$

and

$$g(x) = 5x^2 - (5n-4)x + n^2 + 2n + 1.$$

We have

$$\begin{aligned} (a) &\iff f(k_n) > 0; \\ (b) &\iff g(k_n) \leq 0. \end{aligned}$$

The roots of the first equation are $\frac{5n+6\pm\sqrt{5n^2-4}}{10}$, and those of the second one are $\frac{5n-4\pm\sqrt{5n^2-4}}{10}$. The desired integer satisfies

$$\frac{5n-4-\sqrt{5n^2-4}}{10} \leq k_n < \frac{5n+6-\sqrt{5n^2-4}}{10}.$$

Which is what we wanted. □

The previous formula for k_n is not as explicit as expected. We give a more explicit one.

Corollary 9. *The integer k_n satisfies the following*
$k_n = \left\lfloor \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rfloor$ *or* $k_n = \left\lceil \frac{n}{2}\left(1-\frac{\sqrt{5}}{5}\right)\right\rceil$.

Proof. The proof is the same as for r_n . □

In the next result, the integers n, such that the sequence $L(n,k)$ has a double maximum will be determined. Before determining these integers, we need the following lemmas:

Lemma 10. *For every $n \geq 0$, $5F_n^2 + 4(-1)^n = L_n^2$.*

Proof. This is known, and straightforward using the explicit formulas of F_n and L_n . □

Lemma 11. *For every $n \geq 0$, $5F_{4n+1} - L_{4n+1} - 4 \equiv 0 \pmod{10}$.*

Proof. Again, the explicit formulas of F_n and L_n give easily the wanted result. □

Theorem 12. *The sequence $L(n,k)$ has a double maximum if and only if $n = F_{4j+1}$, and in this case the smallest mode is given by $k_n = F_{2j}^2$.*

Proof. If l is the smallest mode of $L(n,k)$ then it satisfies

$$L(n,l) = L(n,\, l+1),$$

which is equivalent to

$$f(n,l) = 5l^2 - (5n-4)l + n^2 - 2n + 1 = 0\,. \qquad (7)$$

Equation (7) has two roots in l

$$l_{1,\,2} = \frac{5n-4\pm\sqrt{5n^2-4}}{10}.$$

The solution greater than $\frac{n}{2}$ is rejected, since the modes of $L(n,k)$ are less than $\frac{n}{2}$. The smallest one remains, i.e.,

$$l = \frac{5n-4-\sqrt{5n^2-4}}{10}\ . \qquad (8)$$

So, we are looking for all pairs of integers (n_j, k_j), $0 \leq k_j \leq \frac{n_j}{2}$, satisfying (7) (or (8)). We may transform (8) to an equation related to Pell's equation as in Tanny and Zuker [8], and then use some classical facts about units (invertible elements) in quadratic fields (see Cohn [4] for details). But we proceed differently: by Lemma 10, $5F_{2j+1}^2 - 4 = L_{2n+1}^2$, and by Lemma 11, $5F_{4j+1} - 4 - \sqrt{5F_{4j+1}^2 - 4} \equiv 5F_{4j+1} - 4 - L_{4j+1} \equiv 0 \pmod{10}$, that is, $k_j = \frac{55F_{4j+1}-4\pm\sqrt{5F_{4j+1}^2-4}}{10} = \frac{5F_{4j+1}-4-L_{4j+1}}{10} = F_{2j}^2 \leq \frac{F_{4j+1}}{2}$. So, some of the Fibonacci numbers are certainly among the n_j. Now let $(n_0,k_0) = (1,0)$, $(n_1,k_1) = (5,1)$, $(n_2,k_2) =$

$(34, 9)$, $(n_3, k_3) = (233, 64)$, ...,with $n_j = F_{4j+1}$, $k_j = F_{2j}^2$. The following recursions are easily derived:

$$\begin{cases} n_{j+1} = 7n_j - n_{j-1}; \\ k_{j+1} = 7k_j - k_{j-1} + 2\,. \end{cases} \tag{9}$$

Now, we prove that all solutions of (7) are in fact $(n_j = F_{4j+1},\, k_j = F_{2j}^2)_{j\geq 0}$. We will show that if (n_j, k_j) is a solution of (7), then

$$(n_{j+1}, k_{j+1}) = (7n_j - n_{j-1}, 7k_j - k_{j-1} + 2)$$

is another one. Indeed

$$\begin{aligned} f(n_{j+1}, k_{j+1}) &= 5k_{j+1}^2 - (5n_{j+1} - 4)k_{j+1} + n_{j+1}^2 - 2n_{j+1} + 1 \\ &= 5(7k_j - k_{j-1} + 2)^2 - (5(7n_j - n_{j-1}) - 4)(7k_j - k_{j-1} + 2) \\ &\quad +(7n_j - n_{j-1})^2 - 2(7n_j - n_{j-1}) + 1 \\ &= 0 \end{aligned}$$

since $f(n_i, k_i) = 5k_i^2 - (5n_i - 4)k_i + n_i^2 - 2n_i + 1 = 0$ for $0 \leq i \leq j$. Suppose that (n, k) is another one, $0 \leq k \leq \frac{n}{2}$; different from those (n_j, k_j). There is a unique (n_i, k_i) such that $n_i < n < n_{i+1}$. We verify easily that $f(7n - n_{i-1}, 7k - k_{i-1} + 2) = 0$. This means that $(n, k) = (n_i, k_i)$, and proves that all the solutions of (7) are given by the recursions (9).This ends the proof. □

Remarks. 1. There is a relation between the modes of the sequence $g(n, k)$ and those of $L(n, k)$. Let (m_j, r_j) be the sequence of integers such that $g(m_j, r_j) = g(m_j, r_j + 1)$. Since $m_j = F_{4j} - 1$,and $r_j = \frac{1}{5}(L_{4j-1} - 4)$, it is easy to establish (by direct calculations, or generating functions of r_j), that

$$\begin{cases} n_j = r_{j+1} - r_j; \\ k_j = m_j - 2r_j - 1. \end{cases}$$

2. Note that our relation for k_j was derived by S. Tanny and M. Zuker [9, p. 301]. There, the initial conditions for the Fibonacci numbers are: $F_0 = F_1 = 1$.

3. Using the recursions (9), we obtain the generating functions:

$$g(x) = \sum_{j=0}^{\infty} n_j x^j = \frac{1 - 2x}{1 - 7x + x^2} \quad \text{and} \quad h(x) = \sum_{j=1}^{\infty} k_j x^j = \frac{x + x^2}{(1 - x)(1 - 7x + x^2)}.$$

4. A central and a local theorem for $L(n, k)$

A positive real sequence $a(n, k)_{k=0}^{n}$, with $A_n = \sum_{k=0}^{n} a(n, k) \neq 0$, is said to satisfy a central limit theorem (or is *asymptotically normal*) with mean μ_n and variance σ_n^2 if

$$\lim_{n \longrightarrow +\infty} \sup_{x \in R} \left| \sum_{0 \leq k \leq \mu_n + x\sigma_n} \frac{a(n, k)}{A_n} - (2\pi)^{-1/2} \int_{-\infty}^{x} e^{-\frac{t^2}{2}} dt \right| = 0.$$

The sequence satisfies a local limit theorem on $B \subseteq R$; with mean μ_n and variance σ_n^2 if

$$\lim_{n \longrightarrow +\infty} \sup_{x \in B} \left| \frac{\sigma_n a(n, \mu_n + x\sigma_n)}{A_n} - (2\pi)^{-1/2} e^{-\frac{x^2}{2}} \right| = 0.$$

Recall the following result (see Bender [1]).

Theorem 13. *Let $(P_n)_{n\geq 1}$ be a sequence of real polynomials; with only real negative zeros. The sequence of the coefficients of the $(P_n)_{n\geq 1}$ satisfies a central limit theorem; with $\mu_n = \frac{P_n^{"}(1)}{P_n(1)}$ and $\sigma_n^2 = \left(\frac{P_n^{"}(1)}{P_n(1)} + \frac{P_n^{'}(1)}{P_n(1)} - \left(\frac{P_n^{'}(1)}{P_n(1)}\right)^2\right)$ provided that $\lim\limits_{n\longrightarrow+\infty} \sigma_n^2 = +\infty$. If, in addition, the sequence of the coefficients of each P_n is with no internal zeros; then the sequence of the coefficients satisfies a local limit theorem on R.*

The fact that the zeros of the sequence $L_n(x)$ are real implies the following result.

Theorem 14. *The sequence $(L(n,k))_{k\geq 0}$ satisfies a central limit and a local limit theorem on R with $\mu_n = \frac{L_n^{"}(1)}{L_n(1)} \sim \frac{n}{2}\left(1 - \frac{\sqrt{5}}{5}\right)$ and $\sigma_n^2 = \frac{L_n^{"}(1)}{L_n(1)} + \frac{L_n^{'}(1)}{L_n(1)} - \left(\frac{L_n^{'}(1)}{L_n(1)}\right) \sim 5^{-\frac{3}{4}} n$*

Proof. We have

$$\sigma_n^2 = \frac{L_n^{"}(1)}{L_n(1)} + \frac{L_n^{'}(1)}{L_n(1)} - \left(\frac{L_n^{'}(1)}{L_n(1)}\right)^2 = \frac{n^2 L_{n-2}L_n - 5n^2 F_{n-1}}{5L_n^2} + \frac{3nF_{n-1} - nL_{n-2}}{5L_n}.$$

Let $\alpha = \frac{1+\sqrt{5}}{2}$, $\beta = \frac{1-\sqrt{5}}{2}$. Using the explicit formulas of L_n and F_n, we obtain

$$\sigma_n^2 = \frac{(-1)^n n^2}{\alpha^{2n} + \beta^{2n} + 2(-1)^n} + \frac{\alpha^{n-2}\left(\frac{3\sqrt{5}\alpha}{5} - 1\right)n - \beta^{n-2}\left(\frac{3\sqrt{5}\beta}{5} + 1\right)n}{5\left(\alpha^n + \beta^n\right)} \sim 5^{-\frac{3}{4}} n.$$

So, $\lim\limits_{n\longrightarrow+\infty} \sigma_n = +\infty$. The local limit theorem is then easily seen to be satisfied; since $L(n,k) \neq 0$, for $0 \leq k \leq \left\lfloor \frac{n}{2} \right\rfloor$. □

As a consequence of the local limit theorem, we have

Corollary 15. *Let $L = \max\{L(n,k),\ 0 \leq k \leq \frac{n}{2}\}$. Then*

$$L \sim \frac{5^{\frac{3}{4}}\left(\frac{1+\sqrt{5}}{2}\right)^n}{\sqrt{2\pi n}}.$$

Acknowledgments: My sincere thanks to Andreas Dress and Jean-Louis Nicolas for their valuable corrections and comments.

Abstract

Aronson's sequence 1, 4, 11, 16, ... is defined by the English sentence "t is the first, fourth, eleventh, sixteenth, ... letter of this sentence." This paper introduces some numerical analogues, such as: $a(n)$ is taken to be the smallest positive integer greater than $a(n-1)$ which is consistent with the condition "n is a member of the sequence if and only if $a(n)$ is odd." This sequence can also be characterized by its "square", the sequence $a^{(2)}(n) = a(a(n))$, which equals $2n+3$ for $n \geq 1$. There are many generalizations of this sequence, some of which are new, while others throw new light on previously known sequences.

1. Introduction

Aronson's sequence is defined by the English sentence "t is the first, fourth, eleventh, sixteenth, ... letter of this sentence (not counting spaces or commas)," and is a classic example of a self-referential sequence ([3], [8], sequence M3406 in [13], A5224 in [12]). It is somewhat unsatisfactory because of the ambiguity in the English names for numbers over 100 — for example, some people say "one hundred and one", while others say "one hundred one." Another well-known example is Golomb's sequence, in which the n^{th} term $G(n)$ (for $n \geq 1$) is the number of times n appears in the sequence (A1462 in [12]):

$$1, 2, 2, 3, 3, 4, 4, 4, 5, 5, 5, 6, 6, 6, 6, 7, 7, 7, 7, 8, \ldots$$

There is a simple formula for $G(n)$: it is the nearest integer to (and approaches)

$$\phi^{2-\phi} n^{\phi-1} \ ,$$

where $\phi = (1+\sqrt{5})/2$ ([5], [6, Section E25]).

Additional examples can be found in Hofstadter's books [7], [8] and in [6] and [12]. However, the sequence $\{a(n)\}$ mentioned in the Abstract appears to be new, as do many of the other sequences we will discuss. We will also give new properties of some sequences that have been studied elsewhere.

Section 2 discusses the sequence mentioned in the Abstract, and also introduces the "square" of a sequence. Some simple generalizations (non-monotonic, "even" and "lying" versions) are described in Section 3. The original sequence is based on examination of the sequence modulo 2. In Section 4 we consider various "mod y" generalizations. Section 5 extends both the original sequence and the "mod y" generalizations by defining the "Aronson transform" of a sequence. Finally, Section 6 briefly considers the case when the rule defining the sequence depends on more than one term.

There are in fact a large number of possible generalizations and we mention only some of them here. We have not even analyzed all the sequences that we do mention. In some cases we just list the first few terms and invite the reader to investigate them himself. We give the identification numbers of these sequences in [12] — the entries there will be updated as more information becomes available.

We have also investigated sequences arising when (2) is replaced by the following rule: $s(1) = x, s(n) = s(n-1) + y$ if n is already in the sequence, $s(n) = s(n-1) + z$ otherwise, for specified values of x, y, z. This work will be described elsewhere [4].

Notation. "Sequence" here usually means an infinite sequence of nonnegative numbers. "Monotonically increasing" means that each term is strictly greater than the previous term. $\mathbb{P} = \{1, 2, 3, \ldots\}$, $\mathbb{N} = \{0, 1, 2, 3, \ldots\}$.

2. n is in the sequence if and only if $a(n)$ is odd

Let the sequence $a(1)$, $a(2)$, $a(3), \ldots$ be defined by the rule that $a(n)$ is the smallest positive integer $> a(n-1)$ which is consistent with the condition that

$$\text{"}n \text{ is a member of the sequence if and only if } a(n) \text{ is odd."} \tag{1}$$

The first term, $a(1)$, could be 1, since 1 is odd and 1 would be in the sequence. It could also be 2, since then 1 would not be in the sequence (because the terms must increase) and 2 is even. But we must take the *smallest* possible value, so $a(1) = 1$. Now $a(2)$ cannot be 2, because 2 is even. Nor can $a(2)$ be 3, for then 2 would not be in the sequence but $a(2)$ would be odd. However, $a(2) = 4$ is permissible, so we *must* take $a(2) = 4$, and then 2 and 3 are not in the sequence.

So $a(3)$ must be even and > 4, and $a(3) = 6$ works. Now 4 is in the sequence, so $a(4)$ must be odd, and $a(4) = 7$ works. Continuing in this way we find that the first few

terms are as follows (this is A79000):

n :	1	2	3	4	5	6	7	8	9	10	11	12	$\cdots$
$a(n)$:	1	4	6	7	8	9	11	13	15	16	17	18	$\cdots$

Once we are past $a(2)$ there are no further complications, $a(n-1)$ is greater than n, and we *can*, and therefore *must*, take

$$a(n) = a(n-1) + \epsilon \ , \tag{2}$$

where ϵ is 1 or 2 and is given by:

	$a(n-1)$ even	$a(n-1)$ odd
n in sequence	1	2
n not in sequence	2	1

The gap between successive terms for $n \geq 3$ is either 1 or 2.

The analogy with Aronson's sequence is clear. Just as Aronson's sentence indicates exactly which of its terms are t's, $\{a(n)\}$ indicates exactly which of its terms are odd.

We proceed to analyze the behavior of this sequence.

First, all odd numbers ≥ 7 occur. For suppose $2t+1$ is missing. Therefore $a(i) = 2t$, $a(i+1) = 2t+2$ for some $i \geq 3$. From the definition, this means i and $i+1$ are missing, implying a gap of at least 3, a contradiction.

Table I shows the first 72 terms, with the even numbers underlined.

Examining the table, we see that there are three consecutive numbers, 6, 7, 8, which are necessarily followed by three consecutive odd numbers, $a(6) = 9$, $a(7) = 11$, $a(8) = 13$. Thus 9 is present, 10 is missing, 11 is present, 12 is missing, and 13 is present. Therefore the sequence continues with $a(9) = 15$ (odd), $a(10) = 16$ (even), ..., $a(13) = 19$ (odd), $a(14) = 20$ (even). This behavior is repeated for ever. A run of consecutive numbers is immediately followed by a run of the same length of consecutive odd numbers.

Let us define the k^{th} segment (for $k \geq 0$) to consist of the terms $a(n)$ with $n = 9 \cdot 2^k - 3 + j$ where $-3 \cdot 2^k \leq j \leq 3 \cdot 2^k - 1$. In the table the segments are separated by vertical lines. The first half of each segment, the terms where $j < 0$, consists of consecutive numbers given by $a(n) = 12 \cdot 2^k - 3 + j$; the second half, where $j \geq 0$, consists of consecutive odd numbers given by $a(n) = 12 \cdot 2^k - 3 + 2j$. We can combine these formulae, obtaining an explicit description for the sequence:

$$a(1) = 1, \quad a(2) = 4,$$

and subsequent terms are given by

$$a(9 \cdot 2^k - 3 + j) = 12 \cdot 2^k - 3 + \frac{3}{2}j + \frac{1}{2}|j| \tag{3}$$

for $k \geq 0$, $-3 \cdot 2^k \leq j < 3 \cdot 2^k$.

The structure of this sequence is further revealed by examining the sequence of first differences, $\Delta a(n) = a(n+1) - a(n)$, $n \geq 1$, which is

$$3, 2, 1, 1, 1, 2, 2, 2, 1^6, 2^6, 1^{12}, 2^{12}, 1^{24}, 2^{24}, \ldots \tag{4}$$

$n:$	1	2	3	4	5	6	7	8	9	10
$a(n):$	1	4	6	7	8	9	11	13	15	16
$n:$	11	12	13	14	15	16	17	18	19	20
$a(n):$	17	18	19	20	21	23	25	27	29	31
$n:$	21	22	23	24	25	26	27	28	29	30
$a(n):$	33	34	35	36	37	38	39	40	41	42
$n:$	31	32	33	34	35	36	37	38	39	40
$a(n):$	43	44	45	47	49	51	53	55	57	59
$n:$	41	42	43	44	45	46	47	48	49	50
$a(n):$	61	63	65	67	69	70	71	72	73	74
$n:$	51	52	53	54	55	56	57	58	59	60
$a(n):$	75	76	77	78	79	80	81	82	83	84
$n:$	61	62	63	64	65	66	67	68	69	70
$a(n):$	85	86	87	88	89	90	91	92	93	95
$n:$	71	72	$\cdots$							
$a(n):$	97	99	$\cdots$							

Table I: The first 72 terms of the sequence "n is in the sequence if and only if $a(n)$ is odd."

(A79948), where we have written 1^m to indicate a string of m 1's, etc. The oscillations double in length at each step.

Segment 0 begins with an even number, 6, but all other segments begin with an odd number, $9 \cdot 2^k - 3$. All odd numbers occur in the sequence except 3 and 5. The even numbers that occur are 4, 6, 8 and all numbers $2m$ with

$$9 \cdot 2^{k-1} - 1 \le m \le 6 \cdot 2^k - 2, \quad k \ge 1\,.$$

The sequence of differences, (4), can be constructed from the words in a certain formal language (cf. [11]). Let the alphabet be $\mathcal{A} = \{1, 2, 3\}$, and let $\mathcal{A}^*$ denote the set of strings of elements from $\mathcal{A}$. We define a mapping θ from $\mathcal{A}^*$ to $\mathcal{A}^*$ by the rules $\theta(1) = 2, \theta(2) = 1, 1$. Then (4) is the concatenation

$$S_{-1}, S_0, S_1, S_2, \ldots\,, \tag{5}$$

where

$$S_{-1} = \{3, 2\},\ S_0 = \{1, 1, 1\},\ S_{k+1} = \theta(S_k) \text{ for } k \ge 0\,. \tag{6}$$

To prove this, note that for $n \ge 3$, a difference of 2 only occurs in $\{a(n)\}$ between a pair of odd numbers. Suppose $a(i) = 2j + 1, a(i + 1) = 2j + 3$; then $a(2j + 1) = 2x + 1$ (say),

$a(2j+2) = 2x+2, a(2j+3) = 2x+3$, producing two differences of 1. Similarly, if there is a difference of 1, say $a(i) = j, a(i+1) = j+1$, then $a(j) = 2x+1, a(j+1) = 2x+3$, a difference of 2.

The ratio $n/a(n)$, which is the fraction of positive integers in the sequence that are less than or equal to $a(n)$, rises from close to 2/3 at the beginning of segment k (assuming k is large), reaches a maximum 3/4 at the midpoint of the segment, then falls back to 2/3 at the end of the segment. It is not difficult to show that if n is chosen at random in the k^{th} segment then the average value of the fraction of numbers in the sequence at that point approaches

$$\frac{3}{4} - \frac{1}{4}\log\frac{32}{27} = 0.7075\ldots$$

for large k.

The sequence has an alternative characterization in terms of its "square."

The *square* of a sequence $\mathbf{s} = \{s(n) : n \geq n_0\}$ is given by $\mathbf{s}^{(2)} = \{s(s(n)) : n \geq n_0\}$. If $\mathbf{s}$ is monotonically increasing so is $\mathbf{s}^{(2)}$.

Lemma 1. *Let* $\mathbf{s}$ *be monotonically increasing. Then* n $(\geq n_0)$ *is in the sequence* $\mathbf{s}$ *if and only if* $s(n)$ *is in the sequence* $\mathbf{s}^{(2)}$.

Proof. If n is in the sequence, $n = s(i)$ for some $i \geq n_0$, and $s(n) = s(s(i))$ is in $\mathbf{s}^{(2)}$. Conversely, if $s(n) \in \mathbf{s}^{(2)}$, $s(n) = s(s(i))$ for some $i \geq n_0$, and since $\mathbf{s}$ is monotonically increasing, $n = s(i)$. ∎

For our sequence $\mathbf{a} = \{a(n)\}$, examination of Table I shows that $\mathbf{a}^{(2)} = \{1, 5, 7, 9, 11, \ldots\} = \{1\} \cup 2\mathbb{P} + 3$. This can be used to characterize $\mathbf{a}$. More precisely, the sequence can be defined by: $a(1) = 1$, $a(2) = 4$, $a(3) = 6$ and, for $n \geq 4$, $a(n)$ is the smallest positive integer which is consistent with the sequence being monotonically increasing and satisfying $a(a(n)) = 2n + 3$ for $n \geq 2$.

This is easily checked. Once the first three terms are specified, the rule $a(a(n)) = 2n + 3$ determines the remaining terms uniquely.

In fact that rule also forces $a(2)$ to be 4, but it does not determine $a(3)$, since there is an earlier sequence $\{a'(n)\}$ (in the lexicographic sense) satisfying $a'(1) = 1$, $a'(a'(n)) = 2n + 3$ for $n \geq 2$, namely

$$1, 4, 5, 7, 9, 10, 11, 12, 13, 15, 17, 19, 21, 22, \ldots,$$

(A80596), and given by $a'(1) = 1$,

$$a'(6 \cdot 2^k - 3 + j) = 8 \cdot 2^k - 3 + \frac{3}{2}j + \frac{1}{2}|j| \tag{7}$$

for $k \geq 0$, $-2^{k+1} \leq j < 2^{k+1}$.

As the above examples show, the square of a sequence does not in general determine the sequence uniquely. A better way to do this is provided by the "inverse Aronson transform", discussed in Section 5.

3. First generalizations

The properties of $\{a(n)\}$ given in Section 2 suggest many generalizations, some of which will be discussed in this and the following sections.

(3.1) Non-monotonic version. If we replace "$a(n) > a(n-1)$" in the definition by "$a(n)$ is not already in the sequence", we obtain a completely different sequence, suggested by J. C. Lagarias [10]: $b(n)$, $n \geq 1$, is the smallest positive integer not already in the sequence which is consistent with the condition that "n is a member of the sequence if and only if $b(n)$ is odd." This sequence (A79313) begins:

n:	1	2	3	4	5	6	7	8	9	10
$b(n)$:	1	3	5	2	7	8	9	11	13	12

n:	11	12	13	14	15	16	17	18	19	20
$b(n)$:	15	17	19	16	21	23	25	20	27	29

The even members are underlined. The behavior is simpler than that of $\{a(n)\}$, and we leave it to the reader to show that, for $n \geq 5$, $b(n)$ is given by

$$\begin{aligned} b(4t-2) &= 4t\,, \\ b(4t-1) &= 6t-3\,, \\ b(4t) &= 6t-1\,, \\ b(4t+1) &= 6t+1\,. \end{aligned}$$

All odd numbers occur. The only even numbers are 2 and $4t$, $t \geq 2$. (The square $\mathbf{b}^{(2)}$ is not so interesting.)

(3.2) "Even" version. If instead we change "odd" in the definition of $\{a(n)\}$ to "even", we obtain a sequence $\mathbf{c}$ which is best started at $n = 0$: $c(n)$, $n \geq 0$, is the smallest nonnegative integer $> c(n-1)$ which is consistent with the condition that

"n is a member of the sequence if and only if $c(n)$ is even." (8)

This is A79253: 0, 3, 5, 6, 7, 8, 10, 12, 14, 15, ... It is easily seen that $c(n) = a(n+1)-1$ for $n \geq 0$, so there is nothing essentially new here. Also $\mathbf{c}^{(2)} = \{0\} \cup 2\mathbb{P} + 4$.

(3.3) The "lying" version. The lying version of Aronson's sequence is based on the completely false sentence "t is the second, third, fifth, sixth, seventh, ... letter of this sentence." The sentence specifies exactly those letters that are not t's, and produces the sequence (A81023) 2, 3, 5, 6, 7, 8, 9, 10, 11, 12, ...

Just as $\{a(n)\}$ is an analogue of Aronson's sequence, we can define an analogue $\{d(n) : n \geq 1\}$ of this sequence by saying that: $d(n)$ is the smallest positive integer $> d(n-1)$ such that the condition "n is in the sequence if and only if $d(n)$ is odd" is false. Equivalently, the condition "either n is in the sequence and $d(n)$ is even or n is

not in the sequence and $d(n)$ is odd" should be true. The resulting sequence (A80653) begins 2, 4, 5, 6, 8, 10, 11, 12, 13, 14, ... We will give an explicit formula for $d(n)$ in the next section.

A related sequence is also of interest. Let $\{d'(n)\}$ be defined by $d'(1) = 2$, and, for $n > 1$, $d'(n)$ is the smallest integer greater than $d'(n-1)$ such that the condition "n and $d'(d'(n))$ have opposite parities" can always be satisfied. One can show that this is the sequence

$$2, 4, 5, 7, 8, 9, 11, 12, 13, 14, 16, \ldots$$

(A14132), the complement of the triangular numbers (A217), with $d'(n) = n +$ (nearest integer to $\sqrt{2n}$).

4. The "mod m" versions

Both $\{a(n)\}$ and $\{c(n)\}$ are defined modulo 2. Another family of generalizations is based on replacing 2 by some fixed integer $y \geq 2$. To this end we define a sequence $\{s(n) : n \geq n_0\}$ by specifying a starting value $s(n_0) = s_0$, and the condition that n is in the sequence if and only if $s(n) \equiv z \pmod{y}$, where y and z are given.

Although we will not digress to consider this here, it is also of interest to see what happens when "if and only if" in the definition is replaced by either "if" or "only if." (We mention just one example. The above sequence $\{d(n)\}$, prefixed by $d(0) = 0$, can be defined as follows: $d(n)$ is the smallest nonnegative number $> d(n-1)$ such that the condition "n ($n \geq 0$) is in the sequence only if $d(n)$ is even" is satisfied.)

We saw in the previous section that $\{a(n)\}$ can also be characterized by the property that its square $a^{(2)}(n) = a(a(n))$ is equal to $2n+3$ for $n \geq 2$ (together with some appropriate initial conditions). This too can be generalized by specifying that the sequence $\{s(n)\}$ satisfy $s(s(n)) = yn + z$, for given values of y and z. The two generalizations are related, but usually lead to different sequences. The $s(s(n))$ family of generalizations will connect the present investigation with several sequences that have already appeared in the literature. There are too many possibilities for us to give a complete catalogue of all the sequences that can be obtained from these generalizations. Instead we will give a few key examples and one general theorem. Many other examples can be found in [12].

A simple "mod 3" generalization is: $e(1) = 2$, and, for $n > 1$, $e(n)$ is the smallest integer $> e(n-1)$ which is consistent with the condition that

$$\text{"}n \text{ is a member of the sequence if and only if } e(n) \text{ is a multiple of 3."} \qquad (9)$$

This turns out to be James Propp's sequence

$$2, 3, 6, 7, 8, 9, 12, 15, 18, 19, \ldots ,$$

which appeared as sequence M0747 in [13] (A3605 in [12]). Propp gave a different (although equivalent) definition involving the square of the sequence: $\{e(n)\}$ is the unique monotonically increasing sequence satisfying $e(e(n)) = 3n$ for all $n \geq 1$. Michael

Somos [14] observed that this sequence satisfies

$$\begin{aligned} e(3n) &= 3e(n), \\ e(3n+1) &= 2e(n)+e(n+1), \\ e(3n+2) &= e(n)+2e(n+1). \end{aligned} \tag{10}$$

An analysis similar to that for $\{a(n)\}$ leads to the following explicit formula, which appears to be new:

$$e(2\cdot 3^k + j) = 3^{k+1} + 2j + |j|\,, \tag{11}$$

for $k \geq 0$ and $-3^k \leq j < 3^k$.

A sequence closely related to $\{e(n)\}$ had earlier been studied by Arkin et al. [2, Eq. (12)]. This is the sequence $e'(n) = e(n) - n$ (A6166). Arkin et al. give a recurrence similar to (10). The sequences defined by recurrences $s(s(n)) = kn$ for $k \geq 4$ have recently been studied by Allouche et al. [1].

The sequence $\{e(n)\}$ can be generalized as follows.

Theorem 2. *Let y and z be integers of opposite parity satisfying*

$$y \geq 2,\ \ z \geq 2-y\,. \tag{12}$$

Then there is a unique monotonically increasing sequence $\{f(n)\}$ satisfying $f(1) = \frac{1}{2}(y+z+1)$ and $f(f(n)) = yn+z$ for $n > 1$. It is given by

$$f\left(c_1 y^k - \frac{z}{y-1} + j\right) = c_2 y^{k+1} - \frac{z}{y-1} + \frac{y+1}{2}j + \frac{y-1}{2}|j|\,, \tag{13}$$

for $k \geq 0$, where

$$-\frac{y+z-1}{2}y^k \leq j < \frac{y+z-1}{2}y^k$$

and

$$c_1 = \frac{(y+1)(y+z-1)}{2(y-1)}, \quad c_2 = \frac{y+z-1}{y-1}\,.$$

Proof. It is easy to see that the sequence $\{s(n)\}$ defined by

$$s(n) \;=\; \frac{(y+1)n - 2f(n) + z}{y-1} \tag{14}$$

is a "saw-tooth" sequence of the form

$$0,1,2,3,\ldots,3,2,1,0,1,2,3,4,5,6,\ldots,6,5,4,3,2,1,0,1,2,3,\ldots\ ,$$

where the 0's occur at

$$n \;=\; 1 + \frac{(y+z-1)(y^k-1)}{y-1} \text{ for } k \geq 0\ .$$

Consequently the k-th "tooth" $0, 1, 2, 3, \ldots, 3, 2, 1, 0$ contains $(y+z-1)y^k$ terms and reaches a maximal value of $(y+z-1)y^k/2$. Then from simple considerations of symmetry, for any $k \geq 0$ and any j such that $|j| \leq (y+z-1)y^k/2$, we have

$$s\left(1 + \frac{(y+z-1)(y^k-1)}{y-1} + \frac{(y+z-1)y^k}{2} + j\right) \;=\; \frac{(y+z-1)}{2}y^k - |j| \;.$$

In other words,

$$s\left(\frac{(y+z-1)(y+1)}{2(y-1)}y^k - \frac{z}{y-1} + j\right) \;=\; \frac{(y+z-1)}{2}y^k - |j| \;. \tag{15}$$

Equation (13) follows from (14) and (15). ∎

It can be shown (we omit the details) that this sequence can also be defined by: $f(1) = (y+z+1)/2$, and, for $n > 1$, $f(n)$ is the smallest integer $> f(n-1)$ which is consistent with the condition that "n is a member of the sequence if and only if $f(n)$ belongs to the set

$$[2, \ldots, \frac{1}{2}(y+z-1)] \;\cup\; \{iy+z : i \geq 1\}\,."\tag{16}$$

If $(y+z-1)/2 \leq 1$, the first set in (16) is to be omitted.

Examples. Setting $y = 3$, $z = 0$ in the theorem produces $\{e(n)\}$.

Setting $y = 2$, $z = 1$ yields another interesting "mod 2" sequence. This is the sequence $\{g(n) : n \geq 1\}$ that begins

$$2, 3, 5, 6, 7, 9, 11, 12, 13, 14, \ldots$$

(A80637). It has the following properties:

(i) By definition, this is the unique monotonically increasing sequence $\{g(n)\}$ satisfying $g(1) = 2$, $g(g(n)) = 2n+1$ for $n \geq 2$.

(ii) n is in the sequence if and only if $g(n)$ is an odd number ≥ 3.

(iii) The sequence of first differences is (A79882):

$$1, 2, 1^2, 2^2, 1^4, 2^4, 1^8, 2^8, 1^{16}, 2^{16}, \ldots.$$

(iv)

$$g(3 \cdot 2^k - 1 + j) = 2 \cdot 2^{k+1} - 1 + \frac{3}{2}j + \frac{1}{2}|j|\,,$$

for $k \geq 0$, $-2^k \leq j < 2^k$ (from (13)).

(v) $g(2n) = g(n) + g(n-1) + 1$, $g(2n+1) = 2g(n) + 1$, for $n \geq 1$ (taking $g(0) = 0$).

(vi) The original sequence $\{a(n)\}$ satisfies $a(3n) = 3g(n), a(3n+1) = 2g(n) + g(n+1), a(3n+2) = g(n) + 2g(n+1)$, for $n \geq 1$.

(vii) The "lying version" of Section 3 is given by $d(n) = g(n+1) - 1$ for $n \geq 1$.

(viii) Let $g'(n) = g(n) + 1$. The sequence $\{g'(n) : n \geq 2\}$ was apparently first discovered by C. L. Mallows, and is sequence M2317 in [13] (A7378 in [12]). This is the unique monotonically increasing sequence satisfying $g'(g'(n)) = 2n$. An alternative

description is: $g'(n)$ (for $n \geq 2$) is the smallest positive integer $> g'(n-1)$ which is consistent with the condition that

"n is a member of the sequence if and only if $g'(n)$ is an even number ≥ 4". (17)

Note that, although (8) and (17) are similar, the resulting sequences $\{c(n)\}$ and $\{g'(n)\}$ are quite different. g' is not directly covered by Theorem 2, and we admit that we have not been able to identify the largest family of sequences which can be described by formulae like (3), (7), (11), (13).

The sequence $\{h(n)\}$ defined by: $h(1) = 2$, and, for $n > 1$, $h(n)$ is the smallest positive integer $> h(n-1)$ which is consistent with the condition that "n is a member of the sequence if and only if $h(n)$ is a multiple of 6":

$$2, 6, 7, 8, 9, 12, 18, 24, 30, 31, \ldots ,$$

(A80780), shows that such simple rules do not hold in general. We can characterize the sequence of first differences in a manner similar to (5), (6): the alphabet is now $\mathcal{A} = \{1, 2, \ldots, 6\}$, and we define a mapping θ from $\mathcal{A}^*$ to $\mathcal{A}^*$ by the rules $\theta(i) = 1, 1, \ldots, 1, 7-i$ (with $i-1$ 1's followed by $7-i$), for $i = 1, \ldots, 6$. Then the sequence of differences of $\{h(n)\}$ is $S_0, S_1, S_2, \ldots$, where $S_0 = \{4\}, S_{k+1} = \theta(S_k)$ for $k \geq 0$. However, it appears that no formula similar to (3) holds for $h(n)$.

We end this "mod m" section with two interesting "mod 4" sequences. The even numbers satisfy $s(s(n)) = 4n$, and the odd numbers satisfy $s(s(n)) = 4n+3$. But there are lexicographically earlier sequences with the same properties. The "pseudo-even numbers" $\{i(n) : n \geq 0\}$ are defined by the property that $i(n)$ is the smallest nonnegative integer $> i(n-1)$ and satisfying $i(i(n)) = 4n$ (A80588):

$$0, 2, 4, 5, 8, 12, 13, 14, 16, 17, \ldots$$

We analyze this sequence by describing the sequence of first differences, which are

$$2, 2, 1, 3, 4, 1, 1, 2, 1, 1, 1, 1, 4, 4, 1, 3, \ldots$$

After the initial 2, 2, 1, this breaks up into segments of the form

$$3\ S_k\ 2\ T_k\ ,$$

where T_k is the reversal of

$$1^1\ 4^2\ 1^4\ 4^8\ 1^{16}\ 4^{32} \cdots 4^{2^{2k-1}} 1^{2^{2k}}$$

and S_k is the reversal of

$$1^2\ 4^1\ 1^8\ 4^4\ 1^{32}\ 4^{16} \cdots 1^{2^{2k-1}} 4^{2^{2k-2}}\ .$$

The "pseudo-odd numbers", $i'(n)$, are similarly defined by $i'(i'(n)) = 4n+3$:

$$1, 3, 4, 7, 11, 12, 13, 15, 16, 17, \ldots$$

(A80591), and satisfy $i'(n) = i(n+1) - 1$.

5. The Aronson transform

A far-reaching generalization of both the original sequence and the "mod m" extensions of the previous section is obtained if we replace "odd number" in the definition of $\{a(n)\}$ by "member of $\boldsymbol{\beta}$", where $\boldsymbol{\beta}$ is some fixed sequence.

More precisely, let us fix a starting point n_0, which will normally be 0 or 1. Let $\boldsymbol{\beta} = \{\beta(n) : n \geq n_0\}$ be an infinite monotonically increasing sequence of integers $\geq n_0$ with the property that its complement (the numbers $\geq n_0$ that are not in $\boldsymbol{\beta}$) is also infinite. Then the sequence $\boldsymbol{\alpha} = \{\alpha(n) : n \geq n_0\}$ given by: $\alpha(n)$ is the smallest positive integer $> \alpha(n-1)$ which is consistent with the condition that

"n is in $\boldsymbol{\alpha}$ if and only if $\alpha(n)$ is in $\boldsymbol{\beta}$"

is called the *Aronson transform* of $\boldsymbol{\beta}$.

Theorem 3. *The Aronson transform exists and is unique.*

Proof. For ease of discussion let us call the numbers in $\boldsymbol{\beta}$ "hot", and those in its complement "cold." We will specify the transform $\boldsymbol{\alpha}$, leaving to the reader the easy verification that this has the desired properties, in particular that there are no contradictions.

The proof is by induction. First we consider the initial term $\alpha(n_0)$. If n_0 is hot, $\alpha(n_0) = n_0$. If n_0 is cold, $\alpha(n_0) =$ smallest cold number $\geq n_0 + 1$.

For the induction step, suppose $\alpha(n) = k$ for $n > n_0$.

Case (i), $k = n$. If $n+1$ is hot then $\alpha(n+1) = n+1$. If $n+1$ is cold then $\alpha(n+1) =$ smallest cold number $\geq n+2$.

Case (ii), $k > n$. If $k = n+1$ then $\alpha(n+1) =$ smallest hot number $\geq n+2$. If $k > n+1$ then if $n+1$ is hot, $\alpha(n+1) =$ smallest hot number $\geq k+1$, while if $n+1$ is cold, $\alpha(n+1) =$ smallest cold number $\geq k+1$. ∎

In certain cases it may be appropriate to specify some initial terms in $\boldsymbol{\alpha}$ to get it started properly.

Examples. Of course taking $\boldsymbol{\beta}$ to be the odd numbers (with $n_0 = 1$) leads to our original sequence $\{a(n)\}$, and the even numbers (with $n_0 = 0$) lead to $\{c(n)\}$ of Section 3.

If we take $\boldsymbol{\beta}$ to be the triangular numbers we get 1, 4, 5, 6, 10, 15, 16, 17, 18, 21, ... (A79257); the squares give 1, 3, 4, 9, 10, 11, 12, 13, 16, 25, ... (A79258); the primes give 4, 6, 8, 11, 12, 13, 14, 17, 18, 20, ... (A79254); and the lower Wythoff sequence (A201), in which the n^{th} term is $\lfloor n\phi \rfloor$, gives 1, 5, 7, 10, 11, 13, 14, 15, 18, 19, ... (A80760).

Taking the Aronson transform of $\{a(n)\}$ itself we get 1, 3, 4, 6, 10, 11, 12, 14, 22, 23, ... (A79325). [12] contains several other examples.

The inverse transform may be defined in a similar way. Given an infinite monotonically increasing sequence $\boldsymbol{\alpha} = \{\alpha(n) : n \geq n_0\}$ of numbers $\geq n_0$, such that its complement (the numbers $\geq n_0$ that are not in $\boldsymbol{\alpha}$) is also infinite, its *inverse Aronson transform* is the sequence $\boldsymbol{\beta} = \{\beta(n) : n \geq n_0\}$ such that the Aronson transform of $\boldsymbol{\beta}$ is $\boldsymbol{\alpha}$.

Theorem 4. *The inverse Aronson transform exists and is unique.*

Proof. We establish this by giving a simple algorithm to construct the inverse transform. We illustrate the algorithm in Table II by applying it to the sequence of squares, $\boldsymbol{\alpha} = \{n^2 : n \geq 0\}$.

Form a table with four rows. In the first row place the numbers $n = n_0$, $n_0 + 1$, $n_0 + 2, \ldots$, and in the second row place the sequence $\alpha(n_0)$, $\alpha(n_0 + 1), \ldots$. The third row contains what we will call the "hot" numbers: these will comprise the elements of the inverse transform. The fourth row are the "cold" numbers, which are the complement of the hot numbers.

The third and fourth rows are filled in as follows. If n is *in* (resp. *not in*) the sequence $\boldsymbol{\alpha}$, place $\alpha(n)$ in the n-th slot of the hot (resp. cold) row.

To complete the table we must fill in the empty slots. Suppose we are at column n, where we have placed $\alpha(n)$ in one of the two slots. Let l_n be the largest number mentioned in columns $n_0, \ldots, n-1$ in the hot or cold rows. Then we place the numbers $l_n + 1, \ldots, \alpha(n) - 1$ in the empty slot in column n, with the single exception that if n is not in the sequence and $l_n = n - 1$ then we place n in the cold slot rather than the hot slot. (This is illustrated by the position of 2 in the fourth row of Table II.) We leave it to the reader to verify that the entries in the "hot" row form the inverse Aronson transform $\boldsymbol{\beta}$. ∎

n	1	2	3	4	5	6	7	8	9
α_n	1	4	9	16	25	26	49	64	81
"hot"	1	3	5–8	16	17–24	26–35	37–48	50–63	81
"cold"	–	2, 4	9	10–15	25	36	49	64	65–80

Table II: Computation of the inverse Aronson transform of the squares. The "hot" numbers comprise the transform.

It follows from Lemma 1 that $\boldsymbol{\beta}$ contains the members of $\boldsymbol{\alpha}^{(2)}$, but in general $\boldsymbol{\beta} \neq \boldsymbol{\alpha}^{(2)}$. The additional terms in $\boldsymbol{\beta}$ make it possible to recover $\boldsymbol{\alpha}$ uniquely from $\boldsymbol{\beta}$.

Examples. As shown in Table II, the inverse Aronson transform of the squares (A10906) is

$$1; 3; 5, 6, 7, 8; 16; 17, \ldots, 24; 26, 27, \ldots .$$

This consists of a number of segments (separated here by semicolons). For $k \geq 1$ the k^{th} segment is $\{k^2\}$ if k is a square, or $\{(k-1)^2 + 1, \ldots, k^2 - 1\}$ if k is not a square, except that the second segment $= \{3\}$.

The inverse transform of the primes is 3, 5, 6, 11, 12, 17, 18, 20, 21, 22, ... (A80759) — this has a similar decomposition into segments.

The inverse transform of the lower Wythoff sequence is 1, 4, 6, 7, 9, 10, 12, 14, 15, 17, ... (A80746). This consists of the numbers $\lfloor \phi k \rfloor + k - 1$ $(k \geq 1)$ and $\lfloor 2\phi k \rfloor + k - 1$ $(k \geq 2)$. The inverse transform of our original sequence $\{a(n)\}$ is the sequence of odd numbers (whereas, as we saw in Section 2, $a^{(2)}$ omits 3).

In general (because of the above algorithm), the inverse Aronson transforms are easier to describe than the direct transforms.

6. More complicated conditions

Finally, we may make the condition for n to be in the sequence depend on the values of several consecutive terms $a(n)$, $a(n+1), \ldots, a(n+\tau)$, for some fixed τ. To pursue this further would take us into the realm of one-dimensional cellular automata (cf. [9], [15]), and we will mention just two examples.

$q(n)$ is the smallest positive integer $> q(n-1)$ which is consistent with the condition that "n is in the sequence if and only if $q(n)$ is odd and $q(n-1)$ is even" (A79255):

$$1, 4, 6, 9, 12, 15, 18, 20, 23, 26, 28, \ldots$$

The gaps between successive terms are always 2 or 3. Changing the condition to "... both $q(n)$ and $q(n+1)$ are odd" gives A79259:

$$1, 5, 6, 10, 11, 15, 19, 20, 24, 25, \ldots$$

Abstract

A composition of a positive integer n consists of an ordered sequence of positive integers whose sum is n. We investigate compositions in which the summand 2 is not allowed, and count the total number of such compositions and the number of occurrences of the summand i in all such compositions. Furthermore, we explore patterns in the values for $C_j(n, \hat{2})$, the number of compositions of n without 2's having j summands, and show connections to several known sequences, for example the n-dimensional partitions of 4 and 5.

1 Introduction

Adding whole numbers seems like one of the most basic ideas in all of mathematics, but many unanswered questions remain within this area of combinatorial number theory. A

broad class of questions relate to compositions and partitions. A *composition* of n is an ordered collection of one or more positive integers for which the sum is n. The number of summands is called the number of *parts* of the composition. A *palindromic composition* or *palindrome* is one for which the sequence is the same from left to right as from right to left. A *partition* of n is an unordered collection of one or more positive integers whose sum is n.

Compositions may also be viewed as *tilings* of a 1-by-n board with 1-by-k tiles, $1 \leq k \leq n$. Figure 1 shows the compositions of 3 together with corresponding tilings of the 1-by-3 board using 1-by-1, 1-by-2 and 1-by-3 tiles.

Figure 1: The compositions of 3 and their corresponding tilings

In this view, a palindromic composition corresponds to a symmetric tiling, e.g., the tilings corresponding to 1+1+1 and 3 in Figure 1. One reason to adopt the tiling viewpoint for compositions is that some counting questions about compositions arise more naturally in the context of tilings. More examples of the interrelation between compositions and tilings can be found in [4, 5, 6, 7, 9].

In [9], Grimaldi explores the question of how many compositions of n exist when no 1's are allowed in the composition. In this paper we explore a related question, namely, how many compositions of n exist when no 2's are allowed in the composition. We also look at how many of these compositions are palindromes.

We count the total number of compositions and explore patterns involving the number of compositions with a fixed number of parts and the total number of occurrences of each positive integer among all the compositions of n without occurrences of 2. In the viewpoint of tilings, these questions correspond to counting the total number of tilings, the number of tilings with a fixed number of tiles and the number of times a tile of a particular size occurs among all the tilings of the 1-by-n board that do not contain any 1-by-2 tiles. Next, we count the number of palindromes of n without any occurrence of 2, which correspond to symmetric tilings with no 1-by-2 tiles. Finally, we give a table of values for the number of partitions of n that do not contain any occurrence of 2. We use the following notation:

$$
\begin{aligned}
C(n, \hat{2}) &= \text{the number of compositions of } n \text{ with no 2's} \\
C_j(n, \hat{2}) &= \text{the number of compositions of } n \text{ with no 2's having exactly } j \text{ parts} \\
x(n, i, \hat{2}) &= \text{the number of occurrences of } i \text{ among all compositions of } n \text{ with no 2's} \\
P(n, \hat{2}) &= \text{the number of palindromes of } n \text{ with no 2's} \\
\pi(n, \hat{2}) &= \text{the number of partitions of } n \text{ with no 2's.}
\end{aligned}
$$

Because we consider only compositions and palindromes of n with no 2's in this paper, we sometimes leave out the qualifier "with no occurrence of 2's".

2 The number of compositions without 2's

We start by counting the total number of compositions.

Theorem 1 *The number of compositions without occurrence of 2's is given by*

$$C(n,\hat{2}) = 2\cdot C(n-1,\hat{2}) - C(n-2,\hat{2}) + C(n-3,\hat{2})$$

with initial conditions $C(0,\hat{2}) = C(1,\hat{2}) = C(2,\hat{2}) = 1$*, and generating function*

$$G_C(z) = \sum_{n=0}^{\infty} C(n,\hat{2})z^n = \frac{1-z}{1-2z+z^2-z^3}\ .$$

Proof. The compositions of n without 2's can be generated recursively from those of $n-1$ by either appending a 1 or by increasing the last summand by 1. However, this process does not generate those compositions ending in 3, which we generate separately by appending a 3 to the compositions of $n-3$. Furthermore, we must delete the compositions of $n-1$ that end in 1, since increasing the terminal 1 would produce a composition of n that ends in 2. The number of such compositions corresponds to the number of compositions of $n-2$. The generating function $G_C(z)$ is computed by multiplying each term in the recurrence relation by z^n, and summing over $n \geq 3$. Expressing the resulting series in terms of $G_C(z)$ and solving for $G_C(z)$ gives the result. ∎

The following table gives some values of $C(n,\hat{2})$:

n	0	1	2	3	4	5	6	7	8	9	10	11	12
$C(n,\hat{2})$	1	1	1	2	4	7	12	21	37	65	114	200	351

Table 1: The number of compositions with no occurrence of 2

The sequence $C(n,\hat{2})$ appears as A005251 in Sloane's On-Line Encyclopedia of Integer Sequences [10], with representation $a(n) = a(n-1) + a(n-2) + a(n-4)$. Two alternative formulas are given for this sequence:

$$a(n) \quad = \quad 2\cdot a(n-1) - a(n-2) + a(n-3) \tag{1}$$

and

$$a(n) \quad = \quad \sum_{j<n} a(j) - a(n-2). \tag{2}$$

Eq. (1) is identical to the expression for $C(n,\hat{2})$ in Theorem 1, while Eq. (2) indicates a second way to create all the compositions with no 2's, namely, to append the summand j to a composition of $n-j$, except when $j=2$. Comparison of the initial conditions $(a(0)=0,\ a(1)=a(2)=a(3)=1)$ shows that $C(n,\hat{2}) = a(n+1)$.

One interpretation of sequence A005251 is the number of binary sequences without isolated 1's [2]. There is a nice combinatorial explanation for the equality of the two different counts, namely, the number of compositions of n without 2's and the number of binary sequences of n-1 without isolated 1's. Think of the composition as a tiling of the 1-by-n board. Associate a binary sequence of length n-1 with the interior places where a tile can start or end. If the binary sequence has a 0 in position k, then a tile ends or starts at position k, whereas a 1 indicates that the tile "continues". With this interpretation, isolated 1's, which appear as $\ldots 010 \ldots$ correspond to a 1-by-2 tile, as illustrated in Figure 2.

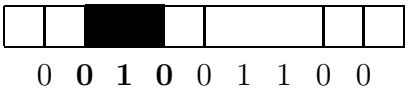

Figure 2: Correspondence of binary sequences and compositions

3 The number of occurrences of the summand i in all compositions with no 2's

Table 2 gives values of $x(n, i, \hat{2})$ for $1 \leq n \leq 10$ and $1 \leq i \leq 10$. We note that the entries in the columns appear to repeat. Theorem 2 shows that this repetition indeed continues.

	$i=1$	2	3	4	5	6	7	8	9	10
$n=1$	1									
2	2	0								
3	3	0	1							
4	6	0	2	1						
5	13	0	3	2	1					
6	26	0	6	3	2	1				
7	50	0	13	6	3	2	1			
8	96	0	26	13	6	3	2	1		
9	184	0	50	26	13	6	3	2	1	
10	350	0	96	50	26	13	6	3	2	1

Table 2: The number of occurrences of i among all compositions of n

Theorem 2 $x(n, i, \hat{2}) = x(n + j, i + j, \hat{2})$ *for all* $i \neq 2$, $i + j \neq 2$.

Proof. Consider any occurrence of the summand i among the compositions of n without 2's. There is a corresponding occurrence of $i + j$ in a composition of $n + j$ in which the summand i has been replaced by $i + j$ and all other summands are the same, as long as

$i + j \neq 2$. This correspondence is actually one-to-one since any occurrence of $i + j$ among the compositions of $n + j$ corresponds to an occurrence of i among the compositions of n obtained by replacing $i + j$ by i, subject to the condition that $i \neq 2$. ∎

As a result of Theorem 2, we only need to generate the first column of Table 2, namely the number of occurrences of 1 among all the compositions of n without 2's, a sequence not previously listed in Sloane's On-Line Encyclopedia of Integer Sequences [10]. We will give three different ways to generate this sequence.

Theorem 3 *The number of occurrences of 1 among all compositions of n without 2's is given by*

$$\begin{aligned} x(n,1,\hat{2}) &= 2\cdot x(n-1,1,\hat{2}) - x(n-2,1,\hat{2}) + x(n-3,1,\hat{2}) \\ &\quad + C(n-1,\hat{2}) - C(n-2,\hat{2}) \end{aligned} \tag{3}$$

with initial conditions $x(n,1,\hat{2}) = n$ for $n = 1,2,3$, or by

$$x(n,1,\hat{2}) = n\cdot C(n,\hat{2}) - \sum_{i=1}^{n-2}(n-i+1)\cdot x(i,1,\hat{2}). \tag{4}$$

The generating function $G_x(z) = \sum_{n=1}^{\infty} x(n,1,\hat{2})z^n$ is given by

$$G_x(z) = \frac{z(1-z)^2}{(1-2z+z^2-z^3)^2} = zG_C(z)^2, \tag{5}$$

thus, $x(n,1,\hat{2}) = \sum_{i=0}^{n-1} C(i,\hat{2})C(n-1-i,\hat{2})$.

Proof. Eq. (3) is based on the creation of the compositions of n from those of $n-1$ by either adding a 1 or by increasing the rightmost summand by 1. When adding a 1, we get all the "old" 1's, and for each composition an additional 1, altogether $x(n-1,1,\hat{2}) + C(n-2,\hat{2})$ 1's. When increasing the rightmost summand by 1, again we get all the "old" 1's (of which there are $x(n-1,1,\hat{2})$), except that we need to make adjustments for those compositions of $n-1$ with terminal summand 1, since they would result in a forbidden 2, and the otherwise missing compositions of n that end in 3. The latter have $x(n-3,1,\hat{2})$ 1's, which need to be added to the total count, while the 1's in the compositions of $n-1$ with a terminal 1 need to be subtracted. To determine how many of these 1's there are, we look at the composition of $n-1$ as consisting of a composition of $n-2$ and the terminal 1, i.e., we distinguish between "interior" 1's (those to the left of the terminal 1) and the terminal 1. The interior 1's correspond to all the 1's in the compositions of $n-2$. In addition, there is one terminal 1 for each composition of $n-2$. Thus, we subtract a total of $x(n-2,1,\hat{2}) + C(n-2,\hat{2})$ 1's from the total count. Simplification gives the stated result.

The derivation of Eq. (4) is based on a geometric argument involving all tilings of a 1-by-n board. The total area of all these tilings, given by $n\cdot C(n,\hat{2})$, has to equal the sum of the areas covered by 1-by-1, 1-by-2,..., and 1-by-n tiles. The area covered by 1-by-k tiles

is given by $k \cdot x(n,k,\hat{2})$, and thus, $n \cdot C(n,\hat{2}) = \sum_{k=1}^{n} k \cdot x(n,k,\hat{2})$. Since $x(n,2,\hat{2}) = 0$, we can rewrite this equation as

$$x(n,1,\hat{2}) \;\; = \;\; n \cdot C(n,\hat{2}) - \sum_{k=3}^{n} k \cdot x(n,k,\hat{2}). \tag{6}$$

Note that Eq. (6) relates the first entry in any row of Table 2 to all the other entries in the same row, which in turn show up in column 1 in "reverse" order: the rightmost non-zero element in any row equals the first element in column 1, the second element from the right in any row equals the second element in column 1, etc. We can formalize this association using the formula given in Theorem 2 (for $i = 1$): $x(m,1,\hat{2}) = x(m+j, j+1, \hat{2})$. We now choose m and j so that we get the terms that appear on the right-hand side of Eq. (6). This requires that $k = j+1$ and $n = m+j$, so using $m = n-k+1$ results in $x(n-k+1,1,\hat{2}) = x(n,k,\hat{2})$. Substituting this equality into Eq. (6) and reindexing gives the second recurrence relation for $x(n,1,\hat{2})$. Finally, the generating function $G_x(z)$ is computed as in the proof of Theorem 1, except that we now sum over $n \geq 4$ and express the resulting series in terms of $G_x(z)$ and $G_C(z)$. Note that the last equality in Eq. (5) indicates that the terms for the sequence $\{x(n,1,\hat{2})\}$ are a convolution of those of the sequence $\{C(n,\hat{2})\}$, with the index shifted by 1. The formula for $x(n,1,\hat{2})$ in terms of the $C(i,\hat{2})$ follows immediately from this observation. ■

4 The number of compositions without 2's having a given number of parts

Another question one can ask about compositions is how many of them have a given numbers of parts, i.e., a given number of summands. Table 3 gives the number of compositions of n without 2's that have j parts.

The values in Table 3 are generated using the recursion given in Theorem 4, which relates the entries in the j^{th} column to those in the $(j-1)^{st}$ column.

Theorem 4 $\quad C_j(n,\hat{2}) = \sum_{k=1}^{n-1} C_{j-1}(n-k,\hat{2}) - C_{j-1}(n-2,\hat{2})$.

Proof. For any composition of $n-k$ having $j-1$ parts, we can form a composition of n having j parts by adding the summand k to the end of the smaller composition, except for $k = 2$. This increases the number of parts by one as required. ■

We will now look at the patterns in the columns and diagonals of Table 3. The patterns in the left two columns clearly continue, since they correspond, respectively, to the single composition with one part, namely n, and the $n-3$ ways (for $n > 4$) to add two numbers (without using a 2) to get n. None of the remaining columns in Table 3 show any obvious pattern and they do not (yet) occur in [10].

Unlike the columns, the diagonals contain a rich set of patterns and show many connections to known integer sequences. For the entry in row n and column j in the k^{th} diagonal, we have $n - j = k - 1$, and thus the entries in the k^{th} diagonal are given by

	$j=1$	2	3	4	5	6	7	8	9	10	11
$n=1$	1										
2	0	1									
3	1	0	1								
4	1	2	0	1							
5	1	2	3	0	1						
6	1	3	3	4	0	1					
7	1	4	6	4	5	0	1				
8	1	5	9	10	5	6	0	1			
9	1	6	13	16	15	6	7	0	1		
10	1	7	18	26	25	21	7	8	0	1	
11	1	8	24	40	45	36	28	8	9	0	1
12	1	9	31	59	75	71	49	36	9	10	0
13	1	10	39	84	120	126	105	64	45	10	11
14	1	11	48	116	185	216	196	148	81	55	11
15	1	12	58	156	276	356	357	288	201	100	66
16	1	13	69	205	400	567	623	554	405	265	121
17	1	14	81	264	565	876	1050	1016	819	550	341

Table 3: The number of compositions of n with j parts

$C_j(n,\hat{2}) = C_j(j+k-1,\hat{2})$. We will look at the possible compositions of n having j parts by creating a composition of $n = j+k-1$ as follows: we start with j 1's (as there are to be j parts), and then distribute the difference $n-j = k-1$ across these j parts, adding to the 1's that are already there, as illustrated in the following example. Consider the compositions of $n = 4$ having $j = 2$ parts which can be generated as follows: first create two 1's, resulting in the composition 1+1. Then distribute the difference $n - j = 2$, i.e., consider all the partitions of 2, namely $\{2\}$ and $\{1,1\}$. Using the first partition leads to 3+1 (the first 1 is increased by 2) or 1+3 (the second 1 is increased by 2), and the second partition creates 2+2 (both 1's are increased by 1). The latter composition is not allowed as it contains 2's, so we have to disregard all the partitions of $n-j$ that contain a 1.

Now we can look at the diagonals in general, using this method to create and count the compositions of n having a given number of parts.

Theorem 5 *1.* $C_j(j,\hat{2}) = 1$ *(first diagonal)*
2. $C_j(j+1,\hat{2}) = 0$ *(second diagonal)*
3. $C_j(j+2,\hat{2}) = C_j(j+3,\hat{2}) = j$ *(third and fourth diagonals).*

Proof. The first diagonal corresponds to the compositions of all 1's, the only way to have n parts in a composition of n. For the second diagonal, $k = 2$ and thus $n-j = 1$. The only partition of 1 is itself, but this partition has to be excluded, so there are no compositions of n (without 2's) having $n-1$ parts. On the third diagonal, $k = 3$ and $n-j = 2$. This is exactly the example described above (for $j = 2$). Thus, the only partition for distributing

the difference between n and j is the single 2. Since there are j parts, there are exactly j possible compositions (with a single 3 and $j-1$ 1's). For the fourth diagonal, a similar argument applies, as the only partition of 3 without 1's is the single 3, so there are again j possible compositions (with a single 4 and $j-1$ 1's). ■

The next few diagonals contain more interesting sequences.

Theorem 6 *1.* $C_j(j+4,\hat{2}) = j(j+1)/2$*, i.e., the triangle numbers occur in the fifth diagonal.*
2. $C_j(j+5,\hat{2}) = j^2$*, i.e., the square numbers occur in the sixth diagonal.*

Proof. For $k=5$, we need to distribute $n-j=4$. The partitions of 4 that do not contain a 1 are $\{4\}$ and $\{2,2\}$. There are j ways to place the additional 4 and $j(j-1)/2$ ways to allocate the two 2's. Thus, $C_j(j+4,\hat{2}) = j + j(j-1)/2 = j(j+1)/2$. For $k=6$, we need to distribute $n-j=5$. The partitions of 5 that do not contain a 1 are $\{5\}$ and $\{3,2\}$, and there are j possibilities for the first partition and $j(j-1)$ for the second. Altogether, we have $C_j(j+5,\hat{2}) = j + j(j-1) = j^2$. ■

Theorem 7 *The seventh diagonal contains the n-dimensional partitions of 4.*

Proof. For $k=7$, we need to distribute $n-j=6$. The partitions of 6 that do not contain a 1 are $\{6\}$, $\{4,2\}$, $\{3,3\}$ and $\{2,2,2\}$. There are j compositions for the first partition, $j(j-1)$ for the second, $j(j-1)/2$ for the third, and $j(j-1)(j-2)/6$ for the fourth. Adding these terms and simplifying shows that

$$C_j(j+6,\hat{2}) = j(j^2+6j-1)/6.$$

The sequence $C_j(j+6,\hat{2})$ appears as A008778 in Sloane's On-Line Encyclopedia of Integer Sequences [10]. A008778 is defined by

$$a(n) = (n+1)(n^2+8n+6)/6$$

and counts the n-dimensional partitions of 4 (for a definition see [1], p. 179). We need to show the equivalence of the sequences $a(n)$ and $C_j(j+6,\hat{2})$ for a suitable value of n. The formulas for these two sequences suggest that $C_j(j+6,\hat{2}) = a(j-1)$, which can be confirmed by basic algebraic manipulations. ■

Theorem 8 *The eighth diagonal contains the pentagonal pyramidal numbers.*

Proof. For $k=8$, we need to distribute $n-j=7$. The partitions of 7 that do not contain a 1 are $\{7\}$, $\{5,2\}$, $\{4,3\}$ and $\{3,2,2\}$. These correspond, respectively, to the following number of compositions: j, $j(j-1)$, $j(j-1)$, and $j(j-1)(j-2)/2$. Adding these terms and simplifying shows that

$$C_j(j+7,\hat{2}) = j^2(j+1)/2.$$

The sequence $C_j(j+7,\hat{2})$ appears as A002411 in Sloane's On-Line Encyclopedia of Integer Sequences [10]. A002411 is defined by

$$a(n) = n^2(n+1)/2$$

and counts the pentagonal pyramidal numbers (for a definition see [3], pp. 193-195). Clearly, $C_j(j+7,\hat{2}) = a(j)$. ■

Theorem 9 *The ninth diagonal contains the n-dimensional partitions of 5.*

Proof. For $k = 9$, we need to distribute $n - j = 8$. The partitions of 8 that do not contain a 1 are $\{8\}$, $\{6, 2\}$, $\{5, 3\}$, $\{4, 4\}$, $\{4, 2, 2\}$, $\{3, 3, 2\}$ and $\{2, 2, 2, 2\}$ and together generate a total of

$$j + 2j(j-1) + \binom{j}{2} + 2j\binom{j-1}{2} + \binom{j}{4} = j + 5\binom{j}{2} + 6\binom{j}{3} + \binom{j}{4}$$

compositions. $C_j(j+8, \hat{2})$ appears as A008779 in Sloane's On-Line Encyclopedia of Integer Sequences [10]. A008779 is defined by

$$a(n) = 1 + 6n + 11\binom{n}{2} + 7\binom{n}{3} + \binom{n}{4}$$

and counts the n-dimensional partitions of 5 (for a definition see [1], p. 179). We need to show the equivalence of the sequences $a(n)$ and $C_j(j+8, \hat{2})$ for a suitable value of n. Replacing j by $j+1$ in the expression derived above for $C_j(j+8, \hat{2})$ and simplifying shows that $C_{j+1}((j+1)+8, \hat{2}) = a(j)$, i.e., $C_j(j+8, \hat{2}) = a(j-1)$, similar to the case $k = 7$. ■

Remark. The n-dimensional partitions of 4 and 5 are not the only ones contained in the diagonals of Table 3. Further study shows that the n-dimensional partitions of 2 and 3 also occur on the diagonals. In [1], formulas for the n-dimensional partitions of k are given for $k \leq 6$. The n-dimensional partitions of 2 are given as $a(n) = n + 1$, which is the sequence in the 3rd diagonal: $C_j(j+2, \hat{2}) = a(j-1)$. The n-dimensional partitions of 3 are given as $a(n) = 1 + 2n + n(n-1)/2$, and simple algebraic manipulation shows that this sequence appears on the 5th diagonal: $C_j(j+4, \hat{2}) = a(j-1)$. A pattern emerges: for odd k, the k^{th} diagonal contains the n-dimensional partitions of $(k+1)/2$. This conjecture was very exciting because no generating function exists for this family; if a nice connection could be established, then one could compute the n-dimensional partitions in a simple way, using Theorem 4. However, the pattern does not continue: the sequence for the n-dimensional partitions of 6, namely, $\{11, 48, 140, 326, 657, 1197, \ldots\}$, which should have appeared in the 11^{th} d iagonal, does not show up. Nor does this sequence appear in the 13^{th} diagonal, the only one that has 11 as the second element.

5 The number of palindromes with no 2's

As a last exploration, let us consider the number of palindromes of n with no 2's. Table 4 lists the actual palindromes for the first few values of n.

In the following theorem, we give recursive formulas and the generating function for $P(n, \hat{2})$.

Theorem 10 *The number of palindromes of n without 2's is given by*

$$P(n, \hat{2}) = \begin{cases} C(k+1, \hat{2}), & \text{for } n = 2k, k \geq 0; \\ C(k+1, \hat{2}) + C(k-1, \hat{2}), & \text{for } n = 2k+1, k \geq 0, \end{cases}$$

with generating function $G_P(z) = \sum_{n=0}^{\infty} P(n, \hat{2}) z^n = \dfrac{1+z}{1-z^2-z^3}$.

n	1	2	3	4	5
Palindromes of n with no 2's	1	$1+1$	$1+1+1$ 3	$1+1+1+1$ 4	$1+1+1+1+1$ $1+3+1$ 5

Table 4: Palindromes of n with no 2's

Proof. In general, for odd n, begin with any odd number $1 \leq m \leq n$ as a middle entry and fill in the left side of the palindrome of n with any composition of $(n-m)/2 = j$ that has no 2's and complete the right side of the palindrome of n with the composition of j in opposite order. The total number of such palindromes is given by $P(2k+1,\hat{2}) = \sum_{j=0}^{k} C(j,\hat{2}) = C(k+1,\hat{2}) + C(k-1,\hat{2})$. For even n, we must omit the palindromes that are formed with a 2 in the middle, but do allow an even split, i.e., no middle term. Thus, $P(2k,\hat{2}) = C(k,\hat{2}) + \sum_{j=0}^{k-2} C(j,\hat{2}) = C(k+1,\hat{2})$, where the last equality follows from Eq. (2). Note that we define $P(0,\hat{2}) = 1$ similar to the definition for $C(0,\hat{2})$.

To derive the generating function, we separate $G_P(z)$ into odd and even terms, substitute the relevant formulas, factor out appropriate powers of z and express the resulting series in terms of the generating function $G_C(z^2)$:

$$\begin{aligned} G_P(z) &= \sum_{k=0}^{\infty} P(2k+1,\hat{2}) z^{2k+1} + \sum_{k=0}^{\infty} P(2k,\hat{2}) z^{2k} \\ &= \frac{1}{z}\sum_{k=0}^{\infty} C(k+1,\hat{2})(z^2)^{k+1} + z^3 \sum_{k=0}^{\infty} C(k-1,\hat{2})(z^2)^{k-1} + \\ &\quad \frac{1}{z^2}\sum_{k=0}^{\infty} C(k+1,\hat{2})(z^2)^{k+1} \\ &= G_C(z^2)\left(\frac{z+z^5+1}{z^2}\right) - \frac{1}{z} - \frac{1}{z^2}. \end{aligned}$$

Substituting the formula for $G_C(z^2)$ and simplifying gives the desired result. ∎

Table 5 gives the number of palindromes of n without 2's for $0 \leq n \leq 16$.

n	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
$P(n,\hat{2})$	1	1	1	2	2	3	4	5	7	9	12	16	21	28	37	49	65

Table 5: The number of palindromes of n without 2's

The sequence $P(2k+1,\hat{2})$ appears as A005314 in [10] as one of the sequences used to define Toeplitz matrices whose inverses contain large entries (for a definition see [8], p. 130). A005314's definition, $a(n) = 2a(n-1) - a(n-2) + a(n-3)$ is identical to

Equation 2, which counts the number of compositions. There is an easy combinatorial explanation for this fact, namely an alternative method to create palindromes. Rather than using compositions, we proceed in a manner similar to the way we created compositions recursively: Append "1+" and "+1" to the left and right end of a palindrome of (odd) n, respectively, or increase the two end summands by 1. If the palindrome consists of a single summand, increase the summand by 2 instead. Delete the palindromes that would result in a forbidden 2, and create those that have end summands 3 by adding a 3 to both ends of a palindrome of $n-6$. Thus, the total number of palindromes for odd n is given by is given by $P(2k+1,\hat{2}) = 2P(2(k-1)+1,\hat{2}) - P(2(k-2)+1,\hat{2}) + P(2(k-3)+1,\hat{2})$. Comparison of the initial terms $(a(0)=0,\ a(1)=1,\ a(2)=2)$ shows that $P(2k+1,\hat{2}) = a(k+1)$.

The complete sequence $P(n,\hat{2})$ appears in [10] as shifted sequence A000931, the Padovan sequence, with $a(n) = P(n-5,\hat{2})$, and as A078027, with $a(n) = P(n-7,\hat{2})$. Using the generating function derived in Theorem 10 and standard methods to compute the generating function of a shifted sequence (see for example [11], Rule 1, p. 34), it can be established that the sequences are identical.

6 Extensions and open problems

We have not counted the number of occurrences of the integer i in all palindromes of n, nor the number of palindromes of n with j parts. Previous experience [6] predicts that the formulas tend to be more complicated for palindromes, as it is necessary to distinguish between odd and even n, as seen also in Theorem 10 for the total number of palindromes of n.

Another problem is to ask similar questions for partitions of n without 2's. In the proofs of Theorems 5 through 9 we used partitions in order to count the compositions without 2's. Table 6 gives the number of partitions of n with no 2's, computed using *Mathematica*. No easy recursion exists to create the partitions of $n+1$ from those of n. Again the corresponding sequence is not yet listed in [10].

n	1	2	3	4	5	6	7	8	9	10	11	12	13	14
$\pi(n)$	1	1	2	3	4	6	8	11	15	20	26	35	45	58

n	15	16	17	18	19	20	21	22	23	24
$\pi(n)$	75	96	121	154	193	242	302	375	463	573

Table 6: The number of partitions of n without 2's

Abstract

We prove two new formulas for the central trinomial coefficients and the Motzkin numbers.

1 Introduction

Let c_n denote the nth *central trinomial coefficient*, defined as the coefficient of x^n in the expansion of $(1+x+x^2)^n$, or more combinatorially as the number of planar paths starting at $(0,0)$ and ending at $(n,0)$, whose allowed steps are $(1,0),(1,1),(1,-1)$. Let m_n denote the nth *Motzkin number*, defined as the number of such planar paths which do not descend below the x-axis. The first few c_n's are $1,3,7,19,51,...$, and the first few m_n's are $1,2,4,9,21,....$ We prove

Theorem 1

$$m_n = \sum_{k=\lceil (n+2)/3 \rceil}^{\lfloor (n+2)/2 \rfloor} \frac{(3k-2)!}{(2k-1)!(n+2-2k)!(3k-n-2)!} \tag{1}$$

$$c_n = (-1)^{n+1} + 2n \sum_{k=\lceil n/3 \rceil}^{\lfloor n/2 \rfloor} \frac{(3k-1)!}{(2k)!(n-2k)!(3k-n)!} \tag{2}$$

It is interesting to compare these formulas with some of the other known formulas [6] for m_n and c_n:

$$m_n = \sum_{k=0}^{\lfloor n/2 \rfloor} \frac{n!}{k!(k+1)!(n-2k)!}$$

$$m_n = \sum_{k=0}^{n} \frac{(-1)^{n+k}\, n!\,(2k+2)!}{k!\,((k+1)!)^2\,(k+2)(n-k)!}$$

$$c_n = \sum_{k=0}^{\lfloor n/2 \rfloor} \frac{n!}{(k!)^2 (n-2k)!}$$

$$c_n = \frac{1}{2^n} \sum_{k=0}^{\lfloor n/2 \rfloor} \frac{3^k (2n-2k)!}{k!(n-k)!(n-2k)!}$$

Formulas such as (1) and (2) can be proven automatically by computer, using the methods and software of Petkovšek, Wilf and Zeilberger [5]. We offer an independent, non-automatic proof that involves a certain symmetry idea which might lead to the discovery of other such identities. Two simpler auxiliary identities used in the proof are also automatically verifiable and shall not be proved.

2 Proof of the main result

Proof of (1). Our proof uses a variant of the generating function [6] for the numbers m_n, namely

$$f(x) = \frac{1 - x + \sqrt{1 + 2x - 3x^2}}{2} = 1 - x^2 + \sum_{n=3}^{\infty} (-1)^{n+1} m_{n-2} x^n$$

Then f satisfies $f(0) = 1, f(1) = 0$ and is decreasing on $[0, 1]$. Another property of f that will be essential in the proof is that it satisfies the functional equation

$$f(x)^2 - f(x)^3 = x^2 - x^3, \qquad 0 \le x \le 1, \tag{3}$$

as can easily be verified. A simple corollary of this is that $f(f(x)) = x$ for $x \in [0, 1]$.

Next, define

$$g(x) = \sum_{k=1}^{\infty} \frac{2(3k-2)!}{(2k)!(k-1)!} (x^2 - x^3)^k$$

Since on $[0, 1]$, the maximal value attained by $x^2 - x^3$ is $4/27$ (at $x = 2/3$), by Stirling's formula the series is seen to converge everywhere on $[0, 1]$, to a function $g(x)$ which is real-analytic except at $x = 2/3$. We now expand $g(x)$ in powers of $1 - x$; all rearrangement operations are permitted by absolute convergence:

$$g(x) = \sum_{k=1}^{\infty} \frac{2(3k-2)!}{(2k)!(k-1)!} x^{2k} (1-x)^k =$$

$$= \sum_{k=1}^{\infty} \frac{2(3k-2)!}{(2k)!(k-1)!} (1-x)^k \sum_{j=0}^{k} \binom{2k}{j} (-1)^j (1-x)^j =$$

$$= \sum_{n=1}^{\infty} \left(\sum_{k=\lceil n/3 \rceil}^{n} \binom{2k}{n-k} (-1)^{n+k} \frac{2(3k-2)!}{(2k)!(k-1)!} \right) (1-x)^n = 1 - x,$$

where the last equality follows from the automatically verifiable [5] identity

$$\sum_{k=\lceil n/3\rceil}^{n} \frac{(-1)^k(3k-2)!}{(k-1)!(n-k)!(3k-n)!} = 0, \qquad n > 1.$$

We have shown that $g(x) = 1 - x$ near $x = 1$. But since $g(x)$ is defined as a function of $x^2 - x^3$, by (3) it follows that $g(f(x)) = g(x)$, and therefore near $x = 0$ we have

$$g(x) = g(f(x)) = 1 - f(x) = x^2 + \sum_{n=3}^{\infty} (-1)^n m_{n-2} x^n.$$

Now to prove (1), we expand $g(x)$ into powers of x, again using easily justifiable rearrangement operations

$$g(x) = \sum_{k=1}^{\infty} \frac{2(3k-2)!}{(2k)!(k-1)!} x^{2k}(1-x)^k =$$

$$= \sum_{k=1}^{\infty} \frac{2(3k-2)!}{(2k)!(k-1)!} x^{2k} \sum_{j=0}^{k} \binom{k}{j} (-1)^j x^j =$$

$$= \sum_{n=2}^{\infty} \left((-1)^n \sum_{k=\lceil n/3\rceil}^{\lfloor n/2\rfloor} \frac{(3k-2)!}{(2k-1)!(n-2k)!(3k-n)!} \right) x^n.$$

Equating coefficients in the last two formulas gives (1). ∎

Proof of (2). We use a similar idea, this time using instead of the function $f(x)$ the function $-\log f(x)$, which generates a sequence related to c_n. Since the generating function for c_n is well known [6] to be $1/\sqrt{1-2x-3x^2}$, it is easy to verify that

$$\frac{f'(x)}{f(x)} = \sum_{n=0}^{\infty} \frac{(-1)^n c_{n+1} - 1}{2} x^n$$

and therefore

$$-\log f(x) = \sum_{n=1}^{\infty} \frac{(-1)^n c_n + 1}{2n} x^n.$$

Now define the function

$$h(x) = \sum_{k=1}^{\infty} \frac{(3k-1)!}{k!(2k)!} (x^2 - x^3)^k$$

which again converges for all $x \in [0, 1]$ to a function which is analytic except at $x = 2/3$. Expanding $h(x)$ into powers of $1 - x$ gives

$$h(x) = \sum_{k=1}^{\infty} \frac{(3k-1)!}{k!(2k)!} (1-x)^k \sum_{j=0}^{2k} \binom{2k}{j} (-1)^j (1-x)^j =$$

$$= \sum_{n=1}^{\infty} \left(\sum_{k=\lceil n/3 \rceil}^{n} \binom{2k}{n-k} (-1)^{n-k} \frac{(3k-1)!}{k!(2k)!} \right) (1-x)^n =$$

$$= \sum_{n=1}^{\infty} \frac{(1-x)^n}{n} = -\log x,$$

again making use of a verifiable identity [5], namely that

$$(-1)^n \sum_{k=\lceil n/3 \rceil}^{n} \frac{(-1)^k (3k-1)!}{k!(n-k)!(3k-n)!} = \frac{1}{n}, \qquad n \geq 1. \tag{4}$$

So $h(x) = -\log x$ near $x = 1$, and therefore because of the symmetry property (3) we have that $h(x) = -\log f(x)$ near $x = 0$. Expanding $h(x)$ in powers of x near $x = 0$ gives

$$-\log f(x) = h(x) = \sum_{k=1}^{\infty} \frac{(3k-1)!}{k!(2k)!} x^{2k} \sum_{j=0}^{k} \binom{k}{j} (-1)^j x^j =$$

$$= \sum_{n=2}^{\infty} \left((-1)^n \sum_{k=\lceil n/3 \rceil}^{\lfloor n/2 \rfloor} \frac{(3k-1)!}{(2k)!(n-2k)!(3k-n)!} \right) x^n$$

Equating coefficients with our previous expansion of $h(x)$ gives (2). ∎

Remarks.

1. One obvious question on seeing formulas (1) and (2) is, Can they be explained combinatorially? That is, do there exist bijections between sets known to be enumerated by the numbers m_n and c_n, and sets whose cardinality is seen to be the right-hand sides of (1) and (2)? Such explanations elude us currently.

2. Identity (4) is a special case of a more general identity [4, Eq. (6)] that was discovered by Thomas Liggett.

3. See [1, 2, 3, 6] for some other formulas involving the central trinomial coefficients and the Motzkin numbers, and for more information on the properties, and the many different combinatorial interpretations, of these sequences.

Abstract

A positive integer is said to be a Niven number if it is divisible by the sum of its decimal digits. We investigate the occurrence of large and small gaps between consecutive Niven numbers.

1 Introduction

A positive integer n is said to be a *Niven number* (or a Harshad number) if it is divisible by the sum of its (decimal) digits. For instance, 153 is a Niven number since 9 divides 153, while 154 is not. Niven numbers have been extensively studied; see for instance Cai [1], Cooper and Kennedy [2], Grundman [5] or Vardi [6].

Let $N(x)$ denote the number of Niven numbers $\leq x$. Recently, De Koninck and Doyon proved [3], using elementary methods, that given any $\varepsilon > 0$,

$$x^{1-\varepsilon} \ll N(x) \ll \frac{x \log\log x}{\log x}.$$

Later, using complex variables as well as probabilistic number theory, De Koninck, Doyon and Kátai [4] showed that

$$N(x) = (c + o(1))\frac{x}{\log x}, \tag{1}$$

[1]Research supported in part by a grant from NSERC.

where c is given by

$$c = \frac{14}{27} \log 10 \approx 1.1939. \tag{2}$$

In this paper, we investigate the occurrence of large gaps between consecutive Niven numbers. Secondly, denoting by $T(x)$ the number of Niven numbers $n \leq x$ such that $n+1$ is also a Niven number, we prove that

$$T(x) \ll \frac{x \log\log x}{(\log x)^2}.$$

We conclude by stating a conjecture.

2 Main results

Given a positive integer ℓ, let n_ℓ be the smallest positive integer n such that the interval $[n, n+\ell-1]$ does not contain any Niven numbers.

Theorem 1. *If ℓ is sufficiently large, then*

$$n_\ell < (100(\ell+2))^{\ell+3}.$$

Theorem 2. *As $x \to \infty$,*

$$T(x) \ll \frac{x \log\log x}{(\log x)^2}.$$

3 The search for large gaps between consecutive Niven numbers

It follows from the fact that the set of Niven numbers is of zero density that there exist arbitrarily long intervals free of Niven numbers.

Denote by $n = n(k)$ the smallest Niven number such that $n+k$ is also a Niven number while each one of $n+1, n+2, \ldots, n+k-1$ is not. The following table provides the value of $n(k)$ when k is a multiple of 10 up to 120.

k	$n(k)$
10	90
20	7560
30	28680
40	119772
50	154876
60	297864

k	$n(k)$
70	968760
80	7989168
90	2879865
100	87699842
110	497975920
120	179888904

We shall now show how one can construct arbitrary large intervals free of Niven numbers, say intervals of length ℓ, and thereby establish the proof of Theorem 1.

First, given a positive integer m, set

$$t = t(m) = \left\lfloor \frac{\log(18m)}{\log 10} \right\rfloor + 1, \tag{3}$$

where $\lfloor y \rfloor$ stands for the largest integer $\leq y$, and let m be the smallest positive integer satisfying

$$\frac{9m - 9t - 1}{9t + 2} > \ell. \tag{4}$$

Then consider integers n which can be written as the concatenation of the numbers $10^m - 1$ and d, where d is a t digit number yet to be determined, that is the $m + t$ digit number

$$n = \langle \underbrace{99\cdots9}_{m}, d \rangle = (10^m - 1) \cdot 10^t + d. \tag{5}$$

Then let $b \cdot 9m$ be the smallest multiple of $9m$ located in the interval

$$I = [\underbrace{99\cdots9}_{m}\underbrace{00\cdots0}_{t}\ ,\ \underbrace{99\cdots9}_{m+t}].$$

Note that at least two such multiples of $9m$ belong to I since the length of I is 10^t, which itself is larger than $18m$ because of (3).

We now count the number of Niven numbers belonging to the interval

$$J := [b \cdot 9m, (b+1) \cdot 9m[\subset I.$$

For any positive integer n of the form (5), it is clear that $n \in I$ and thus that $s(n)$ can take at most $9t+1$ values ranging from $9m$ to $9m+9t$. It follows that for any fixed value of $s(n)$, there is at most one multiple of $s(n)$ in the interval J, and therefore that there exist at most $9t + 1$ Niven numbers in J.

We have thus created an interval J of length $9m$ containing at most $9t+1$ Niven numbers, and therefore, by a pigeon-hole argument, containing a subinterval free of Niven numbers and of length at least $\dfrac{9m - 9t - 1}{9t + 2}$, which is larger than ℓ by condition (4), thus completing our task of constructing arbitrarily large intervals free of Niven numbers.

For example, if we require gaps of width $\ell = 100$, 200 and 300 respectively, free of Niven numbers, here is a table showing the corresponding values of m and t, as well as the length of the interval J which needs to be investigated to find the proper gap.

ℓ	m	t	length of J
100	416	4	3744
200	1028	5	9252
300	1539	5	13851

The good news about this algorithm is that by scanning relatively small intervals (of length $O(\ell \log \ell)$), we are guaranteed arbitrary large gaps. The bad news is that gaps this large are more likely to occur much sooner, as is shown, for instance, in the first table of this section in the case $\ell = 100$. Nevertheless, our algorithm provides a non trivial bound on n_ℓ, which is precisely the object of Theorem 1 which now becomes easy to proves. Indeed, if ℓ is large enough, we have in view of (4)

$$\frac{9m - 9t}{9t} < \ell + 1,$$

so that

$$m < \frac{m}{t} < \ell + 2.$$

Therefore, using (3) and (5), we have

$$\begin{aligned} n_\ell &< 10^{m+t} = 10^{\frac{m+t}{t}\cdot t} = 10^{\left(\frac{m}{t}+1\right)\cdot t} < 10^{(\ell+3)\cdot t} < 10^{(\ell+3)(\frac{\log m}{\log 10}+2)} < 10^{(\ell+3)(\frac{\log(\ell+2)}{\log 10}+2)} \\ &= e^{\log(\ell+2)^{\ell+3}} \cdot 10^{2(\ell+3)} = (\ell+2)^{\ell+3} \cdot 10^{2(\ell+3)} = (100(\ell+2))^{\ell+3}, \end{aligned}$$

which proves Theorem 1.

4 Small gaps between consecutive Niven numbers

It follows from (1) that the sum of the reciprocals of the Niven numbers diverges, and in fact that

$$\sum_{\substack{n \le x \\ n \text{ Niven number}}} \frac{1}{n} = (c + o(1)) \log\log x,$$

where c is given by (2).

We shall call *twin Niven numbers* those pairs $(n, n+1)$, such as (20,21) and (152,153), both members of which are Niven numbers. We can show that the sum of the reciprocals of twin Niven numbers converges. In fact, we can establish that if T stands for the set of twin Niven numbers $(n, n+1)$ and

$$T(x) := \#\{n \le x : (n, n+1) \in T\},$$

then

$$T(x) = O\left(\frac{x \log\log x}{(\log x)^2}\right),$$

which is precisely the statement of Theorem 2 and which implies that

$$\sum_{\substack{n \\ (n,n+1)\in T}} \frac{1}{n} < +\infty. \tag{6}$$

Indeed, using Theorem 2, one can write that

$$\sum_{\substack{n \le x \\ (n,n+1)\in T}} \frac{1}{n} = \sum_{\substack{n \\ (n,n+1)\in T}} \frac{1}{n} - \sum_{\substack{n > x \\ (n,n+1)\in T}} \frac{1}{n} = c_2 + O\left(\frac{\log\log x}{\log x}\right),$$

where

$$c_2 = 1+\frac{1}{2}+\frac{1}{3}+\cdots+\frac{1}{9}+\frac{1}{20}+\frac{1}{80}+\frac{1}{110}+\frac{1}{111}+\frac{1}{132}+\frac{1}{152}+\frac{1}{200}+\frac{1}{209}+\frac{1}{224}+\frac{1}{399}+\cdots \approx 3.07,$$

which in particular implies (6).

Before we prove Theorem 2, note that it is easy to show that T is an infinite set. This can be established by observing that 2 divides $2\cdot 10^k$ and 3 divides $2\cdot 10^k+1$ for each positive integer k.

On the other hand, using a computer, one can obtain the following table:

x	$T(x)$
10	9
100	11
1000	32

x	$T(x)$
10^4	145
10^5	904
10^6	6 191

x	$T(x)$
10^7	44 742
10^8	332 037
10^9	2 551 917

We now move to prove (6).

Let $(n, n+1) \in T$ and assume that n is a K-digit number, with $K \geq 2$. Write n as

$$n = a \cdot 10^{R+B} + b \cdot 10^R + 10^R - 1, \tag{7}$$

where a is a $K-B-R$ digit number and b is a B digit number not ending with a 9. Here B and R are non negative integers; later, we shall set B as a function of K. Now, observe that $s(n) = s(a) + s(b) + 9R$ and that $s(n+1) = s(a) + s(b) + 1$. Since $(n, n+1) \in T$, we have

$$s(n) | a \cdot 10^{R+B} + b \cdot 10^R + 10^R - 1 \quad \text{and} \quad s(n+1) | a \cdot 10^{R+B} + b \cdot 10^R + 10^R.$$

We therefore have

$$\begin{cases} b \cdot 10^R \equiv -a \cdot 10^{R+B} - 10^R + 1 \pmod{s(n)}, \\ b \cdot 10^R \equiv -a \cdot 10^{R+B} - 10^R \pmod{s(n+1)}. \end{cases}$$

Since $s(n)$ and $s(n+1)$ are relatively prime, we can use the Chinese Remainder Theorem to state that there exists one (and only one) non negative integer $m < s(n)s(n+1)$, where $m = m(a, R, B, s(n), s(n+1))$, such that

$$b \cdot 10^R \equiv m \pmod{s(n)s(n+1)}. \tag{8}$$

Observing that $(n, 10^R) = 1$ and $s(n) | n$, we have that $(s(n), 10^R) = 1$. Hence it follows from (8) that there exists one (and only one) non negative integer $m' < \dfrac{s(n)s(n+1)}{(s(n+1), 10^R)}$, where $m' = m'(a, R, B, s(n), s(n+1))$, satisfying the congruence

$$b \equiv m' \pmod{\frac{s(n)s(n+1)}{(s(n+1), 10^R)}}. \tag{9}$$

Assume for now that the integers K, R, a, B and $s(b)$ are all fixed. Since $s(n) = s(a) + s(b) + 9R$ and $s(n+1) = s(a) + s(b) + 1$, the number of b's satisfying (9) is less than

$$\frac{10^B \ (s(n+1), 10^R)}{s(n)s(n+1)} + 1.$$

Now, as the value of $s(b)$ varies from 0 to $9B-1$, the number $\Gamma = \Gamma(K, R, a, B)$ of suitable b's (that is, those satisfying (9), for K, R, a and B fixed, satisfies

$$\Gamma \leq \sum_{0 \leq s(b) \leq 9B-1} \left(\frac{10^B (s(b) + s(a) + 1, 10^R)}{(s(a) + 9R)(s(a) + 1)} + 1 \right).$$

We then have, letting $k = s(b)$,

$$\Gamma \leq \sum_{d | 10^R} \sum_{\substack{0 \leq k \leq 9B-1 \\ (k+s(a)+1, 10^R) = d}} \left(\frac{10^B \cdot d}{(s(a) + 9R)(s(a) + 1)} + 1 \right).$$

It follows that

$$\begin{aligned} \Gamma &\leq \sum_{d | 10^R} \left(\frac{9B}{d} + 1 \right) \left(\frac{10^B \cdot d}{(s(a) + 9R)(s(a) + 1)} + 1 \right) \\ &\leq \frac{(R+1)^2 \cdot 9B \cdot 10^B}{(s(a) + 9R)(s(a) + 1)} + \frac{5}{2} \frac{10^R \cdot 10^B}{(s(a) + 9R)(s(a) + 1)} + (9B+1)(R+1)^2. \end{aligned}$$

Set $B := \lfloor \log K \rfloor$. If $R > 2 \log K$, the number of n's satisfying (7) is $O(10^K / K^2)$. Therefore we may also assume that $R \leq 2 \log K$. If $s(a) \leq K/2$, one can show that the number of n's satisfying (7) is $O(10^{K\eta})$ for some positive $\eta < 1$. Hence we can make the assumption that $s(a) > K/2$. We then get that, if $B \geq 1$,

$$\Gamma \leq \frac{5 \cdot 10^B ((R+1)^2 \cdot 9B + 2 \cdot 10^R)}{K^2}.$$

From these observations, it follows that

$$\begin{aligned} T(10^K) &\leq \sum_{R \leq 2 \log K} \frac{10^K}{10^{R+B}} \frac{5 \cdot 10^B}{K^2} ((R+1)^2 \cdot 9B + 2 \cdot 10^R) \\ &= 5 \frac{10^K}{K^2} \sum_{R \leq 2 \log K} \left(9B \frac{(R+1)^2}{10^R} + 2 \right) \\ &\ll \frac{10^K \log K}{K^2}. \end{aligned}$$

Thus, given an arbitrary large x, if we choose $K = \left\lfloor \dfrac{\log x}{\log 10} \right\rfloor$, Theorem 2 follows immediately.

5 Final remarks

Most likely, one can remove the $\log\log x$ on the right hand side of (6), but we could not prove this.

On the other hand, it has been shown by Grundman [5] that, given an integer ℓ, $2 \le \ell \le 20$, one could find an infinite number of Niven numbers n such that $n+1, n+2, \ldots, n+\ell-1$ are also Niven numbers (and that there does not exist 21 consecutive numbers which are all Niven numbers). For each integer $\ell \in [2, 20]$, if we denote by $T_\ell(x)$ the number of Niven numbers $n \le x$ such that $n+1, n+2, \ldots, n+\ell-1$ are also Niven numbers, we conjecture that

$$T_\ell(x) \ll \frac{x}{\log^\ell x}.$$

6 Acknowledgements

The authors would like to thank the referee for several helpful comments which greatly improved the quality of this paper.

Abstract

Davenport and Erdős showed that the distribution of values of sums of the form

$$S_h(x) = \sum_{m=x+1}^{x+h} \left(\frac{m}{p}\right),$$

where p is a prime and $\left(\frac{m}{p}\right)$ is the Legendre symbol, is normal as $h, p \to \infty$ such that $\frac{\log h}{\log p} \to 0$. We prove a similar result for sums of the form

$$S_h(x_1, \ldots, x_n) = \sum_{z_1=x_1+1}^{x_1+h} \cdots \sum_{z_n=x_n+1}^{x_n+h} \left(\frac{z_1 + \cdots + z_n}{p}\right).$$

1. Introduction

Given a prime number p, an integer x and a positive integer h, we consider the sum

$$S_h(x) = \sum_{m=x+1}^{x+h} \left(\frac{m}{p}\right),$$

where here and in what follows $\left(\frac{m}{p}\right)$ denotes the Legendre symbol. The expected value of such a sum is $\sqrt{h}$. If p is much larger than h, it is a very difficult problem to show that there is any cancellation in an individual sum $S_h(x)$ as above. The classical inequality of Pólya-Vinogradov (see [8], [10]) shows that $S_h(x) = O(\sqrt{p}\log p)$, and assuming the Generalized Riemann Hypothesis, Montgomery and Vaughan [7] proved that $S_h(x) = O(\sqrt{p}\log\log p)$. The results of Burgess [2] provide cancellation in $S_h(x)$ for smaller values of h, as small as $p^{1/4}$. One does expect to have cancellation in $S_h(x)$ for $h > p^{\epsilon}$, for fixed $\epsilon > 0$ and p large. This would imply the well-known hypothesis of Vinogradov that the smallest positive quadratic nonresidue mod p is $< p^{\epsilon}$, for any fixed $\epsilon > 0$ and p large enough in terms of ϵ. We mention that Ankeny [1] showed that assuming the Generalized Riemann Hypothesis, the smallest positive quadratic nonresidue mod p is $O(\log^2 p)$. It is much easier to obtain cancellation, even square root cancellation, if one averages $S_h(x)$ over x. In fact, Davenport and Erdős [5] entirely solved the problem of the distribution of values of $S_h(x)$, $0 \le x < p$, as $h, p \to \infty$ such that $\frac{\log h}{\log p} \to 0$. Under these growth conditions they showed that the distribution becomes normal. Precisely, they proved that

$$\frac{1}{p} M_p(\lambda) \to \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\lambda} e^{-\frac{1}{2}t^2} dt, \quad \text{as } p \to \infty,$$

where $M_p(\lambda)$ is the number of integers x, $0 \le x < p$, satisfying $S_h(x) \le \lambda h^{\frac{1}{2}}$.

For a fixed $n \ge 2$, we consider multidimensional sums of the form

$$S_h(x_1, \dots, x_n) = \sum_{z_1=x_1+1}^{x_1+h} \cdots \sum_{z_n=x_n+1}^{x_n+h} \left(\frac{z_1 + \cdots + z_n}{p}\right), \tag{1.1}$$

where p is a prime number, $x_1, \dots, x_n$ are integer numbers, and h is a positive integer. Upper bounds for individual sums of this type have been provided by Chung [3]. In this paper we investigate the distribution of values of these sums, and obtain a result similar to that of Davenport and Erdős. Let

$$c_n := \int_0^n f(t)^2 dt, \tag{1.2}$$

where $f(t)$ is the volume of the region in $\mathbb{R}^{n-1}$ defined by

$$\{(a_1, \dots, a_{n-1}) \in \mathbb{R}^{n-1} : 0 < a_i \le 1,\ i = 1, \dots, n-1;\ t - 1 \le a_1 + \cdots + a_{n-1} < t\}.$$

We will see that this constant c_n naturally appears as a normalizing factor in our distribution result below. Let $M_{n,p}(\lambda)$ be the number of lattice points $(x_1, \dots, x_n)$ with $0 \le x_1, \dots, x_n < p$, such that

$$S_h(x_1, \dots, x_n) \le \lambda c_n^{\frac{1}{2}} h^{n-\frac{1}{2}}.$$

Then we show that as $h, p \to \infty$ such that $\frac{\log h}{\log p} \to 0$, one has

$$\frac{1}{p^n} M_{n,p}(\lambda) \to \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\lambda} e^{-\frac{t^2}{2}} dt.$$

2. Estimating the moments

We now proceed to estimate higher moments of our sums $S_h(x_1,\dots,x_n)$.

Lemma 1. *Let p be a prime number and let h and r be positive integers. Then*

$$\sum_{x_1,\dots,x_n (\mathrm{mod}\ p)} S_h^{2r}(x_1,\dots,x_n) = 1\cdot 3\cdots(2r-3)(2r-1) \cdot \left(c_n h^{2n-1} + O_{n,r}(h^{2n-2})\right)^r \left(p^n + O_r(p^{n-1})\right) + O_r\left(h^{2nr} p^{n-\frac{1}{2}}\right), \quad (2.1)$$

and

$$\sum_{x_1,\dots,x_n (\mathrm{mod}\ p)} S_h^{2r-1}(x_1,\dots,x_n) = O_r\left(h^{n(2r-1)} p^{n-\frac{1}{2}}\right). \quad (2.2)$$

Proof. Consider first the case when the exponent is $2r$. We have

$$S_h(x_1,\dots,x_n) = \sum_{a_1=1}^{h} \cdots \sum_{a_n=1}^{h} \left(\frac{x_1+\cdots+x_n+a_1+\cdots+a_n}{p}\right).$$

Therefore

$$S_h^{2r}(x_1,\dots,x_n) = \sum_{a_{1,1}=1}^{h} \cdots \sum_{a_{n,1}=1}^{h} \cdots \sum_{a_{1,2r}=1}^{h} \cdots \sum_{a_{n,2r}=1}^{h} \left(\frac{(x_1+\cdots+x_n+a_{1,1}+\cdots+a_{n,1})\cdots(x_1+\cdots+x_n+a_{1,2r}+\cdots+a_{n,2r})}{p}\right)$$

and so

$$\sum_{x_1,\dots,x_n (\mathrm{mod}\ p)} S_h^{2r}(x_1,\dots,,x_n) = \sum_{\substack{a_{i,j}=1 \\ 1\le i\le n \\ 1\le j\le 2r}}^{h} \sum_{x_1,\dots,x_n (\mathrm{mod}\ p)} \left(\frac{(x_1+\cdots+x_n+a_{1,1}+\cdots+a_{n,1})\cdots(x_1+\cdots+x_n+a_{1,2r}+\cdots+a_{n,2r})}{p}\right).$$

Divide the sets of n-tuples $\{(a_{1,i},\dots,a_{n,i}) : i = 1,\dots,2r\}$ into two types. If there exists an i such that the number of $j \in \{1,\dots,2r\}$ for which $a_{1,i}+\cdots+a_{n,i} = a_{1,j}+\cdots+a_{n,j}$ is odd, we say that it is of type 1. The others will be of type 2. First consider the sum of terms of type 1. Since for each fixed $x_2,\dots,x_n$, the product $(x_1+\cdots+x_n+a_{1,1}+\cdots+a_{n,1})\cdots(x_1+\cdots+x_n+a_{1,2r}+\cdots+a_{n,2r})$, as a polynomial in x_1, is not congruent mod p to the square of another polynomial, by Weil's bounds [11] we have

$$\sum_{x_2,\dots,x_n (\mathrm{mod}\ p)} \sum_{x_1 (\mathrm{mod}\ p)} \left(\frac{(x_1+\cdots+x_n+a_{1,1}+\cdots+a_{n,1})\cdots(x_1+\cdots+x_n+a_{1,2r}+\cdots+a_{n,2r})}{p}\right) = \sum_{x_2,\cdots,x_n (\mathrm{mod}\ p)} O_r(p^{1/2}) = O_r(p^{n-\frac{1}{2}}).$$

So the sum of terms of type 1 is $O_r\left(h^{2nr} p^{n-\frac{1}{2}}\right)$. Now consider the sum of terms of type 2. Since the polynomial $(x_1+\cdots+x_n+a_{1,1}+\cdots+a_{n,1})\cdots(x_1+\cdots+x_n+a_{1,2r}+\cdots+a_{n,2r})$ is a perfect square in this case, the Legendre symbol is 1, except for those values of $x_1,\dots,x_n$

for which this product vanishes mod p. Since the product has at most r distinct factors, for any values of $x_2, \dots, x_n$ there are at most r values of x_1 for which the product vanishes mod p. Thus the sum over $x_1, \dots, x_n$ is at most p^n, and at least $(p-r)p^{n-1}$. Hence the contribution of terms of type 2 is

$$F(h,n,r)\left(p^n + O_r(p^{n-1})\right),$$

where $F(h,n,r)$ is the number of sets $\{(a_{1,i}, \dots, a_{n,i}) : i = 1, \dots, 2r\}$ yielding multinomials of type 2, i.e., sets for which each value of $a_{1,i}+\cdots+a_{n,i}$ occurs an even number of times, as i runs over the set $\{1, 2, \dots, 2r\}$. For any integer m with $n \le m \le nh$, let $N_m(h,n)$ be the number of n-tuples $(a_{1,i}, \dots, a_{n,i})$ for which $1 \le a_{1,i}, \dots, a_{n,i} \le h$ and $a_{1,i} + \cdots + a_{n,i} = m$. Then the number of pairs of n-tuples $(a_{1,i}, \dots, a_{n,i})$, $(a_{1,j}, \dots, a_{n,j})$, with $a_{1,i}+\cdots+a_{n,i} = a_{1,j}+\cdots+a_{n,j}$, is $\sum_m (N_m(h,n))^2$. In what follows we write simply N_m instead of $N_m(h,n)$. The number of ways to choose r such pairs of n-tuples (not necessarily distinct) is $\left(\sum_m N_m^2\right)^r$, and the number of ways to arrange these pairs in $2r$ places is $(2r-1)(2r-3)\cdots 3\cdot 1$. Hence,

$$F(h,n,r) \le 1\cdot 3\cdots(2r-3)(2r-1)\left(\sum_m N_m^2\right)^r.$$

On the other hand, the number of ways of choosing r pairs of distinct sums is at least

$$\left(\sum_m N_m^2\right)\left(\sum_m N_m^2 - \max_m\{N_m^2\}\right)\cdots\left(\sum_m N_m^2 - (r-1)\max_m\{N_m^2\}\right)$$
$$\ge \left(\sum_m N_m^2 - r\max_m\{N_m^2\}\right)^r,$$

and the number of different ways to arrange them in $2r$ places is $(2r-1)(2r-3)\cdots 3\cdot 1$. Thus

$$1\cdot 3\cdots(2r-3)(2r-1)\left(\sum_m N_m^2 - r\max_m N_m^2\right)^r \le F(h,n,r)$$
$$\le 1\cdot 3\cdots(2r-3)(2r-1)\left(\sum_m N_m^2\right)^r.$$

Next, we estimate the number $N_m(h,n) = N_m$. It is clear that for any m with $0 < m \le nh$, N_m is the number of lattice points in the region R_m in $\mathbb{R}^{n-1}$ given by

$$R_m := \begin{cases} 0 < a_i \le h, \quad \text{for } i = 1, \dots, n-1; \\ m - h \le a_1 + \cdots + a_{n-1} < m. \end{cases}$$

We send the region R_m to the unit cube in $\mathbb{R}^{n-1}$ via the map $\mathbf{x} \mapsto \frac{\mathbf{x}}{h}$. Then we have

$$\overline{R_m} := \begin{cases} 0 < a_i \le 1, \quad \text{for } i = 1, \dots, n-1; \\ \frac{m}{h} - 1 \le a_1 + \cdots + a_{n-1} < \frac{m}{h}. \end{cases}$$

By the Lipschitz principle [4] we know that

$$N_m = vol(R_m) + O_n(h^{n-2}) = h^{n-1} vol(\overline{R}_m) + O_n(h^{n-2}).$$

With f defined as in the Introduction, we may write $vol(\overline{R}_m) = f(\frac{m}{h})$. Then

$$\begin{aligned}\sum_{0<m\leq nh} N_m^2 &= \sum_{0<m\leq nh} h^{2n-2}\left(f\left(\frac{m}{h}\right)\right)^2 + \sum_{0<m\leq nh} O_n(h^{2n-3})\\ &= h^{2n-1}\sum_{0<m\leq nh}\left(f\left(\frac{m}{h}\right)\right)^2\frac{1}{h} + O_n(h^{2n-2})\\ &= h^{2n-1}\int_0^n (f(t))^2\,dt + O_n(h^{2n-2})\\ &= h^{2n-1}c_n + O_n(h^{2n-2}), \quad \text{as } h\to\infty.\end{aligned}$$

Hence

$$F(h,n,r) = 1\cdot 3\cdots(2r-3)(2r-1)\left(c_n h^{2n-1} + O_{n,r}(h^{2n-2})\right)^r,$$

and (2.1) follows. It is clear that (2.2) holds, since there are no sets of type 2 in this case. This completes the proof of the lemma.

□

3. Main results

By using the estimates for the higher moments of $S_h(x_1,\dots,x_n)$ given in Lemma 1, we show that under appropriate growth conditions on h, p, the distribution of our sums $S_h(x_1,\dots,x_n)$ is normal.

Theorem 1. *Let h be any function of p such that*

$$h\to\infty, \quad \frac{\log h}{\log p}\to 0 \quad \text{as } p\to\infty. \tag{3.1}$$

Let $M_{n,p}(\lambda)$ denote the number of lattice points $(x_1,\dots,x_n)$, $0\leq x_1,\dots,x_n<p$, such that

$$S_h(x_1,\dots,x_n)\leq \lambda c_n^{\frac{1}{2}} h^{n-\frac{1}{2}},$$

with $S_h(x_1,\dots,x_n)$ defined by (1.1) and c_n defined by (1.2). Then

$$\frac{1}{p^n}M_{n,p}(\lambda)\to\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\lambda} e^{-\frac{t^2}{2}}dt, \quad \text{as } p\to\infty.$$

Proof. We consider the sum

$$\frac{1}{p^n}\sum_{x_1,\dots,x_n (\mathrm{mod}\ p)}\left(\frac{1}{c_n^{1/2}h^{n-1/2}}S_h(x_1,\dots,x_n)\right)^r. \tag{3.2}$$

It follows from the above lemma that for each fixed r and n, if r is even, then the quantity from (3.2) is

$$1\cdot 3\cdots(r-3)(r-1)\left(1+O_{n,r}\left(\frac{1}{h}\right)\right)^r\left(1+O_r\left(\frac{1}{p}\right)\right)+O_{n,r}(h^{\frac{r}{2}}p^{-\frac{1}{2}}),$$

while if r is odd, the quantity from (3.2) is $O_{n,r}(h^{\frac{r}{2}}p^{-\frac{1}{2}})$. Using (3.1), we have that for each positive integer r,

$$\frac{1}{p^n}\sum_{x_1,\dots,x_n (\mathrm{mod}\ p)}\left(\frac{1}{c_n^{1/2}h^{n-1/2}}S_h(x_1,\dots,x_n)\right)^r\to\mu_r, \quad \text{as } p\to\infty, \tag{3.3}$$

where $\mu_r = \begin{cases} 1 \cdot 3 \cdots (r-1), & \text{if } r \text{ is even;} \\ 0, & \text{if } r \text{ is odd.} \end{cases}$

Let $N_{n,p}(s)$ be the number of n-tuples $(x_1, \ldots, x_n)$ with $0 \le x_i < p$, $i = 1, \ldots, n$ such that $S_h(x_1, \ldots, x_n) \le s$. Then $N_{n,p}(s)$ is a non-decreasing function of s with discontinuities at certain integral values of s. We also note that $N_{n,p}(s) = 0$ if $s < -h^n$, $N_{n,p}(s) = p^n$ if $s \ge h^n$, and $M_{n,p}(\lambda) = N_{n,p}(\lambda c_n^{\frac{1}{2}} h^{n-\frac{1}{2}})$. We write (3.3) in the form

$$\frac{1}{p^n} \sum_{s=-h^n}^{h^n} \left(\frac{s}{c_n^{\frac{1}{2}} h^{n-\frac{1}{2}}} \right)^r (N_{n,p}(s) - N_{n,p}(s-1)) \to \mu_r, \quad \text{as } p \to \infty. \tag{3.4}$$

This is similar to relation (26) of Davenport-Erdős [5]. Following their argument, if we set

$$\Phi_{n,p}(t) = \frac{1}{p^n} N_{n,p}(t c_n^{\frac{1}{2}} h^{n-\frac{1}{2}}) = \frac{1}{p^n} M_{n,p}(t),$$

and

$$\Phi(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-\frac{1}{2}u^2} du,$$

we obtain

$$\int_{-\infty}^{\infty} t^r d\Phi_{n,p}(t) \to \int_{-\infty}^{\infty} t^r d\Phi(t), \quad \text{as } p \to \infty, \tag{3.5}$$

for any fixed positive integer r, which is the analogue of relation (28) from [5]. It now remains to show that, for each real number λ,

$$\Phi_{n,p}(\lambda) \to \Phi(\lambda), \quad \text{as } p \to \infty. \tag{3.6}$$

The assertion of (3.6) follows from the well-known fact (see [6]) in the theory of probability that if F_k and F are probability distributions with finite moments $m_{k,r}$, m_r of all orders, respectively, and if F is the unique distribution with the moments m_r such that $m_{k,r} \to m_r$ for all r as $k \to \infty$, then $F_k \to F$ as $k \to \infty$. We give the outline of the proof following the argument of Davenport-Erdős [5]. Suppose that (3.6) fails for some λ. Then we can find a subsequence $\{\Phi_{n,p'}\}$ and a $\delta > 0$ such that

$$|\Phi_{n,p'}(\lambda) - \Phi(\lambda)| \ge \delta, \quad \text{for all } p'. \tag{3.7}$$

By the two theorems of Helly (see the introduction to [9]) there exists a subsequence $\{\Phi_{n,p''}\}$ of $\{\Phi_{n,p'}\}$ which converges to a distribution Ψ at every point of continuity, and

$$\int_{-\infty}^{\infty} t^r d\Psi(t) = \lim_{p'' \to \infty} \int_{-\infty}^{\infty} t^r d\Phi_{n,p''} = \int_{-\infty}^{\infty} t^r d\Phi(t).$$

Since Φ is the only distribution with these special moments $\mu_1, \mu_2, \ldots$, we have $\Psi(t) = \Phi(t)$ for all t. This contradicts (3.7). Hence one concludes that, as $p \to \infty$,

$$\frac{1}{p^n} M_{n,p}(\lambda) = \Phi_{n,p}(\lambda) \to \Phi(\lambda) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\lambda} e^{-\frac{1}{2}t^2} dt,$$

which completes the proof of the theorem. □

We remark that c_n can be explicitly computed for any given value of n. The following proposition provides an equivalent formulation of c_n, which allows for easier computations in higher dimensions. For any n, consider the polynomial in two variables

$$g_n(X,Y) = \sum_{l=0}^{n-1} \left(\sum_{k=0}^{l} (-1)^k \binom{n}{k} \binom{X + (l-k)Y + n - 1}{n-1} \right)^2 .$$

Note that the total degree of $g_n(X,Y)$ is at most $2n-2$.

Proposition 1. *For any n,*

$$c_n = \sum_{k=0}^{2n-2} \frac{a_{n,k}}{k+1} ,$$

where $a_{n,k}$ is the coefficient of $X^k Y^{2n-2-k}$ in $g_n(X,Y)$.

Proof. We know that for fixed n and $h \to \infty$,

$$\sum_m N_m^2 = h^{2n-1} c_n + O_n(h^{2n-2}),$$

where $N_m = N_m(h,n)$ is the number of n-tuples $(a_1, \ldots, a_n)$ such that $a_1 + \cdots + a_n = m$, with $1 \le a_i \le h$. Replacing m by $m' = m - n$ and each a_i by $b_i = a_i - 1$, we get $\sum_m N_m^2 = \sum_{m'} (N'_{m'})^2$, where $N'_{m'}$ is the number of n-tuples $(b_1, \ldots, b_n)$ such that $b_1 + \cdots + b_n = m'$, with $0 \le b_i \le h-1$.

Now, the number of ways to obtain a sum of m' from n non-negative integers, with no restrictions, is $\binom{m'+n-1}{n-1}$. If we restrict any fixed b_i to satisfy the inequality $b_i \ge h$, then the number of ways drops to $\binom{m'-h+n-1}{n-1}$. If we restrict any two b_i, b_j to satisfy $b_i, b_j \ge h$ then we have $\binom{m'-2h+n-1}{n-1}$ ways, and so on.

Since for each k, there are $\binom{n}{k}$ ways to choose exactly k of the b_i's to be greater than h, we obtain by the inclusion-exclusion principle,

$$N'_{m'} = \sum_{0 \le k \le m'/h} (-1)^k \binom{n}{k} \binom{m' - kh + n - 1}{n-1}.$$

So we have, for $lh \le m' < (l+1)h$, $0 \le l \le n-1$,

$$N'_{m'} = \sum_{k=0}^{l} (-1)^k \binom{n}{k} \binom{m' - kh + n - 1}{n-1}.$$

Replacing m' by $s + lh$, with $0 \le s \le h-1$, we get

$$N'_{s+lh} = \sum_{k=0}^{l} (-1)^k \binom{n}{k} \binom{s + (l-k)h + n - 1}{n-1}.$$

Therefore

$$\begin{aligned} \sum_{m'} (N'_{m'})^2 &= \sum_{s=0}^{h-1} \sum_{l=0}^{n-1} \left(\sum_{k=0}^{l} (-1)^k \binom{n}{k} \binom{s + (l-k)h + n - 1}{n-1} \right)^2 \\ &= \sum_{s=0}^{h-1} g_n(s,h). \end{aligned}$$

It follows that

$$\sum_{s=0}^{h-1} g_n(s,h) = h^{2n-1}c_n + O_n(h^{2n-2}). \tag{3.8}$$

Now, the main contribution in $g_n(s,h)$ comes from the terms where the exponents of s and h add up to $2n-2$. Since for any $0 \le k \le 2n-2$,

$$\sum_{s=0}^{h-1} s^k = \frac{1}{k+1}h^{k+1} + O_n(h^k),$$

we obtain

$$\begin{aligned}\sum_{s=0}^{h-1} g_n(s,h) &= \sum_{s=0}^{h-1}\left(\sum_{k=0}^{2n-2} a_{n,k}s^k h^{2n-2-k} + \text{lower order terms}\right)\\ &= \sum_{k=0}^{2n-2}\sum_{s=0}^{h-1} a_{n,k}s^k h^{2n-2-k} + O_n(h^{2n-2})\\ &= \sum_{k=0}^{2n-2}\frac{a_{n,k}}{k+1}h^{2n-1} + O_n(h^{2n-2}).\end{aligned}$$

By combining this with (3.8), we obtain the desired result. □

For $n = 2,3,4,5,6$, one finds that $c_2 = \frac{2}{3}$, $c_3 = \frac{11}{20}$, $c_4 = \frac{151}{315}$, $c_5 = \frac{15619}{36288}$, $c_6 = \frac{655177}{1663200}$. The numerator and the denominator of c_n grow rapidly as n increases. For instance, for $n = 10$ and $n = 25$ we have

$$c_{10} = \frac{37307713155613}{121645100408832},$$

and

$$c_{25} = \frac{675361967823236555923456864701225753248337661154331976453}{34659935272607838226339154605202015777068537400524800000000}.$$

One can also work with boxes instead of cubes, and obtain similar distribution results. For example, in dimension two, we may consider the sum

$$S_{h,k}(x,y) = \sum_{u=x+1}^{x+h}\sum_{v=y+1}^{y+k}\left(\frac{u+v}{p}\right),$$

where x, y are any integers and h, k are positive integers, with $h \ge k$, say. Then, by using the same arguments as in the proof of Theorem 1, one can prove the following result.

Theorem 2. *Let h, k be functions of p such that*

$$h \ge k, \quad \frac{h}{k} \to \alpha, \quad k \to \infty, \quad \frac{\log k}{\log p} \to 0, \quad \text{as } p \to \infty.$$

Denote $\beta = \sqrt{\alpha - \frac{1}{3}}$ and $\beta' = \sqrt{1 - \frac{1}{3\alpha}}$. Let $M_p(\lambda)$ be the number of pairs (x,y) with $0 \le x,y < p$, x, y integers, such that $S_{h,k}(x,y) \le \lambda\beta k^{\frac{3}{2}}$. Let $M_p'(\lambda)$ be the number of pairs (x,y) with $0 \le x,y < p$, x, y integers, such that $S_{h,k}(x,y) \le \lambda\beta' h^{\frac{1}{2}}k$. Then, as $p \to \infty$,

$$\frac{1}{p^2}M_p(\lambda) \to \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\lambda} e^{-\frac{1}{2}x^2}dx,$$

and

$$\frac{1}{p^2}M_p{}'(\lambda) \to \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\lambda} e^{-\frac{1}{2}x^2}dx.$$

We remark that when h is much larger than k, $S_{h,k}(x,y)$ is close to k times the 1-dimensional sum $S_h(x+y)$. Also, in this case α is large, β' is close to 1, and the above statement for $M_p{}'(\lambda)$ approaches the 1-dimensional result of Davenport and Erdős. Note also that in case $\alpha = 1$, we have $\beta = \sqrt{2/3} = \sqrt{c_2}$, and the statement of Theorem 2 for $M_p(\lambda)$ coincides with that of Theorem 1 for $n = 2$.

Abstract

In 2003 Cohen and Iannucci introduced a multiplicative arithmetic function D by assigning $D(p^a) = ap^{a-1}$ when p is a prime and a is a positive integer. They defined $D^0(n) = n$ and $D^k(n) = D(D^{k-1}(n))$ and they called $\{D^k(n)\}_{k=0}^{\infty}$ the derived sequence of n. This paper answers some open questions about the function D and its iterates. We show how to construct derived sequences of arbitrary cycle size, and we give examples for cycles of lengths up to 10. Given n, we give a method for computing m such that $D(m) = n$, up to a square free unitary factor.

1. Introduction and Results

Cohen and Iannucci [1] introduced a multiplicative arithmetic function D by assigning $D(p^a) = ap^{a-1}$ when p is a prime and a is a positive integer. They defined $D^0(n) = n$ and $D^k(n) = D(D^{k-1}(n))$ and they called $\{D^k(n)\}_{k=0}^{\infty}$ the derived sequence of n. Cohen and Iannucci showed that for all $n < 1.5 \times 10^{10}$ the derived sequences are bounded. Moreover, they showed that the set of n where the derived sequence of n is bounded has a density of at least 0.996. Bounded sequences effectively end in a cycle. Although Cohen and Iannucci found only cycles of lengths 1 to 6, and 8, they conjectured the existence of cycles of any order. This paper gives a constructive proof for the existence of cycles of any order.

Given n, an integer m such that $D(m) = n$ is referred to as a value of $D^{-1}(n)$, and m is called canonical if it has no square free unitary factor. (A factor d of n is unitary if

[1]Research of K. G. Hare supported, in part by NSERC of Canada, and by the Department of Mathematics, University of California, Berkeley.
[2]Research of S. Yazdani supported, in part by NSERC of Canada, and by the Department of Mathematics, University of California, Berkeley.

$\gcd(d, n/d) = 1$ and square free if $p^2 \nmid d$ for any prime p.) We give a method for computing canonical values of $D^{-1}(n)$ and we give an example where $D^{-1}(n)$ has at least 2^{7101} different canonical values.

2. Cycles of arbitrary order

We say that the derived sequence has a cycle of order $r > 0$ if for sufficiently large k we have $D^{k+r}(n) = D^k(n)$ and r is minimal.

For example, we see that the derived sequence of $n = 4$ is

$$\{2^2,\ 2^2,\ 2^2,\ \cdots\}$$

and hence this has a cycle of order 1. Considering the derived sequence of $n = 16$ gives

$$\{2^4,\ 2^5,\ 5 \cdot 2^4,\ 2^5,\ 5 \cdot 2^4,\ \cdots\}$$

and hence this has a cycle of order 2.

First we introduce some notation: Let $\bar{p} = [p_1, p_2, \cdots, p_k]$ and $\bar{a} = [a_1, a_2, \cdots, a_k]$. Then we use the notation

$$\bar{p}^{\bar{a}} := p_1^{a_1} \cdot p_2^{a_2} \cdots p_k^{a_k}.$$

Here we show how to create a cycle of arbitrary order. First we need a lemma:

Lemma 2.1. *Let k be odd. Let $\gcd(a, k)$ and $\gcd(b, k)$ be square free. Then there exists an n such that $a + kn$ and $b + kn$ are both square free.*

Proof. We do this by showing that the set of n with the property that $a + kn$ and $b + kn$ are square free has positive density. For a subset $U \subset \mathbb{N}$, let

$$\text{Density}(U) = \lim_{n \to \infty} \frac{\#\{x \in U : x < n\}}{n}.$$

For p prime, define:

$$R_p := \{n \in \mathbb{N} : a + kn \not\equiv 0 \pmod{p^2} \text{ and } b + kn \not\equiv 0 \pmod{p^2}\}$$

and $S_p = \text{Density}(R_p)$.

If $p|k$ then S_p either equals 1, $1 - \frac{1}{p}$, or $1 - \frac{2}{p}$. (It is worth remarking here that if k is even, and we took $p = 2$ then $1 - \frac{2}{p} = 0$, and hence positive density is not necessarily shown.) If $p \nmid k$ then S_p either equals $1 - \frac{1}{p^2}$ or $1 - \frac{2}{p^2}$. Let

$$\begin{aligned} R &= \{n \in \mathbb{N} : a + kn \text{ and } b + kn \text{ are square free }\} \\ &= \bigcap_{p \text{ prime}} R_p. \end{aligned}$$

Then, we get that the density of R is

$$\begin{aligned} \prod_{p \text{ prime}} S_p &= \prod_{p|k} (S_p) \prod_{p \nmid k} (S_p) \\ &\geq \prod_{p|k} \left(1 - \frac{2}{p}\right) \prod_{p \nmid k} \left(1 - \frac{2}{p^2}\right). \end{aligned}$$

We see that the first product is positive, as there are only a finite number of primes p such that $p|k$. We see that the second infinite product is positive because $\sum \frac{2}{p^2}$ converges.

Thus we see that the density of n where $a+nk$ and $b+nk$ are both square free is positive, hence there exists at least one. □

Theorem 2.1. *There exist cycles of every order.*

Proof. This result is proved by constructing a cycle of order k for arbitrary k. Pick $k > 1$. Pick k distinct odd primes $p_1, \cdots, p_k$.

For $\bar{a} = [a_1, \cdots, a_k]$ let $\bar{a}_i = [a_1, \cdots, a_{i-1}, a_i + 1, a_{i+1}, \cdots, a_k]$. The goal is to find an $\bar{a}$ such that

$$D(\bar{p}^{\bar{a}_1}) = s_1 \cdot \bar{p}^{\bar{a}_2}$$

and in general

$$D(\bar{p}^{\bar{a}_i}) = s_i \cdot \bar{p}^{\bar{a}_{i+1}}$$

where $i+1$ is taken modulo k, and the s_i are square free coprime to $p_1 \cdot p_2 \cdots p_k$. Then for any i, $\bar{p}^{\bar{a}_i}$ gives a cycle of order k.

Note that if we find a_i such that

- a_i is square free,
- $a_i + 1$ is square free,
- $\gcd(a_i, p_i) = p_i$,
- $\gcd(a_i + 1, p_{i+1}) = p_{i+1}$,
- $\gcd(a_i, p_j) = 1$ for $j \neq i$,
- $\gcd(a_i + 1, p_j) = 1$ for $j \neq i + 1$,
- $\gcd(a_i + 1, a_1 a_2 \cdots a_{i-1}) = 1$ for $i > 1$,
- $\gcd(a_i, a_1 a_2 \cdots a_{i-1}) = 1$ for $i > 1$,
- $\gcd(a_i, (a_1 + 1)(a_2 + 1) \cdots (a_{i-1} + 1)) = 1$ for $i > 1$,

then $\bar{a} = [a_1, \cdots, a_k]$ has the desired property. It is worth noting here that the last two conditions require all of the a_i to be odd. To see that $\bar{a}$ has the desired property, note that

$$D(s_{i-1}\bar{p}^{\bar{a}_i}) = D(\bar{p}^{\bar{a}_i}) = a_1 a_2 \cdots (a_i + 1) \cdots a_n \bar{p}^{\bar{a}_i - 1} = s_i \bar{p}^{a_{i+1}},$$

where the last equality follows from the properties of $\bar{a}$.

We can solve for each a_i in order by the use of the Chinese remainder Theorem and Lemma 2.1. □

In Table 1, $\bar{a}$ is given for cycles of sizes 2 to 10 for the first 10 primes. It should be noted that this construction does not give the smallest n where the derived sequence is of order k. For example, let $s_1 = 2 \cdot 7$ and $s_2 = 2 \cdot 23$ then $s_2 \cdot 3^{70} \cdot 5^5$ and $s_1 \cdot 3^{69} \cdot 5^6$ gives rise to a cycle of order two. The smallest cycle of order two is 2^5 and $5 \cdot 2^4$, which is considerably smaller.

Cycle Size	Primes									
	3	5	7	11	13	17	19	23	29	31
2	69	5								
3	129	265	77

TABLE 1. $\bar{a}$ that give rise to an various cycle sizes.

3. Computing $D^{-1}(n)$.

By noticing that $D(s) = 1$ for all square free numbers s, we see that if we have $D(m) = n$ then $D(ms) = n$ for all square free factors s coprime to m. To eliminate these trivial alternate values to $D^{-1}(n)$, we introduce the definition:

Definition 3.1. *If $\bar{p}^{\bar{b}}$ has no square free components (i.e. $b_i \neq 1$ for all i) and $D(\bar{p}^{\bar{b}}) = n$ then we say that $\bar{p}^{\bar{b}}$ is a canonical value of $D^{-1}(n)$. We define $D_c(n)$ to be the set of all canonical values of $D^{-1}(n)$.*

To compute $D_c(n)$ we need the following lemma.

Lemma 3.1. *If $n = \bar{p}^{\bar{a}}$ and $D_c(n) \neq \emptyset$, then for every $k \in D_c(n)$ we have $k = \bar{p}^{\bar{b}}$. Furthermore $0 \leq b_i \leq a_i + 1$.*

Proof. This follows immediately by applying D to $\bar{p}^{\bar{b}}$. □

In particular an element of $D_c(n)$ cannot have prime factors that are not also factors of n.

Corollary 3.1. *Let p be a prime. Then $D_c(p^a) \neq \emptyset$ if and only if $a = p^k + k - 1$ for some k. Further $D_c(p^{p^k+k-1}) = \{p^{p^k}\}$.*

Corollary 3.2. *If s is an odd square free number, then $D_c(s) = \emptyset$.*

Given Lemma 3.1, it is an easy matter to determine $D_c(n)$. Simply compute $D(\bar{p}^{\bar{b}})$ where $0 \leq b_i \leq a_i + 1$ and $b_i \neq 1$, and check which ones work. For large exponents $\bar{b}$ this is not particularly efficient, but it suffices for $n < 10^7$.

We see from Corollary 3.1 and 3.2 that $D_c(n)$ is empty for some values n. Table 2 lists $D_c(n)$, if they are nonempty, for all $n \leq 100$. It is worth noting that, in the case of the first 100, there is a unique canonical value in $D_c(n)$. This is not true in general. The first example when $D_c(n)$ does not have a unique element is $108 = 2^2 \cdot 3^3$ for which we $D_c(108) = \{2^2 \cdot 3^3,\ 3^4\}$. The first six examples of multiple canonical values, less than 2000 are listed in Table 3.

We have the following results concerning the non-uniqueness of the canonical values in $D_c(n)$.

n	$D_c(n)$
$1 = 1$	$\{1 = 1\}$
$4 = 2^2$	$\{4 = 2^2\}$
$6 = 2 \cdot 3$	$\{9 = 3^2\}$
$10 = 2 \cdot 5$	$\{25 = 5^2\}$
$12 = 2^2 \cdot 3$	$\{8 = 2^3\}$
$14 = 2 \cdot 7$	$\{49 = 7^2\}$
$22 = 2 \cdot 11$	$\{121 = 11^2\}$
$24 = 2^3 \cdot 3$	$\{36 = 2^2 \cdot 3^2\}$
$26 = 2 \cdot 13$	$\{169 = 13^2\}$
$27 = 3^3$	$\{27 = 3^3\}$
$32 = 2^5$	$\{16 = 2^4\}$
$34 = 2 \cdot 17$	$\{289 = 17^2\}$
$38 = 2 \cdot 19$	$\{361 = 19^2\}$
$40 = 2^3 \cdot 5$	$\{100 = 2^2 \cdot 5^2\}$
$46 = 2 \cdot 23$	$\{529 = 23^2\}$
$56 = 2^3 \cdot 7$	$\{196 = 2^2 \cdot 7^2\}$
$58 = 2 \cdot 29$	$\{841 = 29^2\}$
$60 = 2^2 \cdot 3 \cdot 5$	$\{225 = 3^2 \cdot 5^2\}$
$62 = 2 \cdot 31$	$\{961 = 31^2\}$
$72 = 2^3 \cdot 3^2$	$\{72 = 2^3 \cdot 3^2\}$
$74 = 2 \cdot 37$	$\{1369 = 37^2\}$
$75 = 3 \cdot 5^2$	$\{125 = 5^3\}$
$80 = 2^4 \cdot 5$	$\{32 = 2^5\}$
$82 = 2 \cdot 41$	$\{1681 = 41^2\}$
$84 = 2^2 \cdot 3 \cdot 7$	$\{441 = 3^2 7^2\}$
$86 = 2 \cdot 43$	$\{1849 = 43^2\}$
$88 = 2^3 \cdot 11$	$\{484 = 2^2 \cdot 11^2\}$
$94 = 2 \cdot 47$	$\{2209 = 47^2\}$

TABLE 2. $D_c(n)$ for $n \leq 100$ when $D_c(n)$ is non-empty.

n	$D_c(n)$
$108 = 2^2 \cdot 3^3$	$\{81 = 3^4, 108 = 2^2 \cdot 3^3\}$
$192 = 2^6 \cdot 3$	$\{144 = 2^4 \cdot 3^2, 64 = 2^6\}$
$448 = 2^6 \cdot 7$	$\{784 = 2^4 \cdot 7^2, 128 = 2^7\}$
$1080 = 2^3 \cdot 3^3 \cdot 5$	$\{2025 = 3^4 \cdot 5^2, 2700 = 2^2 \cdot 3^3 \cdot 5^2\}$

TABLE 3. Examples of two different Canonical values, for $n \leq 2000$

Lemma 3.2. *If $m \in D_c(p+1)$, then $D_c((p+1)p^p)$ has at least two elements, namely $m \cdot p^p$ and p^{p+1}.*

Proof. One only needs to check that m is coprime to p, which follows from Lemma 3.1. □

Lemma 3.3. *If $D_c(n)$ and $D_c(m)$ have k and l elements in them, and for every $x \in D_c(n)$ and $y \in D_c(m)$ we have $\gcd(x, y) = 1$, then $D_c(nm)$ has at least kl elements.*

Proof. For $x \in D_c(n)$ and $y \in D_c(m)$, note that $D(xy) = D(x)D(y) = mn$, since x and y are coprime. □

Example 1. *Notice that:*

$$D_c(3 \cdot 2 \cdot 5^5) = \{5^6,\ 5^5 \cdot 3^2\}$$

and

$$D_c(2 \cdot 7 \cdot 13^{13}) = \{13^{14},\ 7^2 \cdot 13^{13}\}.$$

Combining these together, either by Lemma 3.3, or by direct computation we get

$$\begin{aligned} D_c(2^2 \cdot 3 \cdot 5^5 \cdot 7 \cdot 13^{13}) \ = \ & \{13^{14} \cdot 5^6,\ 7^2 \cdot 13^{13} \cdot 5^6, \\ & 13^{14} \cdot 3^2 \cdot 5^5,\ 7^2 \cdot 13^{13} \cdot 3^2 \cdot 5^5\}. \end{aligned}$$

It should be noted that Lemma 3.3 only shows that these four values are contained in $D_c(2^2 \cdot 3 \cdot 5^5 \cdot 7 \cdot 13^{13})$. Equality comes from direct computation.

In particular if p and $2p-1$ are both prime, then for $n = 2 \cdot p \cdot (2p-1)^{2p-1}$ we have $D_c(n)$ has at least 2 elements, namely $p^2 \cdot (2p-1)^{2p-1}$ and $(2p-1)^{2p}$. Primes with this property are similar to Sophie Germain primes, in which p and $2p+1$ must both be prime [2, 3]. It is not known if there are infinitely many Sophie Germain primes, and there do not appear to be any results of primes p where $2p-1$ is also prime. If anything is learned about primes of this form, then the following Theorem can be strengthened. In particular, if Dickson's Conjecture is true (see for instance page 180 of [4]), then there are an infinite number of primes p such that $2p-1$ is also prime. In this case, this Theorem can be strengthen, by replacing 2^{7101} with M an arbitrarily large number.

Theorem 3.1. *There exists an n such that $D_c(n)$ has at least 2^{7101} elements.*

Proof. A quick computation verifies that there are 7101 primes p less than a million, where $2p-1$ is also prime, and all of these terms are coprime. Let $P_i := 2p_i - 1$. By Lemma 3.2 we see that $D_c(2 \cdot p_i \cdot P_i^{P_i})$ has (at least) two elements, $P_i^{P_i+1}$ and $P_i^{P_i} \cdot p_i^2$. By Lemma 3.3 we see that if $n = \prod 2 \cdot p_i \cdot P_i^{P_i}$ then $D_c(n)$ has at least 2^{7101} elements. □

4. Conclusions

In Section 3 we considered primes p where $2p-1$ is also prime. An interesting observation is that, empirically, there appears to be the same number of these types of primes as there are of Sophie Germain primes.

In [1], Cohen and Iannucci conjectured the existence of n such that the derived sequence of n is unbounded. It would be interesting to know if this is in fact true or not.

It would also be interesting to explore the properties of the D function if it is extended in the natural way to rational numbers. For example: $D\left(\frac{16}{9}\right) = D\left(2^4 \cdot 3^{-2}\right) = 4 \cdot 2^3 \cdot (-2) \cdot 3^{-3} = -2^6 \cdot 3^{-3} = -\frac{64}{27}$ and $D(-1) = -1$.

5. Acknowledgment

We would like to thank the organizers of the West Coast Number Theory conference, where we were first introduced to this problem. We would also like to thank the referee for a number of very useful comments and suggestions.

Abstract

Using the saddle point method, we obtain from the generating function of the inversion numbers of permutations and Cauchy's integral formula asymptotic results in central and noncentral regions.

1 Introduction

Let $a_1 \cdots a_n$ be a permutation of the set $\{1, \ldots, n\}$. If $a_i > a_k$ and $i < k$, the pair (a_i, a_k) is called an *inversion*; $I_n(j)$ is the number of permutations of length n with j inversions. In a recent paper [7], several facts about these numbers are nicely reviewed, and—as new results—asymptotic formulæ for the numbers $I_{n+k}(n)$ for fixed k and $n \to \infty$ are derived. This is done using Euler's pentagonal theorem, which leads to a handy explicit formula for $I_n(j)$, valid for $j \leq n$ only.

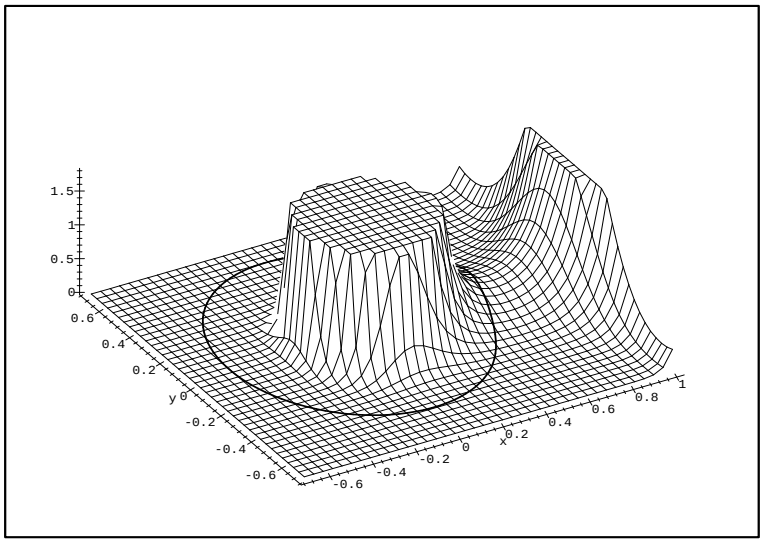

Figure 1: $|\Phi_{10}(z)/z^{11}|$ and the path of integration

Here, we show how to extend these results using the *saddle point method*. This leads, e. g., to asymptotics for $I_{\alpha n+\beta}(\gamma n+\delta)$, for integer constants α, β, γ, δ and more general ones as well. With this technique, we will also show the known result that $I_n(j)$ is asymptotically normal.

The generating function for the numbers $I_n(j)$ is given by

$$\Phi_n(z) = \sum_{j\geq 0} I_n(j) z^j = (1-z)^{-n} \prod_{i=1}^{n} (1-z^i).$$

By Cauchy's theorem,

$$I_n(j) = \frac{1}{2\pi i} \int_{\mathcal{C}} \Phi_n(z) \frac{dz}{z^{j+1}},$$

where $\mathcal{C}$ is, say, a circle around the origin passing (approximately) through the saddle point. In Figure 1, the saddle point (near $z = \frac{1}{2}$) is shown for $n = j = 10$.

As general references for the application of the saddle point method in enumeration we cite [4, 8].

Actually, we obtain here local limit theorems with some corrections (=lower order terms). For other such theorems in large deviations of combinatorial distributions, see, for instance, Hwang [5].

The paper is organized as follows: Section 2 deals with the Gaussian limit. In Section 3, we analyze the case $j = n-k$, that we generalize in Section 4 to the case $j = \alpha n - x$, $\alpha > 0$. Section 5 is devoted to the moderate large deviation, and Section 6 to the large deviation. Section 7 concludes the paper.

2 The Gaussian limit, $j = m + x\sigma, m = n(n-1)/4$

The Gaussian limit of $I_n(j)$ is easily derived from the generating function $\Phi_n(z)$ (using the Lindeberg-Lévy conditions, see for instance, Feller [3]); this is also reviewed in Margolius' paper, following Sachkov's book [9]. Another analysis is given in Bender [2]. Indeed, this generating function corresponds to a sum for $i = 1, \ldots, n$ of independent, uniform $[0..i-1]$ random variables. As an exercise, let us recover this result with the *saddle point method,* with an additional correction of order $1/n$. We have, with $J_n := I_n/n!$,

$$\begin{aligned} m := \mathbb{E}(J_n) &= n(n-1)/4, \\ \sigma^2 := \mathbb{V}(J_n) &= n(2n+5)(n-1)/72. \end{aligned}$$

We know that

$$I_n(j) = \frac{1}{2\pi i} \int_\Omega \frac{e^{S(z)}}{z^{j+1}} dz$$

where Ω is inside the analyticity domain of the integrand and encircles the origin. Since $\Phi_n(z)$ is just a polynomial, the analyticity restriction can be ignored. We split the exponent of the integrand $S = \ln(\Phi_n(z)) - (j+1)\ln z$ as follows:

$$\begin{aligned} S &:= S_1 + S_2, \\ S_1 &:= \sum_{i=1}^{n} \ln(1 - z^i), \\ S_2 &:= -n\ln(1-z) - (j+1)\ln z. \end{aligned} \tag{1}$$

Set

$$S^{(i)} := \frac{d^i S}{dz^i}.$$

To use the saddle point method, we must find the solution of

$$S^{(1)}(\tilde{z}) = 0. \tag{2}$$

Set $\tilde{z} := z^* - \varepsilon$, where, here, $z^* = 1$. (This notation always means that z^* is the approximate saddle point and $\tilde{z}$ is the exact saddle point; they differ by a quantity that has to be computed to some degree of accuracy.) This leads, to first order, to the equation

$$[(n+1)^2/4 - 3n/4 - 5/4 - j] + [-(n+1)^3/36 + 7(n+1)^2/24 - 49n/72 - 91/72 - j]\varepsilon = 0. \tag{3}$$

Set $j = m + x\sigma$ in (3). This shows that, asymptotically, ε is given by a *Puiseux series* of powers of $n^{-1/2}$, starting with $-6x/n^{3/2}$. To obtain the next terms, we compute the next terms in the expansion of (2), i.e., we first obtain

$$\begin{aligned} &[(n+1)^2/4 - 3n/4 - 5/4 - j] + [-(n+1)^3/36 + 7(n+1)^2/24 - 49n/72 - 91/72 - j]\varepsilon \\ &+ [-j - 61/48 - (n+1)^3/24 + 5(n+1)^2/16 - 31n/48]\varepsilon^2 = 0. \end{aligned} \tag{4}$$

More generally, even powers ε^{2k} lead to a $\mathcal{O}(n^{2k+1}) \cdot \varepsilon^{2k}$ term and odd powers ε^{2k+1} lead to a $\mathcal{O}(n^{2k+3}) \cdot \varepsilon^{2k+1}$ term. Now we set $j = m + x\sigma$, expand into powers of $n^{-1/2}$ and equate each

coefficient with 0. This leads successively to a full expansion of ε. Note that to obtain a given precision of ε, it is enough to compute a given finite number of terms in the generalization of (4). We obtain

$$\begin{aligned}\varepsilon = &-6x/n^{3/2} + (9x/2 - 54/25x^3)/n^{5/2} - (18x^2+36)/n^3 \\ &+ x[-30942/30625x^4 + 27/10x^2 - 201/16]/n^{7/2} + \mathcal{O}(1/n^4). \end{aligned} \tag{5}$$

We have, with $\tilde{z} := z^* - \varepsilon$,

$$J_n(j) = \frac{1}{n!2\pi i}\int_\Omega \exp\left[S(\tilde{z}) + S^{(2)}(\tilde{z})(z-\tilde{z})^2/2! + \sum_{l=3}^{\infty} S^{(l)}(\tilde{z})(z-\tilde{z})^l/l!\right]dz$$

(note carefully that the linear term vanishes). Set $z = \tilde{z} + i\tau$. This gives

$$J_n(j) = \frac{1}{n!2\pi}\exp[S(\tilde{z})]\int_{-\infty}^{\infty} \exp\left[S^{(2)}(\tilde{z})(i\tau)^2/2! + \sum_{l=3}^{\infty} S^{(l)}(\tilde{z})(i\tau)^l/l!\right]d\tau. \tag{6}$$

Let us first analyze $S(\tilde{z})$. We obtain

$$\begin{aligned} S_1(\tilde{z}) &= \sum_{i=1}^{n}\ln(i) + [-3/2\ln(n) + \ln(6) + \ln(-x)]n + 3/2x\sqrt{n} + 43/50x^2 - 3/4 \\ &\quad + [3x/8 + 6/x + 27/50x^3]/\sqrt{n} + [5679/12250x^4 - 9/50x^2 + 173/16]/n + \mathcal{O}(n^{-3/2}), \\ S_2(\tilde{z}) &= [3/2\ln(n) - \ln(6) - \ln(-x)]n - 3/2x\sqrt{n} - 34/25x^2 + 3/4 \\ &\quad - [3x/8 + 6/x + 27/50x^3]/\sqrt{n} - [5679/12250x^4 - 9/50x^2 + 173/16]/n + \mathcal{O}(n^{-3/2}), \end{aligned}$$

and so

$$S(\tilde{z}) = -x^2/2 + \ln(n!) + \mathcal{O}(n^{-3/2}).$$

Also,

$$\begin{aligned} S^{(2)}(\tilde{z}) &= n^3/36 + (1/24 - 3/100x^2)n^2 + \mathcal{O}(n^{3/2}), \\ S^{(3)}(\tilde{z}) &= \mathcal{O}(n^{7/2}), \\ S^{(4)}(\tilde{z}) &= -n^5/600 + \mathcal{O}(n^4), \\ S^{(l)}(\tilde{z}) &= \mathcal{O}(n^{l+1}), \quad l \geq 5. \end{aligned}$$

We can now compute (6), for instance by using the classical trick of setting

$$S^{(2)}(\tilde{z})(i\tau)^2/2! + \sum_{l=3}^{\infty} S^{(l)}(\tilde{z})(i\tau)^l/l! = -u^2/2,$$

computing τ as a truncated series in u, setting $d\tau = \frac{d\tau}{du}du$, expanding with respect to n and integrating on $[u = -\infty..\infty]$. (This amounts to the *reversion* of a series.) Finally, (6) leads to

$$J_n \sim e^{-x^2/2}\cdot\exp[(-51/50 + 27/50x^2)/n + \mathcal{O}(n^{-3/2})]/(2\pi n^3/36)^{1/2}. \tag{7}$$

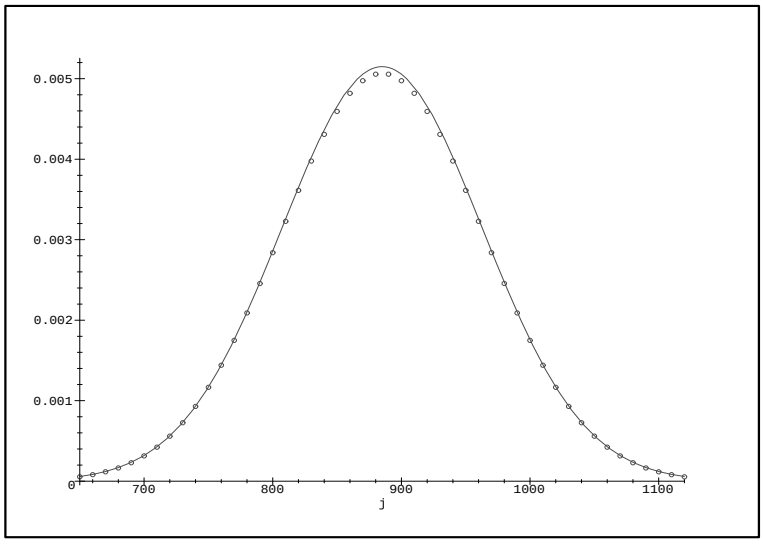

Figure 2: $J_n(j)$ (circle) and the asymptotics (7) (line), without the $1/n$ term, $n = 60$

Note that $S^{(3)}(\tilde{z})$ does not contribute to the $1/n$ correction.

To check the effect of the correction, we first give in Figure 2, for $n = 60$, the comparison between $J_n(j)$ and the asymptotics (7), without the $1/n$ term. Figure 3 gives the same comparison, with the constant term $-51/(50n)$ in the correction. Figure 4 shows the quotient of $J_n(j)$ and the asymptotics (7), with the constant term $-51/(50n)$. The "hat" behaviour, already noticed by Margolius, is apparent. Finally, Figure 5 shows the quotient of $J_n(j)$ and the asymptotics (7), with the full correction.

3 The case $j = n - k$

Figure 6 shows the real part of $S(z)$ as given by (1), together with a path Ω through the saddle point.

It is easy to see that here, we have $z^* = 1/2$. We obtain, to first order,

$$[C_{1,n} - 2j - 2 + 2n] + [C_{2,n} - 4j - 4 - 4n]\varepsilon = 0$$

with

$$\begin{aligned} C_{1,n} &= C_1 + \mathcal{O}(2^{-n}), \\ C_1 &= \sum_{i=1}^{\infty} \frac{-2i}{2^i - 1} = -5.48806777751\ldots, \\ C_{2,n} &= C_2 + \mathcal{O}(2^{-n}), \\ C_2 &= \sum_{i=1}^{\infty} 4\frac{i(i2^i - 2^i + 1)}{(2^i - 1)^2} = 24.3761367267\ldots . \end{aligned}$$

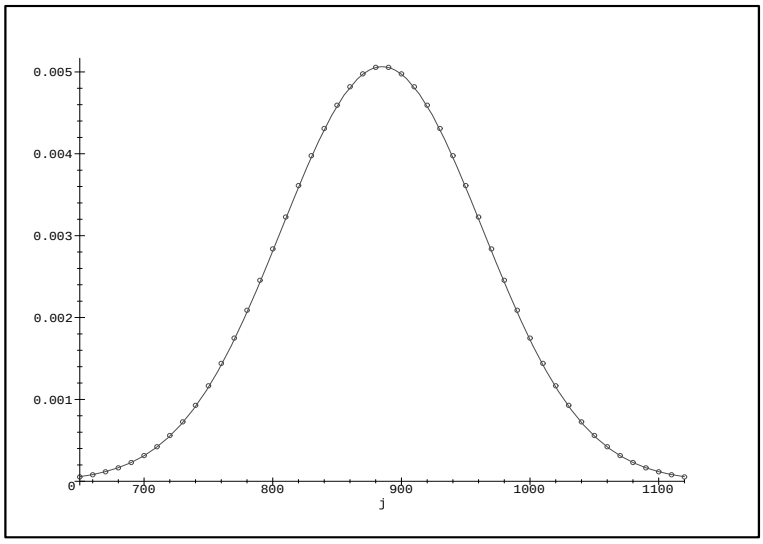

Figure 3: $J_n(j)$ (circle) and the asymptotics (7) (line), with the constant in the $1/n$ term, $n = 60$

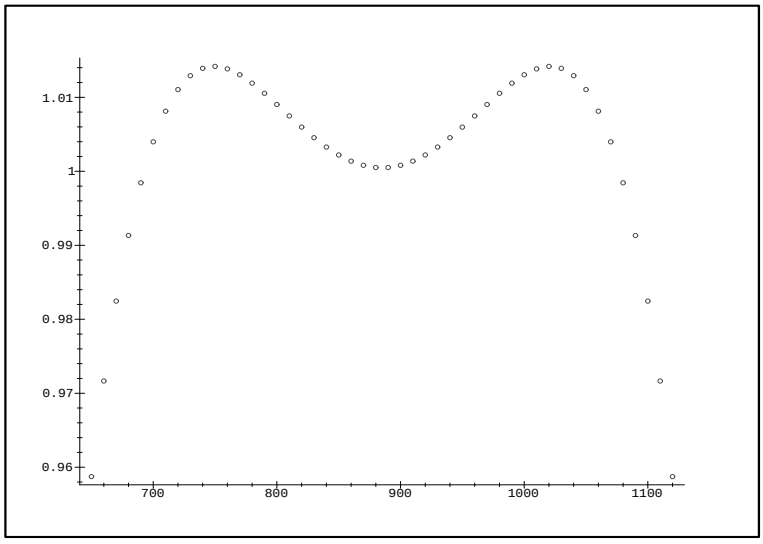

Figure 4: Quotient of $J_n(j)$ and the asymptotics (7), with the constant in the $1/n$ term, $n = 60$

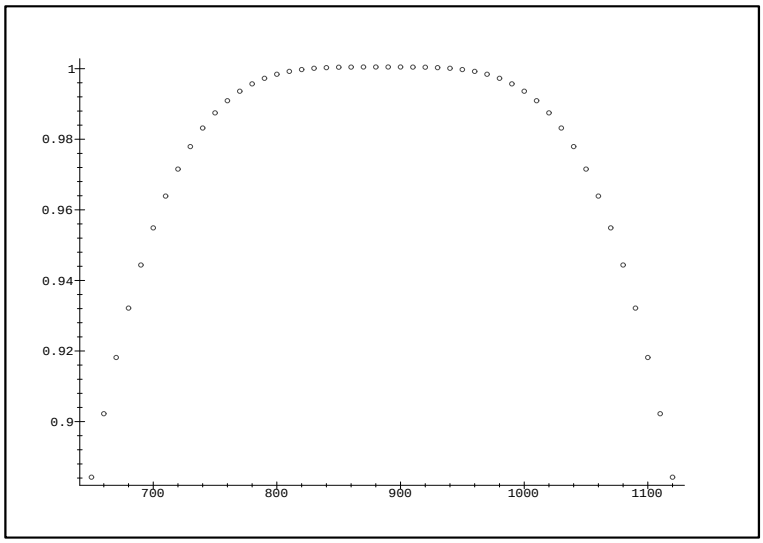

Figure 5: Quotient of $J_n(j)$ and the asymptotics (7), with the full $1/n$ term, $n = 60$

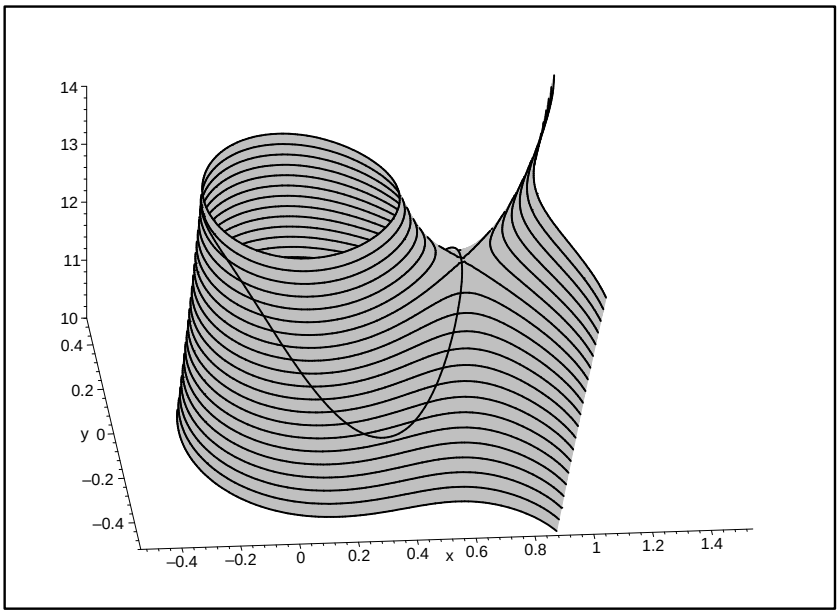

Figure 6: Real part of $S(z)$. Saddle-point and path, $n = 10$, $k = 0$

Set $j = n - k$. This shows that, asymptotically, ε is given by a Laurent series of powers of n^{-1}, starting with $(k - 1 + C_1/2)/(4n)$. Next, we obtain

$$[C_1 - 2j - 2 + 2n] + [C_2 - 4j - 4 - 4n]\varepsilon + [C_3 + 8n - 8j - 8]\varepsilon^2 = 0$$

for some constant C_3. More generally, powers ε^{2k} lead to a $\mathcal{O}(1) \cdot \varepsilon^{2k}$ term, powers ε^{2k+1} lead to a $\mathcal{O}(n) \cdot \varepsilon^{2k+1}$ term. This gives the estimate

$$\varepsilon = (k - 1 + C_1/2)/(4n) + (2k - 2 + C_1)(4k - 4 + C_2)/(64n^2) + \mathcal{O}(1/n^3).$$

Now we derive

$$S_1(\tilde{z}) = \ln(Q) - C_1(k - 1 + C_1/2)/(4n) + \mathcal{O}(1/n^2)$$

with $Q := \prod_{i=1}^{\infty}(1 - 1/2^i) = .288788095086\ldots$. Similarly,

$$S_2(\tilde{z}) = 2\ln(2)n + (1 - k)\ln(2) + (-k^2/2 + k - 1/2 + C_1^2/8)/(2n) + \mathcal{O}(1/n^2)$$

and so

$$S(\tilde{z}) = \ln(Q) + 2\ln(2)n + (1 - k)\ln(2) + (A_0 + A_1 k - k^2/4)/n + \mathcal{O}(1/n^2)$$

with

$$\begin{aligned} A_0 &:= -(C_1 - 2)^2/16, \\ A_1 &:= (-C_1/2 + 1)/2. \end{aligned}$$

Now we turn to the derivatives of S. We will analyze, with some precision, $S^{(2)}$, $S^{(3)}$, $S^{(4)}$ (the exact number of needed terms is defined by the precision we want in the final result). Note that, from $S^{(3)}$ on, only $S_2^{(l)}$ must be computed, as $S_1^{(l)}(\tilde{z}) = \mathcal{O}(1)$. This leads to

$$\begin{aligned} S^{(2)}(\tilde{z}) &= 8n + (-C_2 - 4k + 4) + \mathcal{O}(1/n), \\ S_2^{(3)}(\tilde{z}) &= \mathcal{O}(1), \\ S_2^{(4)}(\tilde{z}) &= 192n + \mathcal{O}(1), \\ S_2^{(l)}(\tilde{z}) &= \mathcal{O}(n), \quad l \geq 5. \end{aligned}$$

We denote by $S^{(2,1)}$ the dominant term of $S^{(2)}(\tilde{z})$, i.e., $S^{(2,1)} := 8n$. We now compute ($S_2^{(3)}(\tilde{z})$ is not necessary here)

$$\frac{1}{2\pi}\exp[S(\tilde{z})]\int_{-\infty}^{\infty}\exp[S^2(\tilde{z})(i\tau)^2/2!]\exp[S^4(\tilde{z})(i\tau)^4/4! + \mathcal{O}(n\tau^5)]d\tau$$

which gives

$$\begin{aligned} I_n(n-k) \;\sim\; & e^{2\ln(2)n + (1-k)\ln(2)}\frac{Q}{(2\pi S^{(2,1)})^{1/2}}\cdot \\ & \exp\left\{\left[(A_0 + 1/8 + C_2/16) + (A_1 + 1/4)k - k^2/4\right]/n + \mathcal{O}(1/n^2)\right\}. \end{aligned} \quad (8)$$

To compare our result with Margolius', we replace n by $n+k$ and find

$$I_{n+k}(n) = \frac{2^{2n+k-1}}{\sqrt{\pi n}}\Big(q_0 - \frac{q_0+q_2-2q_1}{8n} + \frac{(q_0-q_1)k}{4n} - \frac{q_0 k^2}{n} + \mathcal{O}(n^{-2})\Big).$$

We have

$$q_0 = Q = \prod_{i=1}^{\infty}(1-2^{-i}),$$

and

$$q_1 = -2q_0\sum_{i=1}^{\infty}\frac{i}{2^i-1},$$

and

$$\frac{q_2}{2q_0} = -\sum_{i=1}^{\infty}\frac{i(i-1)}{2^i-1} + \Big(\sum_{i=1}^{\infty}\frac{i}{2^i-1}\Big)^2 - \sum_{i=1}^{\infty}\frac{i^2}{(2^i-1)^2}.$$

Margolius' form of the constants follows from Euler's pentagonal theorem, [1]

$$Q(z) = \prod_{i=1}^{\infty}(1-z^i) = \sum_{i\in\mathbb{Z}}(-1)^i z^{\frac{i(3i-1)}{2}}$$

and differentiations:

$$q_1 = \sum_{i\in\mathbb{Z}}(-1)^i i(3i-1)2^{-\frac{i(3i-1)}{2}},$$

respectively,

$$q_2 = \sum_{i\in\mathbb{Z}}(-1)^i i(3i-1)\Big(\frac{i(3i-1)}{2}-1\Big)2^{-\frac{i(3i-1)}{2}}.$$

In our formula, k can be negative as well (which was excluded in Margolius' analysis).

Figure 7 gives, for $n=300$, $I_n(n-k)$ normalized by the first two terms of (8) together with the $1/n$ correction in (8); the result is a bell shaped curve, which is perhaps not too unexpected. Figure 8 shows the quotient of $I_n(n-k)$ and the asymptotics (8).

4 The case $j = \alpha n - x$, $\alpha > 0$

Of course, we must have that $\alpha n - x$ is an integer. For instance, we can choose α, x integers. But this also covers more general cases, for instance $I_{\alpha n+\beta}(\gamma n+\delta)$, with α, β, γ, δ integers. We have here $z^* = \alpha/(1+\alpha)$. We derive, to first order,

$$[C_{1,n}(\alpha) - (j+1)(1+\alpha)/\alpha + (1+\alpha)n] + [C_{2,n}(\alpha) - (j+1)(1+\alpha)^2/\alpha^2 - (1+\alpha)^2 n]\varepsilon = 0$$

with, setting $\varphi(i,\alpha) := [\alpha/(1+\alpha)]^i$,

$$C_{1,n}(\alpha) \;=\; C_1(\alpha) + \mathcal{O}([\alpha/(1+\alpha)]^{-n}),$$

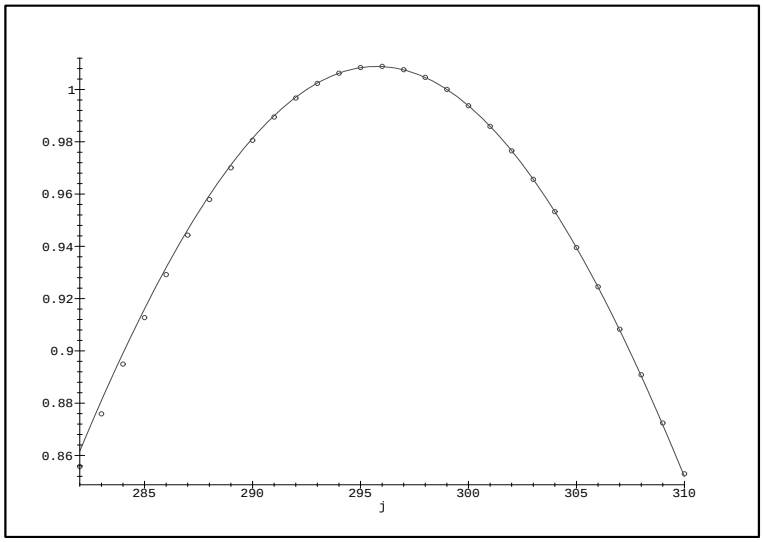

Figure 7: normalized $I_n(n-k)$ (circle) and the $1/n$ term in the asymptotics (8) (line), $n = 300$

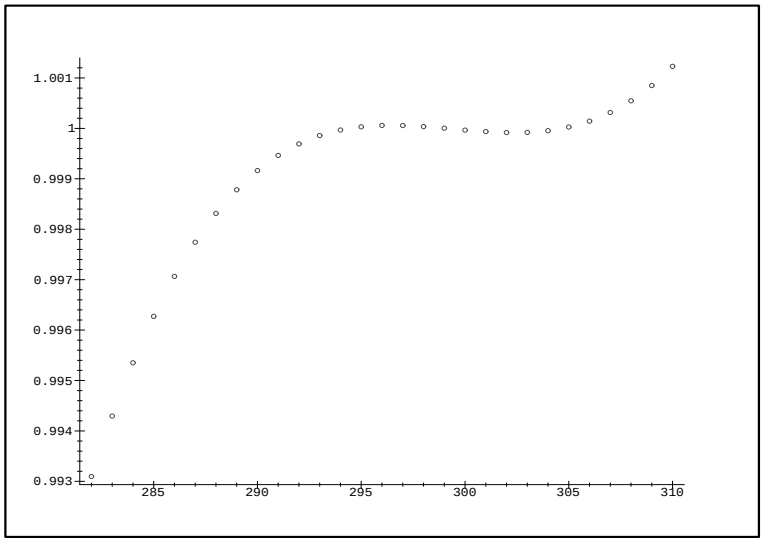

Figure 8: Quotient of $I_n(n-k)$ and the asymptotics (8), $n = 300$

$$
\begin{aligned}
C_1(\alpha) &= \sum_{i=1}^{\infty} \frac{i(1+\alpha)\varphi(i,\alpha)}{\alpha[\varphi(i,\alpha)-1]}, \\
C_{2,n}(\alpha) &= C_2(\alpha) + \mathcal{O}([\alpha/(1+\alpha)]^{-n}), \\
C_2(\alpha) &= \sum_{i=1}^{\infty} \varphi(i,\alpha) i (1+\alpha)^2 (i-1+\varphi(i,\alpha))/[(\varphi(i,\alpha)-1)^2\alpha^2].
\end{aligned}
$$

Set $j = \alpha n - x$. This leads to

$$
\varepsilon = [x + \alpha x - 1 - \alpha + C_1\alpha]/[(1+\alpha)^3 n] + \mathcal{O}(1/n^2).
$$

Next, we obtain

$$
\begin{aligned}
&[C_{1,n}(\alpha) - (j+1)(1+\alpha)/\alpha + (1+\alpha)n] + [C_{2,n}(\alpha) - (j+1)(1+\alpha)^2/\alpha^2 - (1+\alpha)^2 n]\varepsilon \\
&\quad + [C_{3,n}(\alpha) + (1+\alpha)^3 n - (j+1)(1+\alpha)^3/\alpha^3]\varepsilon^2 = 0
\end{aligned}
$$

for some function $C_{3,n}(\alpha)$. More generally, powers ε^k lead to a $\mathcal{O}(n)\cdot\varepsilon^k$ term. This gives

$$
\begin{aligned}
\varepsilon &= [x + \alpha x - 1 - \alpha + C_1\alpha]/[(1+\alpha)^3 n] + (x + x\alpha - 1 - \alpha + C_1\alpha) \times \\
&\qquad \times (x + 2x\alpha + x\alpha^2 - \alpha^2 + C_1\alpha^2 - 2\alpha + C_2\alpha - 1 - C_1)/[(1+\alpha)^6 n^2] + \mathcal{O}(1/n^3).
\end{aligned}
$$

Next we derive

$$
S_1(\tilde{z}) = \ln(\hat{Q}(\alpha)) - C_1[x + \alpha x - 1 - \alpha + C_1\alpha]/[(1+\alpha)^3 n] + \mathcal{O}(1/n^2)
$$

with

$$
\hat{Q}(\alpha) := \prod_{i=1}^{\infty}(1-\varphi(i,\alpha)) = \prod_{i=1}^{\infty}\Big(1 - \Big(\frac{\alpha}{1+\alpha}\Big)^i\Big) = Q\Big(\frac{\alpha}{1+\alpha}\Big).
$$

Similarly

$$
\begin{aligned}
S_2(\tilde{z}) &= [-\ln(1/(1+\alpha)) - \alpha\ln(\alpha/(1+\alpha))]n + (x-1)\ln(\alpha/(1+\alpha)) \\
&\quad + \{(C_1\alpha+\alpha+1)(C_1\alpha-\alpha-1)/[2\alpha(1+\alpha)^3] + x/[\alpha(1+\alpha)] \\
&\quad - x^2/[2\alpha(1+\alpha)]\}/n + \mathcal{O}(1/n^2).
\end{aligned}
$$

So

$$
\begin{aligned}
S(\tilde{z}) &= [-\ln(1/(1+\alpha)) - \alpha\ln(\alpha/(1+\alpha))]n + \ln(\hat{Q}(\alpha)) + (x-1)\ln(\alpha/(1+\alpha)) \\
&\quad + \{-(C_1\alpha-\alpha-1)^2/[2\alpha(1+\alpha)^3] - x(C_1\alpha-\alpha-1)/[\alpha(1+\alpha)^2] - x^2/[2\alpha(1+\alpha)]\}/n \\
&\quad + \mathcal{O}(1/n^2).
\end{aligned}
$$

The derivatives of S are computed as follows:

$$
\begin{aligned}
S^{(2)}(\tilde{z}) &= (1+\alpha)^3/\alpha n - (2x\alpha^3 + 2C_1\alpha^3 - 2\alpha^3 + C_2\alpha^2 + 3x\alpha^2 - 3\alpha^2 - 2C_1\alpha - x + 1)/\alpha^2 + \mathcal{O}(1/n), \\
S_2^{(3)}(\tilde{z}) &= 2(1+\alpha^3)(\alpha^2-1)/\alpha^2 n + \mathcal{O}(1), \\
S_2^{(4)}(\tilde{z}) &= 6(1+\alpha)^4(\alpha^3+1)/\alpha^3 n + \mathcal{O}(1), \\
S_2^{(l)}(\tilde{z}) &= \mathcal{O}(n), \quad l \geq 5.
\end{aligned}
$$

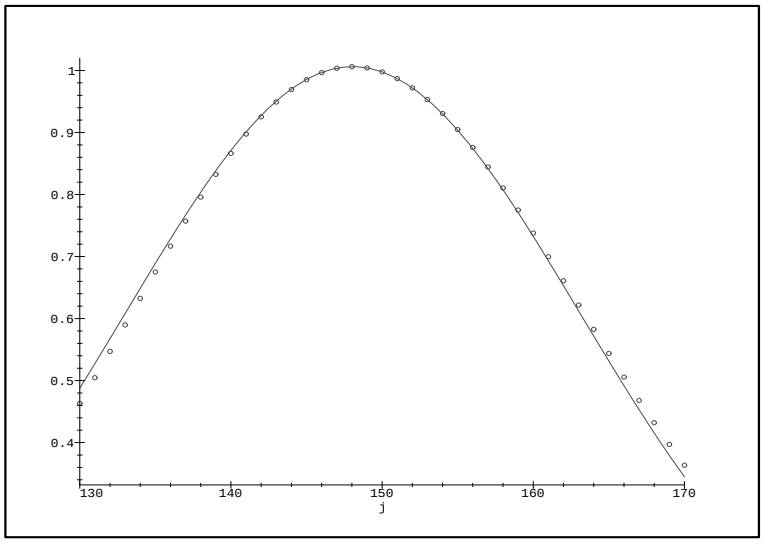

Figure 9: normalized $I_n(\alpha n - x)$ (circle) and the $1/n$ term in the asymptotics (10) (line), $\alpha = 1/2$, $n = 300$

We denote by $S^{(2,1)}$ the dominant term of $S^{(2)}(\tilde{z})$, e.g., $S^{(2,1)} := n(1+\alpha)^3/\alpha$. Note that, now, $S_2^{(3)}(\tilde{z}) = \mathcal{O}(n)$, so we cannot ignore its contribution. Of course, $\mu_3 = 0$ (third moment of the Gaussian), but $\mu_6 \neq 0$, so $S_2^{(3)}(\tilde{z})$ contributes to the $1/n$ term. Finally, Maple gives us

$$\begin{aligned} I_n(\alpha n - x) \quad \sim \quad & e^{[-\ln(1/(1+\alpha)) - \alpha \ln(\alpha/(1+\alpha))]n + (x-1)\ln(\alpha/(1+\alpha))} \frac{\hat{Q}(\alpha)}{(2\pi S^{(2,1)})^{1/2}} \times \\ & \times \exp[\{-(1+3\alpha+4\alpha^2-12\alpha^2 C_1 + 6C_1^2\alpha^2 + \alpha^4 + 3\alpha^3 - 6C_2\alpha^2 \\ & -12C_1^3\alpha)/[12\alpha(1+\alpha)^3]\}] \\ & +x(2\alpha^2 - 2C_1\alpha + 3\alpha + 1)/[2\alpha(1+\alpha)^2] - x^2/[2\alpha(1+\alpha)]\} /n + \mathcal{O}(1/n^2)] \,. \end{aligned} \tag{9}$$

Figure 9 gives, for $\alpha = 1/2$, $n = 300$, $I_n(\alpha n - x)$ normalized by the first two terms of (10) together with the $1/n$ correction in (10). Figure 10 shows the quotient of $I_n(\alpha n - x)$ and the asymptotics (10).

5 The moderate Large deviation, $j = m + xn^{7/4}$

Now we consider the case $j = m + xn^{7/4}$. We have here $z^* = 1$. We observe the same behaviour as in Section 2 for the coefficients of ε in the generalization of (4).

Proceeding as before, we see that asymptotically, ε is now given by a Puiseux series of powers of $n^{-1/4}$, starting with $-36x/n^{5/4}$. This leads to

$$\varepsilon = -36x/n^{5/4} - 1164/25x^3/n^{7/4} + (-240604992/30625x^5 + 54x)/n^{9/4} + F_1(x)/n^{5/2} + \mathcal{O}(n^{-11/4}),$$

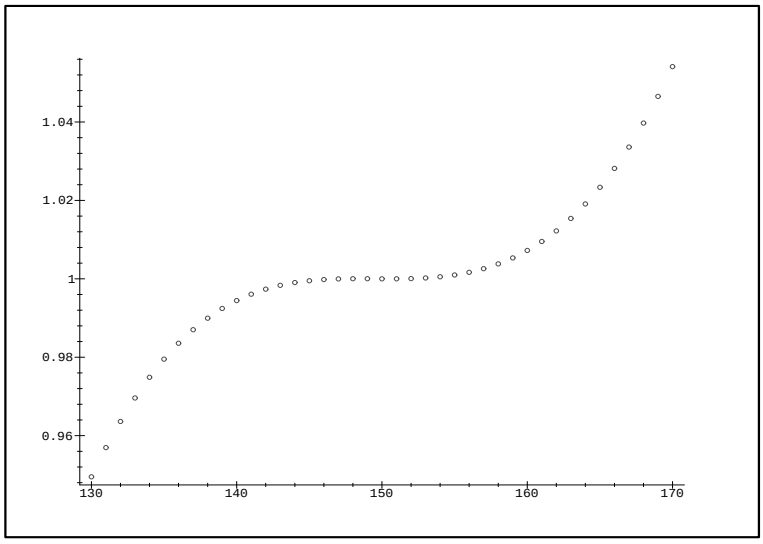

Figure 10: Quotient of $I_n(\alpha n - x)$ and the asymptotics (10), $\alpha = 1/2$, $n = 300$

where F_1 is an (unimportant) polynomial of x. This leads to

$$\begin{aligned} S(\tilde{z}) &= \ln(n!) - 18x^2\sqrt{n} - 2916/25x^4 - 27/625x^2(69984x^4 - 625)/\sqrt{n} \\ &\quad - 1458/15625x^4(-4375 + 1259712x^4)/n + \mathcal{O}(n^{-5/4}). \end{aligned}$$

Also,

$$\begin{aligned} S^{(2)}(\tilde{z}) &= n^3/36 + (1/24 + 357696/30625x^4)n^2 - 27/25x^2n^{5/2} + \mathcal{O}(n^{7/4}), \\ S^{(3)}(\tilde{z}) &= -1/12n^3 + \mathcal{O}(n^{15/4}), \\ S^{(4)}(\tilde{z}) &= -n^5/600 + \mathcal{O}(n^{9/2}), \\ S^{(l)}(\tilde{z}) &= \mathcal{O}(n^{l+1}), \quad l \geq 5, \end{aligned}$$

and finally we obtain

$$\begin{aligned} J_n &\sim e^{-18x^2\sqrt{n} - 2916/25x^4} \times \\ &\quad \times \exp\Big[x^2(-1889568/625x^4 + 1161/25)/\sqrt{n} \\ &\quad + (-51/50 - 1836660096/15625x^8 + 17637426/30625x^4)/n \\ &\quad + \mathcal{O}(n^{-5/4})\Big]/(2\pi n^3/36)^{1/2}. \end{aligned} \tag{10}$$

Note that $S^{(3)}(\tilde{z})$ does not contribute to the correction and that this correction is equivalent to the Gaussian case when $x = 0$. Of course, the dominant term is null for $x = 0$.

To check the effect of the correction, we first give in Figure 11, for $n = 60$ and $x \in [-1/4..1/4]$, the comparison between $J_n(j)$ and the asymptotics (10), without the $1/\sqrt{n}$ and $1/n$ term. Figure 12 gives the same comparison, with the correction. Figure 13 shows the

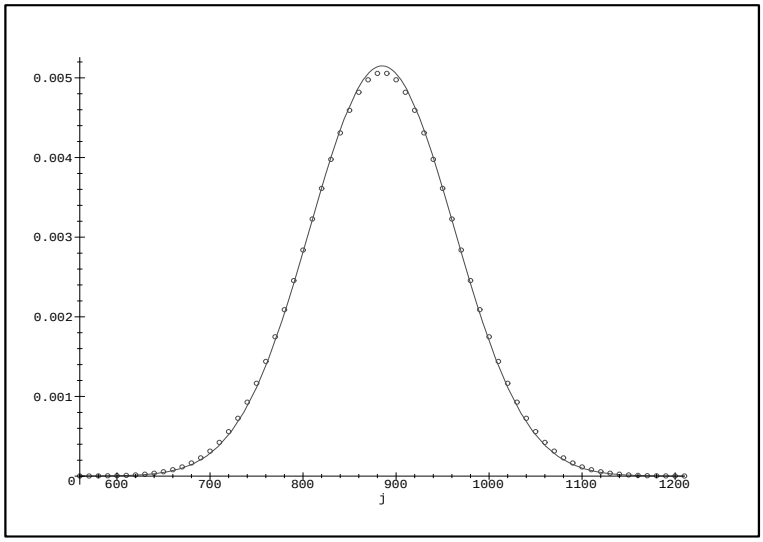

Figure 11: $J_n(j)$ (circle) and the asymptotics (10) (line), without the $1/\sqrt{n}$ and $1/n$ term, $n = 60$

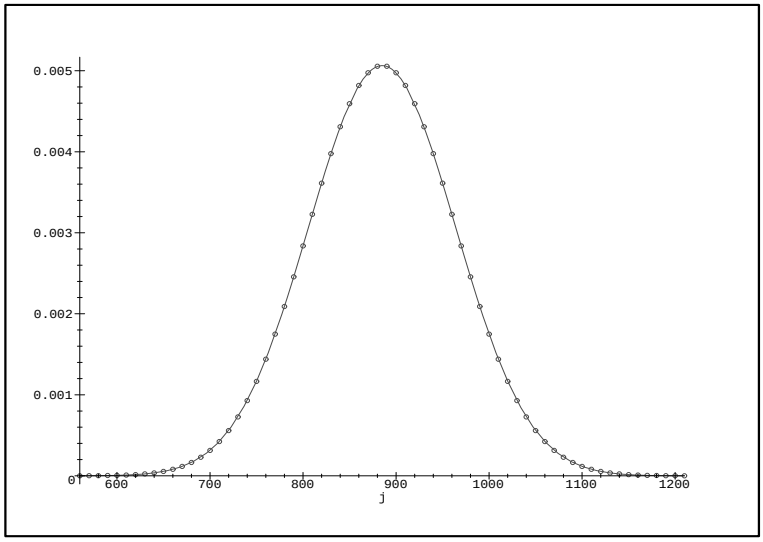

Figure 12: $J_n(j)$ (circle) and the asymptotics (10) (line), with the $1/\sqrt{n}$ and $1/n$ term, $n = 60$

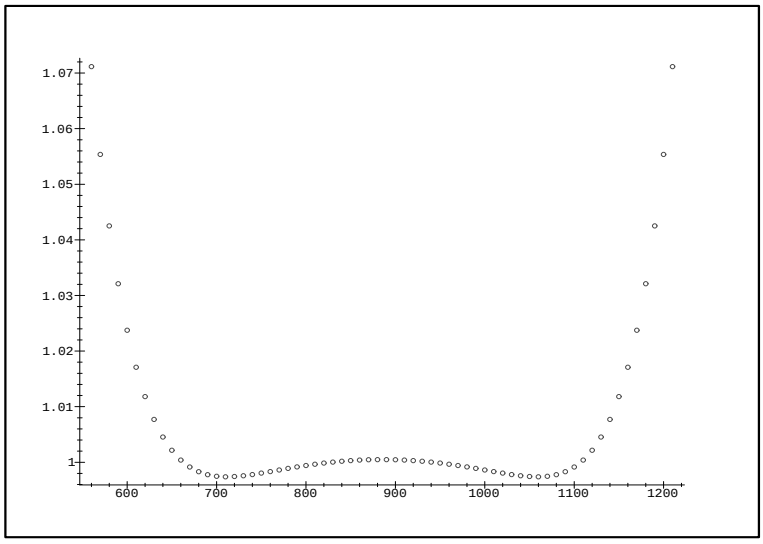

Figure 13: Quotient of $J_n(j)$ and the asymptotics (10), with the $1/\sqrt{n}$ and $1/n$ term, $n = 60$

quotient of $J_n(j)$ and the asymptotics (10), with the $1/\sqrt{n}$ and $1/n$ term.

The exponent 7/4 that we have chosen is of course not sacred; any fixed number below 2 could also have been considered.

6 Large deviations, $j = \alpha n(n-1)$, $0 < \alpha < 1/2$

Here, again, $z^* = 1$. Asymptotically, ε is given by a Laurent series of powers of n^{-1}, but here the behaviour is quite different: *all* terms of the series generalizing (4) contribute to the computation of the coefficients. It is convenient to analyze separately $S_1^{(1)}$ and $S_2^{(1)}$. This gives, by substituting

$$\tilde{z} := 1 - \varepsilon,\ j = \alpha n(n-1),\ \varepsilon = a_1/n + a_2/n^2 + a_3/n^3 + \mathcal{O}(1/n^4),$$

and expanding with respect to n,

$$\begin{aligned} S_2^{(1)}(\tilde{z}) &\sim (1/a_1 - \alpha)n^2 + (\alpha - \alpha a_1 - a_2/a_1^2)n + \mathcal{O}(1), \\ S_1^{(1)}(\tilde{z}) &\sim \sum_{k=0}^{n-1} f(k), \end{aligned}$$

where

$$\begin{aligned} f(k) &:= -(k+1)(1-\varepsilon)^k/[1-(1-\varepsilon)^{k+1}] \\ &= -(k+1)(1-[a_1/n + a_2/n^2 + a_3/n^3 + \mathcal{O}(1/n^4)])^k \\ &\quad /\{1-(1-[a_1/n + a_2/n^2 + a_3/n^3 + \mathcal{O}(1/n^4)])^{k+1}\}. \end{aligned}$$

This immediately suggests to apply the Euler-Mac Laurin summation formula, which gives, to first order,

$$S_1^{(1)}(\tilde{z}) \sim \int_0^n f(k)dk - \frac{1}{2}(f(n) - f(0)),$$

so we set $k = -un/a_1$ and expand $-f(k)n/a_1$. This leads to

$$\begin{aligned}\int_0^n f(k)dk &\sim \int_0^{-a_1} \left[-\frac{ue^u}{a_1^2(1-e^u)}n^2 + \frac{e^u[2a_1^2 - 2e^u a_1^2 - 2u^2 a_2 - u^2 a_1^2 + 2e^u u a_1^2]}{2a_1^3(1-e^u)^2}n\right] du + \mathcal{O}(1) \\ &\quad -\frac{1}{2}(f(n) - f(0)) \\ &\sim \left(\frac{e^{-a_1}}{2(1-e^{-a_1})} - \frac{1}{2a_1}\right) n + \mathcal{O}(1).\end{aligned}$$

This readily gives

$$\begin{aligned}\int_0^n f(k)dk &\sim -\mathrm{dilog}(e^{-a_1})/a_1^2 n^2 \\ &+ [2a_1^3 e^{-a_1} + a_1^4 e^{-a_1} - 4a_2 \mathrm{dilog}(e^{-a_1}) + 4a_2 \mathrm{dilog}(e^{-a_1})e^{-a_1} \\ &+ 2a_2 a_1^2 e^{-a_1} - 2a_1^2 + 2a_1^2 e^{-a_1}]/[2a_1^3(e^{-a_1} - 1)]n + \mathcal{O}(1).\end{aligned}$$

Combining $S_1^{(1)}(\tilde{z}) + S_2^{(1)}(\tilde{z}) = 0$, we see that $a_1 = a_1(\alpha)$ is the solution of

$$-\mathrm{dilog}(e^{-a_1})/a_1^2 + 1/a_1 - \alpha = 0.$$

We check that $\lim_{\alpha\to 0} a_1(\alpha) = \infty$, $\lim_{\alpha\to 1/2} a_1(\alpha) = -\infty$.

Similarly, $a_2(\alpha)$ is the solution of the linear equation

$$\begin{aligned}&\alpha - \alpha a_1 - a_2/a_1^2 + e^{-a_1}/[2(1-e^{-a_1})] - 1/(2a_1) \\ +\ &[2a_1^3 e^{-a_1} + a_1^4 e^{-a_1} + 4a_2 \mathrm{dilog}(e^{-a_1})(e^{-a_1} - 1) + 2a_2 a_1^2 e^{-a_1} - 2a_1^2 + 2a_1^2 e^{-a_1}]/[2a_1^3(e^{-a_1} - 1)] \\ =\ &0\end{aligned}$$

and $\lim_{\alpha\to 0} a_2(\alpha) = -\infty$, $\lim_{\alpha\to 1/2} a_2(\alpha) = \infty$.

We could proceed in the same manner to derive $a_3(\alpha)$ but the computation becomes quite heavy. So we have computed an approximate solution $\tilde{a}_3(\alpha)$ as follows: we have expanded $S^{(1)}(\tilde{z})$ into powers of ε up to ε^{19}. Then an asymptotic expansion into n leads to a n^0 coefficient which is a polynomial of a_1 of degree 19 (of degree 2 in a_2 and linear in a_3). Substituting $a_1(\alpha)$, $a_2(\alpha)$ immediately gives $\tilde{a}_3(\alpha)$. This approximation is satisfactory for $\alpha \in [0.15..0.35]$. Note that $a_1(1/4) = 0$, $a_2(1/4) = 0$ as expected, and $a_3(1/4) = -36$. We obtain

$$\begin{aligned}S(\tilde{z}) &= \ln(n!) + [1/72a_1(a_1 - 18 + 72\alpha)]n \\ &+ [1/72a_1^3 - 1/4a_2 + 1/4a_1 - a_1\alpha - 5/48a_1^2 + 1/36a_1a_2 + a_2\alpha + 1/2a_1^2\alpha] \\ &+ [1/72a_2^2 + 1/36a_1a_3 - 1/4a_3 + 1/4a_2 + a_1 + a_3\alpha + a_1a_2\alpha + 1/3a_1^3\alpha \\ &- a_2\alpha - 1/2a_1^2\alpha - 5/24a_1a_2 + 1/24a_1^2a_2 + 13/144a_1^2 - 1/16a_1^3]/n + \mathcal{O}(1/n^2).\end{aligned}$$

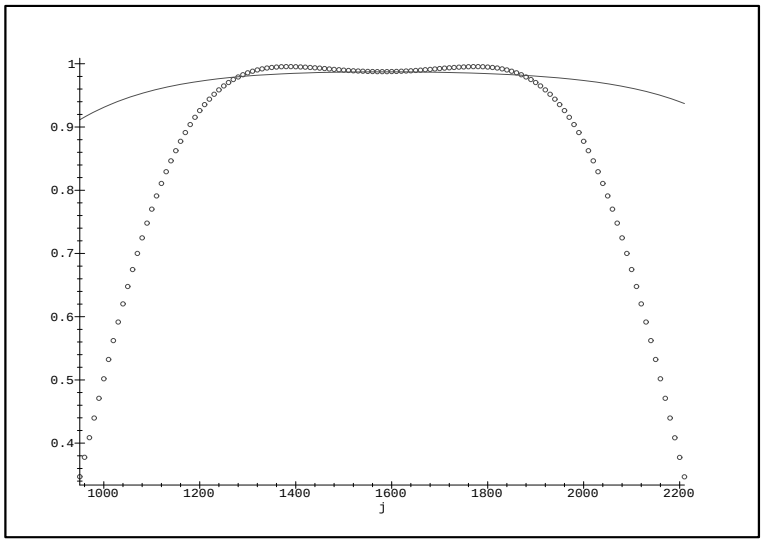

Figure 14: normalized $J_n(\alpha n(n-1))$ (circle) and the $1/n$ term in the asymptotics (11) (line), $n = 80$

Note that the three terms of $S(\tilde{z})$ are null for $\alpha = 1/4$, as expected. This leads to

$$\begin{aligned} S^{(2)}(\tilde{z}) &= n^3/36 + (-5/24 + 1/12a_1 + \alpha)n^2 + \mathcal{O}(n), \\ S^{(3)}(\tilde{z}) &= 1/600a_1 n^4 + \mathcal{O}(n^3), \\ S^{(4)}(\tilde{z}) &= -n^5/600 + \mathcal{O}(n^4), \\ S_2^{(l)}(\tilde{z}) &= \mathcal{O}(n^{l+1}), \quad l \geq 5. \end{aligned}$$

Finally,

$$\begin{aligned} & J_n(\alpha n(n-1)) \\ \sim\ & e^{[1/72a_1(a_1-18+72\alpha)]n+[1/72a_1^3-1/4a_2+1/4a_1-a_1\alpha-5/48a_1^2+1/36a_1a_2+a_2\alpha+1/2a_1^2\alpha]} \frac{1}{(2\pi n^3/36)^{1/2}} \times \\ & \times \exp[(1/72a_2^2 + 1/36a_1a_3 - 1/4a_3 + 1/4a_2 - 1/2a_1 + a_3\alpha + a_1a_2\alpha + 1/3a_1^3\alpha - a_2\alpha \\ -\ & 1/2a_1^2\alpha - 5/24a_1a_2 + 1/24a_1^2a_2 + 1139/18000a_1^2 - 1/16a_1^3 + 87/25 - 18\alpha)/n \\ & + \mathcal{O}(1/n^2)]. \end{aligned} \tag{11}$$

Note that, for $\alpha = 1/4$, the $1/n$ term gives $-51/50$, again as expected.

Figure 14 gives, for $n = 80$ and $\alpha \in [0.15..0.35]$, $J_n(\alpha n(n-1))$ normalized by the first two terms of (11) together with the $1/n$ correction in (11). Figure 15 shows the quotient of $J_n(\alpha n(n-1))$ and the asymptotics (11).

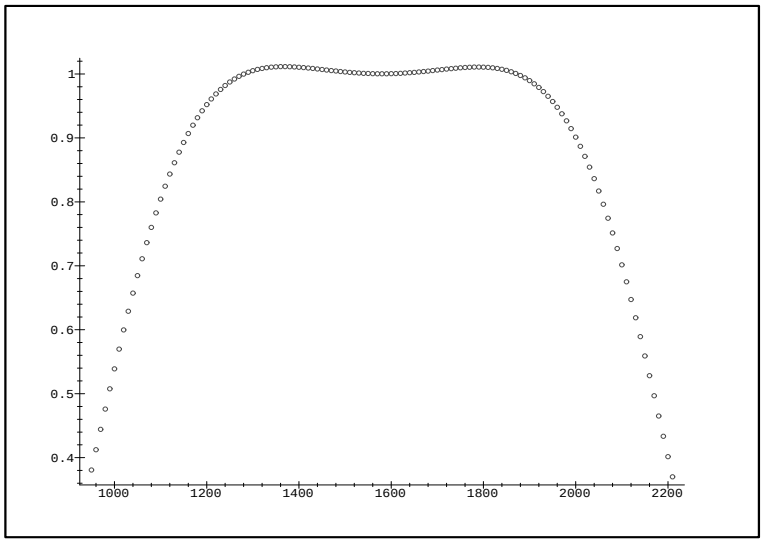

Figure 15: Quotient of $J_n(\alpha n(n-1))$ and the asymptotics (11), $n = 80$

7 Conclusion

Once more the *saddle point method* revealed itself as a powerful tool for asymptotic analysis. With careful human guidance, the computational operations are almost automatic, and can be performed to any degree of accuracy with the help of some computer algebra, at least in principle. This allowed us to include correction terms in our asymptotic formulæ, where we have covered all ranges of interest and one can see their effect in the figures displayed.

An interesting open problem would be to extend our results to $q-$analogues (see, for instance, [6]).

Abstract

The interval from 10^{15} to 5×10^{16} was searched for first occurrence prime gaps and maximal prime gaps. One hundred and twenty-two new first occurrences were found, including four new maximal gaps, leaving 1048 as the smallest gap whose first occurrence remains uncertain. The first occurrence of any prime gap of 1000 or greater was found to be the maximal gap of 1132 following the prime 1693182318746371. A maximal gap of 1184 follows the prime 43841547845541059. More extensive tables of prime gaps are maintained at http://www.trnicely.net.

1. Introduction

We restrict our discussion to the positive integers. Let Q denote the sequence of prime numbers, $Q = \{2, 3, 5, 7, 11, \ldots, q_k, q_{k+1}, \ldots\}$, and D the sequence of differences of consecutive prime numbers, $D = \{1, 2, 2, 4, \ldots, q_{k+1} - q_k, \ldots\}$.

A *prime gap* G is the interval bounded by two consecutive prime numbers q_k and q_{k+1}. The *measure* (size, magnitude) g of a prime gap G is the difference $g = q_{k+1} - q_k$ of its bounding primes. A prime gap is often specified by its measure g and its initial prime $p_1 = q_k$, and less often by the measure g and the terminal prime $p_2 = q_{k+1}$. A prime gap of measure g contains $g - 1$ consecutive composite integers. The measures of the prime gaps are the

[1] Corresponding author.

successive elements of the sequence D. Since 2 is the only even prime, every prime gap is of even measure, with the sole exception of the prime gap of measure 1 following the prime 2.

In illustration, a gap of measure $g = 6$ (or simply a gap of 6) follows the prime $p_1 = 23$, while a gap of 10 follows the prime 139.

It is elementary that gaps of arbitrarily large measure exist, since, as observed by Lucas [11], for $n > 0$ the integer $(n+1)! + 1$ must be followed by at least n consecutive composites, divisible successively by $2, 3, \ldots, n+1$; however, $n+1$ represents only a lower bound on the measure of such gaps.

The *merit* M of a prime gap of measure g following the prime p_1 is defined as $M = g/\ln(p_1)$. It is the ratio of the measure of the gap to the "average" measure of gaps near that point; as a consequence of the Prime Number Theorem, the average difference between consecutive primes near x is approximately $\ln(x)$.

A prime gap of measure g is considered a *first occurrence prime gap* when no smaller consecutive primes differ by exactly g, i.e., when this is the first appearance of the positive integer g in the sequence D. Thus, the gap of 4 following 7 is a first occurrence, while the gap of 4 following 13 is not. Note that this usage of the compound adjective *first occurrence* carries no implication whatsoever regarding historical precedence of discovery. Multiple instances of gaps of 1048 are known, but none is yet known to be a first occurrence, even though one of them bears an earliest historical date of discovery. This terminology follows that of Young and Potler [20], and produces more concise phrasing than some past and present alternative nomenclature.

A prime gap of measure g is titled *maximal* if it strictly exceeds all preceding gaps, i.e., the difference between any two consecutive smaller primes is $< g$, so that g exceeds all preceding elements of D. Thus the gap of 6 following the prime 23 is a maximal prime gap, since each and every smaller prime is followed by a gap less than 6 in measure; but the gap of 10 following the prime 139, while a first occurrence, is not maximal, since a larger gap (the gap of 14 following the prime 113) precedes it in the sequence of integers. Maximal prime gaps are *ipso facto* first occurrence prime gaps as well.

Furthermore, the term *first known occurrence prime gap* is used to denote a prime gap of measure g which has not yet been proven to be (and may or may not be) the true first occurrence of a gap of measure g; this situation arises from an incomplete knowledge of the gaps (and primes) below the first known occurrence. Thus, Nyman discovered a gap of 1048 following the prime 88089672331629091, and no smaller instance is known; but since his exhaustive scan extended only to 5×10^{16}, this gap remains for the moment merely a first known occurrence, not a first occurrence. First known occurrences serve as upper bounds for first occurrences not yet established.

The search for first occurrence and maximal prime gaps was previously extended to 10^{15} by the works of Glaisher [7], Western [18], Lehmer [10], Appel and Rosser [1], Lander and Parkin [9], Brent [2, 3], Young and Potler [20], and Nicely [12]. The present work extends this upper bound to 5×10^{16}. The calculations are currently being continued beyond 5×10^{16} by Tomás Oliveira e Silva [17], as part of a project generating numerical evidence for the Goldbach conjecture.

2. Computational Technique

The calculations were carried out over a period of years, distributed asynchronously among numerous personal computers, taking advantage of otherwise idle CPU time. Nyman accomplished the bulk of the computations; employing as many as eighty systems from 1998 to 2002, he accounted for the survey of the region from $1.598508912 \times 10^{15}$ through 5×10^{16}. Nicely's enumerations of prime gaps began in the summer of 1995, but the portion reported here was carried out from 1997 to 1999, over the interval from 10^{15} to $1.598508912 \times 10^{15}$, the number of systems in use varying from about five to twenty-five. The algorithms employed the classic sieve of Eratosthenes, with the addition of a few speed enhancing optimizations, to carry out an exhaustive generation and analysis of the differences between consecutive primes. More sophisticated techniques for locating large prime gaps, such as scanning through arithmetic progressions, were rendered impractical by the fact that the search for first occurrences was being carried out concurrently with other tasks; Nicely was enumerating prime constellations, while Nyman was gathering comprehensive statistics on the frequency distribution of prime gaps.

Among the measures taken to guard against errors (whether originating in logic, software, or hardware), the count $\pi(x)$ of primes was maintained and checked periodically against known values, such as those published by Riesel [14], and especially the extensive values computed recently by Silva [17]. In addition, Nicely has since duplicated Nyman's results through 4.5×10^{15}.

3. Computational Results

Table 3 lists the newly discovered first occurrence prime gaps resulting from the present study; maximal gaps are indicated by a double dagger (‡). Each table entry shows the measure g of the gap and the initial prime p_1. The fifteen gaps between 10^{15} and $1.598508912 \times 10^{15}$ are due to Nicely; all the rest were discovered by Nyman.

4. Observations

As a collateral result of his calculations, Nyman has computed for the count of twin primes the value $\pi_2(5 \times 10^{16}) = 47177404870103$, the maximum argument for which this function has been evaluated. Nyman also obtained $\pi(5 \times 10^{16}) = 1336094767763971$ for the corresponding count of primes; this is the largest value of x for which $\pi(x)$ has been determined by direct enumeration, and confirms the value previously obtained by Deléglise and Rivat [5], using indirect sieving methods. Nyman has also generated frequency tables for the distribution of all prime gaps below 5×10^{16}.

Listings of the 423 previously known first occurrence prime gaps (including 61 maximal gaps), those below 10^{15}, have been published collectively by Young and Potler [20] and Nicely [12], and are herein omitted for brevity.

A comprehensive listing of first occurrence and maximal prime gaps, annotated with additional information, is available at Nicely's URL. Nicely also maintains at his URL extensive lists of first known occurrence prime gaps, lying beyond the present upper bound of exhaustive computation, and discovered mostly by third parties, notably Harvey Dubner [6]. These lists exhibit specific gaps for every even positive integer up to 10884, as well as for other scattered even integers up to 233822; for some of the gaps exceeding 8000 in magnitude, the

Table 1. First occurrence prime gaps between 10^{15} and 5×10^{16}. ‡ denotes a maximal gap

bounding integers have only been proved strong probable primes (based on multiple Miller's tests).

The largest gap herein established as a first occurrence is the maximal gap of 1184 following the prime 43841547845541059, discovered 31 August 2002 by Nyman. The smallest gap whose first occurrence remains uncertain is the gap of 1048.

The maximal gap of 1132 following the prime 1693182318746371, discovered 24 January 1999 by Nyman, is the first occurrence of any "kilogap", i.e., any gap of measure 1000 or greater. Its maximality persists throughout an extraordinarily large interval; the succeeding maximal gap is the gap of 1184 following the prime 43841547845541059. The ratio of the initial primes of these two successive maximal gaps is ≈ 25.89, far exceeding the previous extreme ratio of ≈ 7.20 for the maximal gaps of 34 (following 1327) and 36 (following 9551), each discovered by Glaisher [7] in 1877. Furthermore, the gap of 1132 has the greatest merit (≈ 32.28) of any known gap; the maximal gap of 1184 is the only other one below 5×10^{16} having a merit of 30 or greater.

The gap of 1132 is also of significance to the related conjectures put forth by Cramér [4] and Shanks [16], concerning the ratio $g/\ln^2(p_1)$. Shanks reasoned that its limit, taken over all first occurrences, should be 1; Cramér argued that the limit superior, taken over all prime gaps, should be 1. Granville [8], however, provides evidence that the limit superior is $\geq 2e^{-\gamma} \approx 1.1229$. For the 1132 gap, the ratio is ≈ 0.9206, the largest value observed for any $p_1 > 7$, the previous best being ≈ 0.8311 for the maximal gap of 906 following the prime 218209405436543, discovered by Nicely [12] in February, 1996.

Several models have been proposed in an attempt to describe the distribution of first occurrence prime gaps, including efforts by Western [18], Cramér [4], Shanks [16], Riesel [14], Rodriguez [15], Silva [17], and Wolf [19]. We simply note here Nicely's empirical observation that all first occurrence and maximal prime gaps below 5×10^{16} obey the following relationship:

$$0.122985 \cdot \sqrt{g} \cdot \exp\sqrt{g} \;<\; p_1 \;<\; 2.096 \cdot g \cdot \exp\sqrt{g} \quad . \tag{1}$$

The validity of (1) for *all* first occurrence prime gaps remains a matter of speculation. Among its corollaries would be the conjecture that every positive even integer represents the difference of some pair of consecutive primes, as well as a fairly precise estimate for the answer to the question posed in 1964 by Paul A. Carlson to Daniel Shanks [16], to wit, the location of the first occurrence of one million consecutive composite numbers. The argument $g = 1000002$ entered into (1) yields the result $2.4 \times 10^{436} < p_1 < 4.2 \times 10^{440}$, which is near the middle of Shanks' own estimate of $10^{300} < p_1 < 10^{600}$.

5. Acknowledgments

Nyman wishes to thank SaabTech Systems AB for providing excellent computing facilities.

New Lower Bound On The Number of Ternary Square-Free Words

Xinyu Sun

Abstract

A new lower bound on the number of n-letter ternary square-free words is presented: $110^{n/42}$, which improves the previous best result of $65^{n/40}$.

1. Introduction

A word w is a finite sequence of letters from a certain alphabet Σ. The length of a word is the number of letters of the word. Binary words are the words from a two-letter alphabet {0, 1}, whereas ternary words are from a three-letter alphabet {0, 1, 2}. A word is square-free if it does not contain two identical consecutive subwords (factors), i.e., w cannot be written as $axxb$ where a, b, x are words with x non-empty.

It is easy to see that there are only finitely many binary square-free words. However, there are infinitely many ternary square-free words. The fact was proved by utilizing what is now called the Prouhet-Thue-Morse sequence (see [10]). Brinkhuis[3], Brandenburg[2] (also in [1]), Zeilberger[5] and Grimm[8] showed that the numbers of such words of length n are greater than $2^{n/24}$, $2^{n/21}$, $2^{n/17}$, and $65^{n/40}$ respectively. Details on words and related topics can be found in [6] and [11].

While the best available upper bound has been very close to the estimate as described later, the available lower bounds still have much room for improvement. Finding better lower bounds has posed as a algorithmic challenge, as well as a theoretic one. As explained later, the complexity of the algorithm used here is likely (very) exponential.

2. Brinkhuis Triples

We denote $a(n)$ to be the number of ternary square-free words of length n. It is easy to see that

$$a(m+n) \leq a(m)a(n) \tag{2.1}$$

for all $m,\ n \geq 0$, which implies (see in [1]) the existence of the limit

$$s := \lim_{n\to\infty} a(n)^{1/n}, \tag{2.2}$$

which is also called the growth rate or "connective constant" of ternary square-free words.

It is widely believed that the available upper bounds are very close to the actual value of s. In fact, it has been estimated by Noonan and Zeilberger [7] that $s \approx 1.302$ using the Zinn-Justin method, and they have also proved that $s \leq 1.30201064$ by implementing the Golden-Jackson method.

Definition 1. An n-Brinkhuis k-triple is three sets of words $\mathcal{B} = \{\mathcal{B}^0, \mathcal{B}^1, \mathcal{B}^2\}$, $\mathcal{B}^i = \{w_j^i | 1 \leq j \leq k\}$, where w_j^i are square-free words of length n, such that for any square-free word $i_1 i_2 i_3$, $0 \leq i_1, i_2, i_3 \leq 2$, and any $1 \leq j_1, j_2, j_3 \leq k$, the word $w_{j_1}^{i_1} w_{j_2}^{i_2} w_{j_3}^{i_3}$ of length $3n$ is also square-free.

Based on an n-Brinkhuis k-triple, we can define the following set of uniformly growing morphisms:

$$\rho = \begin{cases} 0 \to w_{j_0}^0,\ 1 \leq j_0 \leq k; \\ 1 \to w_{j_1}^1,\ 1 \leq j_1 \leq k; \\ 2 \to w_{j_2}^2,\ 1 \leq j_2 \leq k. \end{cases} \tag{2.3}$$

As proven in [2], [4] and [9], ρ are square-free morphisms, i.e., they map each square-free word of length m onto k^m different images of square-free words of length nm.

Therefore, the existence of an n-Brinkhuis k-triple indicates that

$$\frac{a(mn)}{a(m)} \geq k^m \tag{2.4}$$

for any $m \geq 1$, which implies

$$s^{n-1} = \lim_{n\to\infty} \left(\frac{a(mn)}{a(m)}\right)^{1/m} \geq k, \tag{2.5}$$

and thus yields the lower bound of $s \geq k^{1/(n-1)}$.

Given the permutation $\tau = (0,\ 1,\ 2)$, we can have

Definition 2. A quasi-special n-Brinkhuis k-triple is an n-Brinkhuis k-triple such that $\mathcal{B}^1 = \tau(\mathcal{B}^0)$, $\mathcal{B}^2 = \tau(\mathcal{B}^1)$.

Definition 3. A special n-Brinkhuis k-triple is a quasi-special n-Brinkhuis k-triple such that $w \in \mathcal{B}^0$ implies $\overline{w} \in \mathcal{B}^0$, where $\overline{w}$ is the reversion of w.

Grimm[8] was able to construct a special 41-Brinkhuis 65-triple, hence proved $s \geq 65^{1/40}$.

3. Main Results

Definition 4. A word w is admissible if $(w, \tau(w), \tau^2(w))$ is a quasi-special Brinkhuis 1-triple by itself.

Definition 5. An optimal quasi-special (special) n-Brinkhuis k-triple is a quasi-special (special) n-Brinkhuis k-triple such that any quasi-special (special) n-Brinkhuis l-triple has $l \leq k$.

To find the optimal quasi-special n-Brinkhuis triples, we only need to find the set of all admissible words of length n, and its largest subset in which any three words w_1, w_2, w_3 can form a quasi-special n-Brinkhuis 3-triple, i.e., $\{\{w_1, w_2, w_3\}, \{\tau(w_1), \tau(w_2), \tau(w_3)\}, \{\tau^2(w_1), \tau^2(w_2), \tau^2(w_3)\}\}$ is a quasi-special n-Brinkhuis 3-triple. A Maple package was written to calculate such words and sets. The results are listed below.

Proposition 3.1. *Special n-Brinkhuis triples yield the best possible results for each $13 \leq n \leq 20$, and quasi-special Brinkhuis triples do not yield better results than special n-Brinkhuis triples for each $13 \leq n \leq 39$, except 37.*

n	b_1	k_1	b_2	k_2
13	1	1	1	1
14	0	0	0	0
15	0	0	0	0
16	0	0	0	0
17	1	1	1	1
18	1	2	1	2
19	1	1	1	1
20	0	0	0	0
21	0	0	0	0
22	0	0	0	0
23	1	3	1	3
24	5	2	3	2
25	1	5	1	5
26	2	2	2	2
27	1	3	1	3
28	4	4	2	4
29	2	6	2	6
30	1	8	1	8
31	4	7	2	7
32	1	8	1	8
33	1	12	1	12
34	33	10	5	10
35	2	18	2	18
36	1	32	1	32
37	66	32	24	31
38	9	28	3	28
39	1	32	1	32
40			2	48
41			8	65
42			4	76
43			2	110

In the table above, n is the length of the words; b_1 and k_1 are the numbers of all available optimal quasi-special Brinkhuis triples and the numbers of elements in the triples; b_2 and k_2 are those of the special Brinkhuis triples. Notice the numbers of the triples and their sizes

do not always grow as n does, and occasionally there are extraordinary amount of the triples for certain word lengths, i.e., 34 and 37.

Although there are often more choices for the regular and quasi-special Brinkhuis triples than the special Brinkhuis triples as listed above, none of them can be combined to form larger triples. And the exception of $n = 37$ has hardly any significance because the results are superceded by the 36-Brinkhuis 32-triples already. These results strongly suggest that the special Brinkhuis triples will generally yield the best results regardless of n.

It is reasonable to believe that there exist n-Brinkhuis triples that are not quasi-special when $n > 20$, or quasi-special n-Brinkhuis triples that are not special when $n > 39$. However, as explained in the proof of the following proposition, it is vary hard to find such triples due to the complexity.

Proposition 3.2. *The following 43-Brinkhuis 110-triple exists, and thus shows* $s \geq 110^{1/42} = 1.118419\ldots > 65^{1/40} = 1.109999\ldots$*:*

Proof: Each admissible word is of length at least 13 and of the form either $012021\cdots120210$ or $012102\cdots201210$ as proved by Grimm [8]. So we first find all the square-free words of

length $n-12$, attach the two pairs of prefixes and suffixes to these words, then determine if the results are square-free and admissible words, and label them from 1 to m, where m is the total number of such words. The next step is to find all quasi-special (special) Brinkhuis 3-triples and replace the words with the labels we just assigned to them. Thus each triple correspond to a unique ordered list of three different integers, and we have created a set of lists of integers S. Note that if the square-free words of length $n-12$ are known, the rest of the process above only take polynomial time. Now the problem is reduced to find the largest subset T of $\{1,\ldots,m\}$ so that the list of any three elements of T is an element of S. Such a question is obviously NP, because the certificate will be the solution itself, and the time required to verify the certificate will be $O(\binom{n}{3})$, thus polynomial. Fortunately, we are not obliged to tell how long it takes to get the certificate.

We now create a graph G so that each element in S is a vertex of G, and any two vertices are connected if and only if any combination of three different numbers from the two lists can form a quasi-special (special) Brinkhuis 3-triple. For example, if $[1,2,3]$ and $[1,2,4]$ are vertices of the graph, they can be connected if and only if $[1,3,4]$ and $[2,3,4]$ are vertices of the graph too. And in this case, the four vertices will form a complete graph. Now we have reduced the problem into finding the largest complete subgraph of a graph, which is known to be NP-complete, in polynomial time. Although what we did does not imply the original problem to be NP-complete, it does shed some light on how to solve the problem: we will use the backtracking method to find the largest Brinkhuis triple.

We say a number i is compatible with a list of numbers $i_1,\ldots,i_n$ if any three words chosen from the corresponding words $w_i, w_{i_1},\ldots,w_{i_n}$ can form a quasi-special (special) Brinkhuis 3-triple.

Assuming all the numbers in the vertices are ordered increasingly, we try to construct the largest quasi-special (special) Brinkhuis triples recursively: We start with the pair of numbers, a_1 and a_2, who has the largest set of compatible numbers of all pairs of numbers in $\{1,\ldots,m\}$. After we have a list $a_1,\ldots,a_{n-1}$ such that every three numbers in the list can form a quasi-special (special) Brinkhuis 3-triple, we try to find a_n as the number such that a_n is compatible with $a_1,\ldots,a_{n-1}$, and $a_1,\ldots,a_n$ has the largest possible set of compatible numbers. If there is a tie, we choose the smallest possible number. Once we cannot add another number to the current list of $a_1,\ldots,a_n$, we have found a "locally optimal" Brinkhuis n-triple. We then backtrack to a_{n-1} and search for the next best choice of a_n. When all such choices are analyzed, we backtrack to a_{n-2}. We repeat the process until we backtrack to a_1 and a_2, when we try the pair of numbers who has the next largest set of compatible numbers. We will continue until all the possibilities are considered. Of course, we can always break out of the search if the size of the list of numbers found plus the number of compatible numbers available is less than the best known size of the triples at the time.

The complexity of searching the largest complete subgraph of n vertices is equivalent to searching the largest independent set of vertices of the complement of the graph, whose *average* rate of growth is subexponential, i.e., $O(n^{\log n})$. However, the exact amount of labor required for a specific kind of graphs can be very exponential. Theoretically, we can take advantage of the special structure of the graphs to increased the performance: if vertices $[1,2,3]$ and $[4,5,6]$ are connected, there is automatically a complete subgraph of 20 vertices, namely any combinations of three numbers from 1 to 6. But such an approach will use recursive programming, which would have required exponential space and thus is impractical. Unless we can find other methods to find the lower bound, using Brinkhuis triples cannot provide

must better results, even with more powerful (multi-processor) computers. Unfortunately, this is the best method known yet, if not the only one.

The Maple package and the results on optimal Brinkhuis triples are all available at http://www.math.temple.edu/∼xysun/ternarysf/ternary_square_free.htm.

Journal of Integer Sequences, Vol. 6 (2003), Article 03.3.3

Matrix Transformations of Integer Sequences

Clark Kimberling
Department of Mathematics
University of Evansville
1800 Lincoln Avenue
Evansville, IN 47722

Abstract: The integer sequences with first term 1 comprise a group $\mathcal{G}$ under convolution, namely, the Appell group, and the lower triangular infinite integer matrices with all diagonal entries 1 comprise a group $\mathbb{G}$ under matrix multiplication. If $A \in \mathcal{G}$ and $M \in \mathbb{G}$, then $MA \in \mathcal{G}$. The groups $\mathcal{G}$ and $\mathbb{G}$ and various subgroups are discussed. These include the group $\mathbb{G}^{(1)}$ of matrices whose columns are identical except for initial zeros, and also the group $\mathbb{G}^{(2)}$ of matrices in which the odd-numbered columns are identical except for initial zeros and the same is true for even-numbered columns. Conditions are determined for the product of two matrices in $\mathbb{G}^{(m)}$ to be in $\mathbb{G}^{(1)}$. Conditions are also determined for two matrices in $\mathbb{G}^{(2)}$ to commute.

Abstract: The integer sequences with first term 1 comprise a group $\mathcal{G}$ under convolution, namely, the Appell group, and the lower triangular infinite integer matrices with all diagonal entries 1 comprise a group $\mathbb{G}$ under matrix multiplication. If $A \in \mathcal{G}$ and $M \in \mathbb{G}$, then $MA \in \mathcal{G}$. The groups $\mathcal{G}$ and $\mathbb{G}$ and various subgroups are discussed. These include the group $\mathbb{G}^{(1)}$ of matrices whose columns are identical except for initial zeros, and also the group $\mathbb{G}^{(2)}$ of matrices in which the odd-numbered columns are identical except for initial zeros and the same is true for even-numbered columns. Conditions are determined for the product of two matrices in $\mathbb{G}^{(m)}$ to be in $\mathbb{G}^{(1)}$. Conditions are also determined for two matrices in $\mathbb{G}^{(2)}$ to commute.

1 Introduction

Let $\mathcal{G}$ be the set of integer sequences $(a_1, a_2, a_3, \ldots)$ for which $a_1 = 1$. The notations $A = (a_1, a_2, a_3, \ldots)$, $B = (b_1, b_2, b_3, \ldots)$, $C = (c_1, c_2, c_3, \ldots)$ will always refer to elements of $\mathcal{G}$. The finite sequence $(a_1, a_2, a_3, \ldots, a_n)$ will be denoted by A_n, and likewise for B_n and C_n. Let $\star$ denote convolution; i.e., if $C = A \star B$, then

$$c_n = \sum_{k=1}^{n} a_k b_{n-k+1},$$

which we shall sometimes write as $A_n \circledast B_n$, so that $A \star B$ is the sequence having $A_n \circledast B_n$ as nth term. Formally,

$$\sum_{k=1}^{\infty} c_k x^{k-1} = \left(\sum_{k=1}^{\infty} a_k x^{k-1} \right) \left(\sum_{k=1}^{\infty} b_k x^{k-1} \right).$$

In particular, if $c_1 = 1$ and $c_k = 0$ for $k \geq 2$, then the sequence B has generating function $1/(a_1 + a_2x + a_3x^2 + \cdots)$, and A and B are a pair of convolutory inverses.

Let $\mathcal{G}_n$ denote the group of finite sequences A_n under $\star$; the identity is $I_n = (1, 0, 0, \ldots, 0)$, and A_n^{-1} is the sequence B_n given inductively by $b_1 = 1$ and

$$b_n = -\sum_{k=1}^{n-1} a_{n-k+1} b_k. \tag{1}$$

for $n \geq 2$. The algebraic system $(\mathcal{G}, \star)$ is a commutative group known as the Appell subgroup of the Riordan group. Its elements, the Appell sequences, are special cases of the Sheffler sequences, which play a leading role in the umbral calculus [2, Chapter 4]; however, the umbral developments are not used in this paper. In $\mathcal{G}$, the identity and A^{-1} are the limits of I_n and A_n^{-1}. (Here, limits are of the combinatorial kind: suppose $j_1, j_2, j_3, \ldots$ is an unbounded nondecreasing sequence of positive integers and $\{a_{i,j}\}$ is a sequence of sequences such for each i,

$$(a_{k,1}, a_{k,2}, a_{k,3}, \ldots, a_{k,j_i}) = (a_{i,1}, a_{i,2}, a_{i,3}, \ldots, a_{i,j_i})$$

for every $k > i$. Then

$$\lim_{i \to \infty} (a_{i,1}, a_{i,2}, a_{i,3}, \ldots)$$

is defined as the sequence $(a_1, a_2, a_3, \ldots)$ such that for every n there exists i_0 such that if $i > i_0$, then

$$(a_1, a_2, a_3, \ldots, a_n) = (a_{i,1}, a_{i,2}, a_{i,3}, \ldots, a_{i,n}).)$$

The study of the group $(\mathcal{G}, \star)$, we shall soon see, is essentially that of a certain group of matrices. However, we shall consider first a more general group of matrices.

For any positive integer n, let $\mathbb{G}_n$ be the set of lower triangular $n \times n$ integer matrices with all diagonal entries 1, and let $\cdot$ denote matrix multiplication. Then $(\mathbb{G}_n, \cdot)$ is a noncommutative group. Now let $\mathbb{G}$ denote the set of lower triangular infinite integer matrices with all diagonal entries 1. In such a matrix, every column, excluding the zeros above the diagonal, is an element of $\mathcal{G}$, and $(\mathbb{G}, \cdot)$ is a noncommutative group. Properties of matrices in $\mathbb{G}$ arise via limits of those of matrices in $\mathbb{G}_n$. For example, if $M = (m_{ij}) \in \mathbb{G}$, then the matrix $M_n := (m_{ij})$, where $1 \leq i \leq n$ and $1 \leq j \leq n$, is an element of $\mathbb{G}_n$, and

$$M^{-1} = \lim_{n \to \infty} M_n^{-1}.$$

It is easy to check that if $A \in \mathcal{G}$ and $M \in \mathbb{G}$, then $M \cdot A \in \mathcal{G}$; here A is regarded as an infinite column vector.

Among subgroups of $\mathbb{G}$ is the Riordan group (in the case that the coefficients are all integers) introduced in [3]. Although the Riordan group will not be further discussed in this paper, the reader may wish to consult the references listed at A053121 (the Catalan triangle) in [4].

Suppose $T = (t_1, t_2, t_3, \ldots) \in \mathcal{G}$. Let $\mathbb{T}$ be the matrix in $\mathbb{G}$ whose ith row is

$$t_i, t_{i-1}, \ldots, t_1, 0, 0 \ldots,$$

so that the first column of $\mathbb{T}$ is T, and each subsequent column contains T as a subsequence. Let $\mathbb{G}^{(1)}$ be the set of all such matrices $\mathbb{T}$. If $\mathbb{T}$ and $\mathbb{U}$ in $\mathbb{G}^{(1)}$ have first columns T and U, respectively, then the first column of $\mathbb{T} \cdot \mathbb{U}$ is the sequence $T \star U$, and $\mathbb{T} \cdot \mathbb{U} \in \mathbb{G}^{(1)}$. Clearly, $(\mathbb{G}^{(1)}, \cdot)$ is isomorphic to $(\mathcal{G}, \star)$. Matrices in $\mathbb{G}^{(1)}$ will be called *sequential matrices.*

One more property of the group $\mathbb{G}$, with easy and omitted proof, will be useful: if $M = (m_{ij}) \in \mathbb{G}$ and $f(M) := ((-1)^{i+j} m_{ij})$, then

$$(f(M))^{-1} = f(M^{-1}). \tag{2}$$

2 The Appell group $(\mathcal{G}, \star)$

The first theorem in this section concerns the convolutory inverse of a linear recurrence sequence of order $m \geq 2$.

Theorem 1. *Suppose $m \geq 2$, and $a_1 = 1, a_2, \ldots, a_m$ are initial values of an mth order recurrence sequence given by*

$$a_n = u_1 a_{n-1} + u_2 a_{n-2} + \cdots + u_m a_{n-m} + r_{n-m} \tag{3}$$

for $n \geq m+1$, where $u_1, u_2, \ldots, u_m$ and $r_1, r_2, r_3, \ldots$ are integers and $u_m \neq 0$. Then the convolutory inverse, B, of A, is a sequence

$$(1, b_2, \ldots, b_m, b_{m+1}, b_{m+2}, \ldots)$$

for which the subsequence $(b_{m+2}, b_{m+3}, \ldots)$ satisfies

$$b_n = \sum_{k=1}^{m-1} b_{n-k} c_k - B_{n-m} \circledast R_{n-m},$$

where

$$c_k = -a_{k+1} + \sum_{j=1}^{k} u_j a_{k+1-j}$$

for $n \geq m+2$.

Proof: By (1), $b_1 = a_1 = 1$. Also, $b_2 = -a_2$, and

$$b_n = -a_n b_1 - a_{n-1} b_2 - \cdots - a_2 b_{n-1}$$

for $n \geq 3$. For the rest of this proof, assume that $n \geq m+2$, and for later convenience, let

$$s_n = -a_n b_1 - a_{n-1} b_2 - \cdots - a_{m+2} b_{n-m-1}.$$

For $n \geq m+2$ (but not generally for $n = m+1$), the recurrence (1) gives

$$\sum_{k=1}^{m} u_k b_{n-k} = - \sum_{j=1}^{n-m-1} b_j \sum_{k=1}^{m} u_k a_{n-k-j+1} - U,$$

where

$$U = \sum_{k=1}^{m-1} u_k \sum_{j=2}^{m-k+1} a_j b_{n-k-j+1}.$$

Then

$$\begin{aligned}
\sum_{k=1}^{m} u_k b_{n-k} &= -\sum_{j=1}^{n-m-1} b_j (a_{n+1-j} - r_{n+1-j-m}) - U \\
&= s_n + \sum_{j=1}^{n-m-1} b_j r_{n+1-j-m} - U \\
&= b_n + \sum_{j=2}^{m+1} a_j b_{n+1-j} + \sum_{j=1}^{n-m-1} b_j r_{n+1-j-m} - U,
\end{aligned}$$

so that

$$b_n = \sum_{k=1}^{m} u_k b_{n-k} - \sum_{j=2}^{m+1} a_j b_{n+1-j} - \sum_{j=1}^{n-m-1} b_j r_{n+1-j-m} + U. \tag{4}$$

Now put $n = m+1$ into (3) and substitute in (4) for a_{m+1}. The resulting coefficient of b_{n-m} is $-r_1$, and (4) simplifies to

$$\begin{aligned}
b_n &= \sum_{k=1}^{m-1} u_k b_{n-k} - \sum_{j=2}^{m} a_j b_{n+1-j} + \sum_{k=1}^{m-2} u_k \sum_{j=2}^{m-k} a_j b_{n-k-j+1} - \sum_{j=1}^{n-m} b_j r_{n+1-j-m} \\
&= \sum_{k=1}^{m-1} b_{n-k}(-a_{k+1} + \sum_{j=1}^{k} u_j a_{k+1-j}) - \sum_{j=1}^{n-m} b_j r_{n+1-j-m.} \qquad \blacksquare
\end{aligned}$$

Corollary 1. If the recurrence for A in (3) is homogeneous of order $m \geq 2$, then the recurrence for the sequence $(b_4, b_5, b_6, \ldots)$ is of order $m-1$. If $m = 2$, then the convolutory inverse of A is the sequence

$$(b_1, b_2, b_3, \ldots) = (1,\ -a_2,\ f,\ (u_1 - a_2)f,\ (u_1 - a_2)^2 f,\ (u_1 - a_2)^3 f, \ldots),$$

where $f = a_2^2 - a_3$.

Proof: Homogeneity of a means that $r_n = 0$ for $n \geq 1$, so that $b_n = \sum_{k=1}^{m-1} c_k b_{n-k}$ for $n \geq m+2$. $\blacksquare$

Example 1. The Fibonacci sequence, $A = (1, 1, 2, 3, 5, 8, \ldots)$, has inverse $(1, -1, -1, 0, 0, 0, 0, 0, \ldots)$.

Example 2. The Lucas sequence, $A = (1, 3, 4, 7, 11, 18, \ldots)$, has inverse, $(1, -3, 5, -10, 20, -40, 80, \ldots)$, recurrent with order 1 beginning at the third term.

Example 3. Let A be the 2nd-order nonhomogeneous sequence given by $a_1 = 1$, $a_2 = 1$, and $a_n = a_{n-1} + a_{n-2} + n - 2$ for $n \geq 3$. The inverse of A is the sequence $B = (1, -1, -2, -1, 1, 4, 6, 4, -4, -11, \ldots)$ given for $n \geq 4$ by

$$b_n = -B_{n-2} \circledast R_{n-2} = -(b_1, b_2, \cdots, b_{n-2}) \star (1, 2, 3, \ldots, n-2).$$

Example 4. Suppose that A and C are sequences in $\mathcal{G}$. Since $\mathcal{G}$ is a group, there exists B in $\mathcal{G}$ such that $A = B \star C$. For example, if A and C are the Fibonacci and Lucas sequences of Examples 1 and 2, then

$$B = A \star C^{-1} = (1, -2, 4, -8, 16, \ldots),$$

a 1st-order sequence.

Theorem 2. *Let $B = (1, b_2, b_3, \ldots)$ be the convolutory inverse of $A = (1, a_2, a_3, \ldots)$, and let $\widehat{A} = (1, -a_2, a_3, -a_4, a_5, -a_6, \ldots)$. Then the convolutory inverse of $\widehat{A}$ is the sequence $\widehat{B} = (1, -b_2, b_3, -b_4, b_5, -b_6, \ldots)$.*

Proof: Apply (2) to the subgroup $\mathbb{G}^{(1)}$ of sequential matrices. ■

Example 5. Let A be the sequence given by $a_n = \lfloor n\tau \rfloor$, where $\tau = (1 + \sqrt{5})/2$. Then

$$A = (1, 3, 4, 6, 8, 9, 11, 12, \ldots) \quad \text{and} \quad A^{-1} = (1, -3, 5, -9, 17, -30, 52, -90, \ldots).$$

Let A be the sequence given by $a_n = (-1)^{n-1}\lfloor n\tau \rfloor$. Then

$$A = (1, -3, 4, -6, 8, -9, 11, -12, \ldots) \quad \text{and} \quad A^{-1} = (1, 3, 5, 9, 17, 30, 52, 90, \ldots).$$

Example 6. Let A be the Catalan sequence, given by $a_n = \frac{1}{n}\begin{pmatrix} 2n-2 \\ n-1 \end{pmatrix}$. Then

$$\begin{aligned} A &= (1, 1, 2, 5, 14, 42, 132, 429, 1430, \ldots) \\ A^{-1} &= (1, -1, -1, -2, -5, -14, -42, -132, \ldots). \end{aligned}$$

Example 7. Let A be the sequence of central binomial coefficients, given by $a_n = \begin{pmatrix} 2n-2 \\ n-1 \end{pmatrix}$, Then

$$A = (1, 2, 6, 20, 70, 252, 924, \ldots) \quad \text{and} \quad A^{-1} = (1, -2, -2, -4, -10, -28, -84, -264, \ldots),$$

with obvious connections to the Catalan sequence.

Certain operations on sequences in $\mathcal{G}$ are easily expressed in terms of convolution. Two of these operations are given as follows. Suppose x is an integer, and $A = (1, a_2, a_3, \ldots)$ is a sequence in $\mathcal{G}$, with inverse $B = (1, b_2, b_3, \ldots)$. Then

$$(1,\ xa_2,\ xa_3,\ xa_{4,}\ldots) = (1,\ (1-x)b_2,\ (1-x)b_3,\ (1-x)b_4, \ldots) \star A$$

and

$$(1,\ x,\ a_2,\ a_3, \ldots) = (1,\ x + b_2,\ (x-1)b_2 + b_3,\ (x-1)b_3 + b_4, \ldots) \star A.$$

Stated in terms of power series

$$a(t) = 1 + a_2 t + a_3 t^2 + \cdots \quad \text{and} \quad 1/a(t) = b(t) = 1 + b_2 t + b_3 t^2 + \cdots,$$

the two operations correspond to the identities

$$\begin{aligned} xa(t) + 1 - x &= [(1-x)b(t) + x]a(t); \\ ta(t) + 1 + (x-1)t &= \{b(t) + [(x-1)b(t) + 1]t\}a(t). \end{aligned}$$

3 The group $(\mathbb{G}^{(m)}, \cdot)$

Recall that the set $\mathbb{G}$ consists of the lower triangular infinite integer matrices with all diagonal entries 1. Define $'$ on $\mathbb{G}$ as follows: if $A \in \mathbb{G}$, then A' is the matrix that remains when row 1 and column 1 of A are removed. Clearly $A' \in \mathbb{G}$. Define

$$A^{(0)} = A, \qquad A^{(n)} = (A^{(n-1)})'$$

for $n \geq 1$. Let

$$\mathbb{G}^{(m)} = \{A \in \mathbb{G} : A^{(m)} = A\}$$

for $m \geq 0$. Note that $(\mathbb{G}^{(1)}, \cdot)$ is the group of sequential matrices introduced in Section 1, and $\mathbb{G}^{(m)} \subset \mathbb{G}^{(d)}$ if and only if $d|m$.

Theorem 3. *$(G^{(m)}, \cdot)$ is a group for $m \geq 0$.*

Proof: $(\mathbb{G}^{(0)}, \cdot)$ is the group $(\mathbb{G}, \cdot)$. For $m \geq 1$, first note that $(AB)' = A'B'$, so that, inductively, $(AB)^{(q)} = A^{(q)}B^{(q)}$ for all $q \geq 1$. In particular, if A and B are in $\mathbb{G}^{(m)}$, then

$$(AB)^{(m)} = A^{(m)}B^{(m)} = AB,$$

so that $AB \in \mathbb{G}^{(m)}$. Moreover,

$$(A^{-1})^{(m)} = (A^{(m)})^{-1} = A^{-1},$$

so that $A^{-1} \in \mathbb{G}^{(m)}$. ■

4 The group $(\mathbb{G}^{(2)}, \cdot)$

Suppose that A, B, C, D are sequences in $\mathcal{G}$. Let $\langle A; B\rangle$ denote the matrix in $\mathbb{G}^{(2)}$ whose first column is $A = (a_1, a_2, \ldots)$ and whose second column is $(0, b_1, b_2, \ldots)$, where $a_1 = b_1 = 1$. We shall see that the product $\langle A; B\rangle \cdot \langle C; D\rangle$ is given by certain "mixed convolutions." Write $\langle A; B\rangle \cdot \langle C; D\rangle$ as $\langle U; V\rangle$. Then

$$u_n = \begin{cases} (a_1, b_2, a_3, \ldots, b_{n-1}, a_n) \star (c_1, c_2, \ldots, c_n), & \text{if } n \text{ is odd;} \\ (b_1, a_2, b_3, \ldots, b_{n-1}, a_n) \star (c_1, c_2, \ldots, c_n), & \text{if } n \text{ is even;} \end{cases}$$

$$v_n = \begin{cases} (b_1, a_2, b_3, \ldots, a_{n-1}, b_n) \star (d_1, d_2, \ldots, d_n), & \text{if } n \text{ is odd;} \\ (a_1, b_2, a_3, \ldots, a_{n-1}, b_n) \star (d_1, d_2, \ldots, d_n), & \text{if } n \text{ is even.} \end{cases}$$

In particular $\langle A; B\rangle \cdot \langle B; A\rangle$ is the sequential matrix of the sequence $A \star B$.

Recursive formulas for columns of $\langle A; B\rangle^{-1}$ can also be given: write $\langle A; B\rangle^{-1}$ as $\langle X; Y\rangle$, so that $\langle A; B\rangle \cdot \langle X; Y\rangle$ is the identity matrix. Each nondiagonal entry of $\langle A; B\rangle \cdot \langle X; Y\rangle$ is zero, so that, solving inductively for $x_1, x_2, x_3, \ldots$ and $y_1, y_2, y_3, \ldots$ gives

$$x_n = \begin{cases} -a_n - b_{n-1}x_2 - a_{n-2}x_3 - \cdots - b_2 x_{n-1}, & \text{if } n \text{ is odd;} \\ -a_n - b_{n-1}x_2 - a_{n-2}x_3 - \cdots - a_2 x_{n-1}, & \text{if } n \text{ is even;} \end{cases} \tag{5}$$

$$y_n = \begin{cases} -b_n - a_{n-1}y_2 - b_{n-2}y_3 - \cdots - a_2 y_{n-1}, & \text{if } n \text{ is odd;} \\ -b_n - a_{n-1}y_2 - b_{n-2}y_3 - \cdots - b_2 y_{n-1}, & \text{if } n \text{ is even.} \end{cases} \tag{6}$$

Example 8. Example 6 shows that the Catalan sequence satisfies the equation

$$(1, a_2, a_3, \ldots)^{-1} = (1, -1, -a_2, -a_3, \ldots),$$

which we abbreviate as $A^{-1} = (1, -A)$. It is natural to ask whether there are sequences A and B for which

$$\langle A; B\rangle^{-1} = \langle 1, -A; B\rangle. \tag{7}$$

This problem is solved as follows. Write the first and second columns of $\langle 1, -A; B\rangle$ as $(1, x_2, x_3, \ldots)$ and $(0, 1, y_2, y_3, \ldots)$, respectively. Equation (7) implies $x_n = -a_{n-1}$ and $y_n = b_n$ for $n \geq 2$. Thus, $b_2 = y_2$, but also, by (6), $y_2 = -b_2$, so that $b_2 = 0$. Inductively, (6) and (7) imply $b_n = 0$ for all $n \geq 3$, so that B is the convolutory identity sequence: $B = (1, 0, 0, 0, \ldots)$. Using this fact together with (5) gives

$$x_n = \begin{cases} -a_n - a_{n-2}x_3 - a_{n-4}x_5 - \cdots - a_2 x_{n-1}, & \text{if } n \text{ is even;} \\ -a_n - a_{n-2}x_3 - a_{n-4}x_5 - \cdots - a_3 x_{n-2}, & \text{if } n \text{ is odd;} \end{cases}$$

so that, substituting $x_k = -a_{k-1}$, we have a recurrence for A:

$$a_n = \begin{cases} a_{n-1} + a_{n-2}a_2 + a_{n-4}a_4 + \cdots + a_2 a_{n-2} & \text{if } n \text{ is even;} \\ a_{n-1} + a_{n-2}a_2 + a_{n-4}a_4 + \cdots + a_3 a_{n-3} & \text{if } n \text{ is odd;} \end{cases}$$

with intial values $a_1 = 1$, $a_2 = 1$. This sequence, listed as A047749 in [4], is given by

$$a_n = \begin{cases} \frac{1}{2m+1}\begin{pmatrix} 3m \\ m \end{pmatrix}, & \text{if } n = 2m; \\ \frac{1}{2m+1}\begin{pmatrix} 3m+1 \\ m+1 \end{pmatrix}, & \text{if } n = 2m+1. \end{cases}$$

Example 9. Let $a_n = 1$ and $b_n = F_n$ for $n \geq 1$, where F_n denotes the Fibonacci sequence in Example 1. Let C be the sequence given by $c_1 = 1$, $c_2 = -1$, $c_3 = 0$, $c_4 = 1$, and $c_n = 2^{\lfloor (n-5)/2 \rfloor}$ for $n \geq 5$. Let D be the sequence given by $d_1 = 1$, $d_2 = -1$, $d_3 = -1$, and $d_n = -c_{n+1}$ for $n \geq d_4$. Then $\langle A; B\rangle^{-1} = \langle C; D\rangle$.

Theorem 4. *If any three of four sequences A, B, C, D in G are given, then the fourth sequence is uniquely determined by the condition that $\langle A; B\rangle \cdot \langle C; D\rangle$ be a sequential matrix.*

Proof: The requirement that $\langle A; B\rangle \cdot \langle C; D\rangle$ be a sequential matrix is equivalent to an infinite system of equations, beginning with

$$\begin{aligned} d_1 &= 1 \\ b_2 + d_2 &= a_2 + c_2 \\ b_3 + a_2 d_2 + d_3 &= a_3 + b_2 c_2 + c_3. \end{aligned}$$

For $n \geq 3$, the system can be expressed as follows:

$$\begin{aligned} & b_n + a_{n-1} d_2 + b_{n-2} d_3 + \cdots + h_2 d_{n-1} + d_n \\ = \; & a_n + b_{n-1} c_2 + a_{n-2} c_3 + \cdots + h_2' c_{n-1} + c_n, \end{aligned} \tag{8}$$

where $h_2 = a_2$ if n is odd, $h_2 = b_2$ if n is even; and $h_2' = b_2$ if n is odd, $h_2' = a_2$ if n is even.

Equations (8) show that each of the four sequences is determined by the other three. ■

Example 10. By (8), D is determined by A, B, C in accord with the recurrence

$$\begin{aligned} d_n = \; & a_n + c_2 b_{n-1} + c_3 a_{n-2} + c_4 b_{n-3} + \cdots + c_{n-1} h_2' + c_n \\ & -b_n - d_2 a_{n-1} - d_3 b_{n-2} - d_4 a_{n-3} \cdots - d_{n-1} h_2. \end{aligned} \tag{9}$$

Suppose $a_n = b_n = c_{n-2} = 0$ for $n \geq 3$. Then by (9),

$$d_n = \begin{cases} -b_2 d_{n-1} - a_3 d_{n-2}, & \text{if } n \text{ is even;} \\ -a_2 d_{n-1} - b_3 d_{n-2}, & \text{if } n \text{ is odd;} \end{cases}$$

for $n \geq 4$, with $d_1 = 1$, $d_2 = a_2 - b_2$, $d_3 = a_3 - a_2 d_2 - b_3 d_1$. If $(a_1, a_2, a_3) = (1, -1, -1)$ and $(b_1, b_2, b_3) = (1, -2, -1)$ and $c_1 = 1$, then

$$D = (1, 1, 1, 3, 4, 11, 15, 41, 56, 153, \ldots),$$

which, except for the initial 1, is the sequence of denominators of the convergents to $\sqrt{3}$, indexed in [4] as A002530. In this example, $\langle A; B\rangle \cdot \langle C; D\rangle$ is the sequential matrix with first three terms $1, -1, -1$ and all others zero.

Theorem 5. *If A, B, C in G are given and $|a_2| = 1$, then there exists a unique sequence D in G such that $\langle A; B\rangle \cdot \langle C; D\rangle = \langle C; D\rangle \cdot \langle A; B\rangle$.*

Proof: Write $\langle A; B\rangle \cdot \langle C; D\rangle$ as (s_{ij}) and $\langle C; D\rangle \cdot \langle A; B\rangle$ as (t_{ij}). Equating $s_{n+1,1}$ and $t_{n+1,1}$ and solving for d_n give

$$d_n = \frac{1}{a_2}(u_n - v_n) \tag{10}$$

for $n \geq 3$, where

$$u_n = \begin{cases} c_2b_n + c_3a_{n-1} + c_4b_{n-2} + \cdots + c_na_2, & \text{if } n \text{ is odd;} \\ c_2b_n + c_3a_{n-1} + c_4b_{n-2} + \cdots + c_nb_2, & \text{if } n \text{ is even;} \end{cases}$$

$$v_n = \begin{cases} a_3c_{n-1} + a_4d_{n-2} + \cdots + a_nc_2, & \text{if } n \text{ is odd;} \\ a_3c_{n-1} + a_4d_{n-2} + \cdots + a_nd_2, & \text{if } n \text{ is even;} \end{cases}$$

with $d_1 = 1$, $d_2 = b_2c_2/a_2$. A sequence D is now determined by (10); we shall refer to the foregoing as part 1.

It is necessary to check that the equations $s_{n+1,2} = t_{n+1,2}$ implied by

$$\langle A; B\rangle \cdot \langle C; D\rangle = \langle C; D\rangle \cdot \langle A; B\rangle$$

do not impose requirements on the sequence D that are not implied by those already shown to determine D. In fact, the equations $s_{n+1,2} = t_{n+1,2}$ with initial value $d_1 = 1$ determine exactly the same sequence D. To see that this is so, consider the mapping $\langle A; B\rangle' = \langle B; A\rangle$. It is easy to prove the following lemma:

$$(\langle A; B\rangle \cdot \langle C; D\rangle)' = \langle B; A\rangle \cdot \langle D; C\rangle .$$

By part 1 applied to $\langle B; A\rangle \cdot \langle D; C\rangle$ and $\langle D; C\rangle \cdot \langle B; A\rangle$, the first column of $\langle B; A\rangle \cdot \langle D; C\rangle$ equals the first column of $\langle D; C\rangle \cdot \langle B; A\rangle$. Therefore, by the lemma, the second column of $\langle A; B\rangle \cdot \langle C; D\rangle$ equals the second column of $\langle C; D\rangle \cdot \langle A; B\rangle$, which is to say that the equations $s_{n+1,2} = t_{n+1,2}$ hold. ■

Example 11. Let $a_1 = 1$, $a_2 = 1$, and $a_n = 0$ for $n \geq 3$. Let B be the Fibonacci sequence. Let $C = (1, 1, 0, 1, 0, 0, \ldots)$, with $c_n = 0$ for $n \geq 5$. Then D is given by $d_1 = 1$, $d_2 = 1$, $d_3 = 2$, and $d_n = L_{n-1}$ for $n \geq 4$, where (L_n) is the Lucas sequence, as in Example 1. Writing $\langle A; B\rangle \cdot \langle C; D\rangle$ as $\langle U, V\rangle$, we have $\langle U, V\rangle = \langle C; D\rangle \cdot \langle A; B\rangle$, where $U = (1, 2, 1, 3, 4, 7, 11, 18, \ldots)$ and $V = (1, 2, 5, 9, 20, 32, 66, 105, 207, \ldots)$.

5 Generalization of Theorem 4

It is natural to ask what sort of generalization Theorem 4 has for $m \geq 3$. The notation $\langle A; B\rangle$ used for matrices in $\mathbb{G}^{(2)}$ is now generalized in the obvious manner to $\langle A_1, A_2, \ldots, A_m\rangle$ in $\mathbb{G}^{(m)}$, where A_i is a sequence $(a_{i1}, a_{i2}, \ldots)$ having $a_{i1} = 1$, for $i = 1, 2, \ldots, m$.

Theorem 4A. *Suppose $A_1, A_2, \ldots, A_m$ and B_i for some i satisfying $1 \leq i \leq m$ are given. Then sequences B_j for $j \neq i$ are uniquely determined by the condition that $\langle A_1, A_2, \ldots, A_m\rangle \cdot \langle B_1, B_2, \ldots, B_m\rangle$ be a sequential matrix. Conversely, suppose $B_1, B_2, \ldots, B_m$ and A_i for some i satisfying $1 \leq i \leq m$ are given. Then sequences A_j for $j \neq i$ are uniquely determined by the condition that $\langle A_1, A_2, \ldots, A_m\rangle \cdot \langle B_1, B_2, \ldots, B_m\rangle$ be a sequential matrix.*

Proof: Let $U = AB$. For given A, each column of B uniquely determines the corresponding column of U, and each column of U determines the corresponding column of B. Thus, under

the hypothesis that a particular column B_i of B is given, the equation $U = AB$ determines the corresponding column of U. Consequently, as U is a sequential matrix, every column of U is determined, and this implies that every column of B is determined.

For the converse, suppose B, together with just one column A_i of A, are given, and that the product $U = AB$ is sequential. As a first induction step,

$$a_{21}b_{11} + a_{22}b_{21} = a_{32}b_{22} + a_{33}b_{32} = \cdots \ . \tag{11}$$

As $a_{i+1,i}$ is given, equations (11) show that $a_{h+1,h}$ is determined for all $h \geq 1$. Assume for arbitrary $k \geq 1$ that $a_{h+j,h}$ is determined for all j satisfying $1 \leq j \leq k$, for all $h \geq 1$. As U is sequential,

$$\begin{aligned} & a_{k+1,1}b_{11} + a_{k+1,2}b_{21} + \cdots + a_{k+1,k+1}b_{k+1,1} \\ = \ & a_{k+2,2}b_{22} + a_{k+2,3}b_{32} + \cdots + a_{k+2,k+2}b_{k+2,2} \\ = \ & \cdots \ . \end{aligned} \tag{12}$$

As $a_{k+i,i}$ is given, equations (12) and the induction hypothesis show that $a_{k+h,h}$ is determined for all $h \geq 1$. Thus, by induction, A is determined. ■

Theorem 4A shows that Theorem 4 extends to $\mathbb{G}^{(m)}$. The method of proof of Theorem 4A clearly applies to $\mathbb{G}$, so that Theorem 4A extends to $\mathbb{G}$.

6 Transformations involving divisors

We return to the general group $(\mathbb{G}, \cdot)$ for a discussion of several specific matrix transformations involving divisors of integers. The first is given by the left summatory matrix,

$$T(n,k) = \begin{cases} 1, & \text{if } k|n; \\ 0, & \text{otherwise.} \end{cases}$$

The inverse of T is the left Möbius transformation matrix. The matrices T and T^{-1} are indexed as A077049 and A077050 in [4], where transformations by T and T^{-1} of selected sequences in $\mathcal{G}$ are referenced. In general, if A is a sequence written as an infinite column vector, then

$$T \cdot A = \{\sum_{k|n} a_k\} \qquad \text{and} \qquad T^{-1} \cdot A = \{\sum_{k|n} \mu(k)a_k\},$$

that is, the summatory sequence of A and the Möbius transform of A, respectively.

Next, define the *left summing matrix* $S = \{s(n,k)\}$ and the *left differencing matrix* $D = \{d(n,k)\}$ by

$$\begin{aligned} s(n,k) &= \begin{cases} 1, & \text{if } k \leq n; \\ 0, & \text{otherwise.} \end{cases} \\ d(n,k) &= \begin{cases} (-1)^{n+k}, & \text{if } k = n \text{ or } k = n-1; \\ 0, & \text{otherwise.} \end{cases} \end{aligned}$$

Note that $D = S^{-1}$.

Example 12. Suppose that a sequence $C = (1, c_2, c_3, \ldots)$ in $\mathcal{G}$ is transformed to a sequence $A = (1, a_2, a_3, \ldots)$ by the sums $a_n = \sum_{k=1}^{n} c_k \lfloor n/k \rfloor$. In order to solve this system of equations, let $U(n,k) = \lfloor n/k \rfloor$ for $k \geq 1$, $n \geq 1$. Then $U = S \cdot T$, so that $U^{-1} = T^{-1} \cdot D$, which means that

$$c_n = \sum_{d|n} \mu(d)(a_{n/d} - a_{n/d-1}),$$

where $a_0 := 0$. If $a_n = 1$ for every $n \geq 1$, then $c_n = \mu(n)$. If $a_n = n$, then C is the convolutory identity, $(1, 0, 0, 0, \ldots)$. If $a_n = \binom{n+1}{2}$, then $c_n = \varphi(n)$. If $a_n = \binom{n+2}{3}$, then C is the sequence indexed as A000741 in [4] and discussed in [1] in connection with compositions of integers with relatively prime summands.

Abstract. We define the derivative of an integer to be the map sending every prime to 1 and satisfying the Leibnitz rule. The aim of the article is to consider the basic properties of this map and to show how to generalize the notion to the case of rational and arbitrary real numbers. We make some conjectures and find some connections with Goldbach's Conjecture and the Twin Prime Conjecture. Finally, we solve the easiest associated differential equations and calculate the generating function.

1 A derivative of a natural number

Let n be a positive integer. We would like to define a derivative n' such that $(n, n') = 1$ if and only if n is square-free (as is the case for polynomials). It would be nice to preserve some natural properties, for example $(n^k)' = kn^{k-1}n'$. Because $1^2 = 1$ we should have $1' = 0$ and $n' = (1 + 1 \cdots + 1)' = 0$, if we want to preserve linearity. But if we ignore linearity and use the Leibnitz rule only, we will find that it is sufficient to define p' for primes p. Let us try to define n' by using two natural rules:

- $p' = 1$ for any prime p,

- $(ab)' = a'b + ab'$ for any $a, b \in \mathbf{N}$ (Leibnitz rule).

For instance,

$$6' = (2 \cdot 3)' = 2' \cdot 3 + 2 \cdot 3' = 1 \cdot 3 + 2 \cdot 1 = 5.$$

Here is a list of the first 18 positive integers and their first, second and third derivatives:

n	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
n'	0	1	1	4	1	5	1	12	6	7	1	16	1	9	8	32	1	21
n''	0	0	0	4	0	1	0	16	5	1	0	32	0	6	12	80	0	10
n'''	0	0	0	4	0	0	0	32	1	0	0	80	0	5	16	176	0	7

It looks quite unusual but first of all we need to check that our definition makes sense and is well-defined.

Theorem 1 *The derivative n' can be well-defined as follows: if $n = \prod_{i=1}^{k} p_i^{n_i}$ is a factorization in prime powers, then*

$$n' = n \sum_{i=1}^{k} \frac{n_i}{p_i}. \tag{1}$$

It is the only way to define n' that satisfies desired properties.

Proof. Because $1' = (1 \cdot 1)' = 1' \cdot 1 + 1 \cdot 1' = 2 \cdot 1'$, we have only one choice for $1'$: it should be zero. Induction and Leibnitz rule show that if the derivative is well-defined, it is uniquely determined. It remains to check that the equation (1) is consistent with our conditions. It is evident for primes and clear that (1) can be used even when some n_i are equal to zero. Let $a = \prod_{i=1}^{k} p_i^{a_i}$ and $b = \prod_{i=1}^{k} p_i^{b_i}$. Then according to (1) the Leibnitz rule looks as

$$ab \sum_{i=1}^{k} \frac{a_i + b_i}{p_i} = \left(a \sum_{i=1}^{k} \frac{a_i}{p_i} \right) b + a \left(b \sum_{i=1}^{k} \frac{b_i}{p_i} \right)$$

and the consistency is clear. ■

For example

$$(60)' = (2^2 \cdot 3 \cdot 5)' = 60 \cdot \left(\frac{2}{2} + \frac{1}{3} + \frac{1}{5} \right) = 60 + 20 + 12 = 92.$$

We can extend our definition to $0' = 0$, and it is easy to check that this does not contradict the Leibnitz rule.

Note that linearity does not hold in general; for many a, b we have $(a + b)' \neq a' + b'$. Furthermore $(ab)'' \neq a'' + 2a'b' + b''$ because we need linearity to prove this. It would be interesting to describe all the pairs (a, b) that solve the differential equation $(a+b)' = a'+b'$. We can find one of the solutions, $(4, 8)$ in our table above. This solution can be obtained from the solution $(1, 2)$ by using the following result.

Theorem 2 *If $(a+b)' = a' + b'$, then for any natural k, we have*

$$(ka+kb)' = (ka)' + (kb)'.$$

The same holds for the inequalities

$$(a+b)' \geq a' + b' \Rightarrow (ka+kb)' \geq (ka)' + (kb)',$$

$$(a+b)' \leq a' + b' \Rightarrow (ka+kb)' \leq (ka)' + (kb)'.$$

Moreover, all these can be extended for linear combinations, for example:

$$(\sum \gamma_i a_i)' = \sum \gamma_i (a_i)' \Rightarrow (k \sum \gamma_i a_i)' = \sum \gamma_i (ka_i)'.$$

Proof. The proof is the same for all the cases, so it is sufficient to consider only one of them, for example the case $\geq$ with two summands:

$$(ka+kb)' = (k(a+b))' = k'(a+b) + k(a+b)' =$$

$$k'a + k'b + k(a+b)' \geq k'a + k'b + ka' + kb' = (ka)' + (kb)'.$$

■

Corollary 1

$$(3k)' = k' + (2k)'; (2k)' \geq 2k'; (5k)' \leq (2k)' + (3k)'; (5k)' = (2k)' + 3(k)'.$$

Proof.

$$3' = 1' + 2'; 2' \geq 1' + 1'; 5' \leq 2' + 3'; 5' = 2' + 3 \cdot 1'.$$

■

Here is the list of all (a, b) with $a < b \leq 100, \gcd(a, b) = 1$, for which $(a+b)' = a' + b'$:

$$(1,2), (4,35), (4,91), (8,85), (11,14), (18,67), (26,29),$$

$$(27,55), (35,81), (38,47), (38,83), (50,79), (62,83), (95,99).$$

A similar result is

Theorem 3 *For any natural $k > 1$,*

$$n' \geq n \Rightarrow (kn)' > kn.$$

Proof.

$$(kn)' = k'n + kn' > kn' \geq kn.$$

■

The following theorem shows that every $n > 4$ that is divisible by 4 satisfies the condition $n' > n$.

Theorem 4 *If $n = p^p \cdot m$ for some prime p and natural $m > 1$, then $n' = p^p(m + m')$ and $\lim_{k\to\infty} n^{(k)} = \infty$.*

Proof. According to the Leibnitz rule and (1), $n' = (p^p)' \cdot m + p^p \cdot m' = p^p(m + m') > n$ and by induction $n^{(k)} \geq n + k$. ■

The situation changes when the exponent of p is less than p.

Theorem 5 *Let p^k be the highest power of prime p that divides the natural number n. If $0 < k < p$, then p^{k-1} is the highest power of p that divides n'. In particular, all the numbers $n, n', n'', \ldots, n^{(k)}$ are distinct.*

Proof. Let $n = p^k m$. Then $n' = kp^{k-1}m + p^k m' = p^{k-1}(km + pm')$, and the expression inside parentheses is not divisible by p. ■

Corollary 2 *A positive integer n is square-free if and only if $(n, n') = 1$.*

Proof. If $p^2|n$, then $p|n'$ and $(n, n') > 1$. On the other hand, if $p|n$ and $p|n'$ then $p^2|n$. ■

2 The equation $n' = n$

Let us solve some differential equations (using our definition of derivative) in positive integers.

Theorem 6 *The equation $n' = n$ holds if and only $n = p^p$, where p is any prime number. In particular, it has infinitely many solutions in natural numbers.*

Proof. If prime p divides n, then according to Theorem 5, at least p^p should divide n or else $n' \neq n$. But Theorem 4 implies that in this case $n = p^p$, which according to (1) is evidently equal to n'. ■

Thus, considering the map $n \longrightarrow n'$ as a dynamical system, we have a quite interesting object. Namely, we have infinitely many fixed points, 0 is a natural attractor, because all the primes after two differentiations become zero. Now it is time to formulate the first open problem.

Conjecture 1 *There exist infinitely many composite numbers n such that $n^{(k)} = 0$ for sufficiently large natural k.*

As we will see later, the Twin Prime Conjecture would fail if this conjecture is false. Preliminary numerical experiments show that for non-fixed points either the derivatives $n^{(k)}$ tend to infinity or become zero; however, we do not know how to prove this.

Conjecture 2 *Exactly one of the following could happen: either $n^{(k)} = 0$ for sufficiently large k, or $\lim_{k\to\infty} n^{(k)} = \infty$, or $n = p^p$ for some prime p.*

According to Theorem 4, it is sufficient to prove that, for some k, the derivative $n^{(k)}$ is divisible by p^p (for example by 4). In particularly we do not expect periodic point except fixed points p^p.

Conjecture 3 *The differential equation $n^{(k)} = n$ has only trivial solutions p^p for primes p.*

Theorem 5 gives some restrictions for possible nontrivial periods: if p^k divides n the period must be at least $k + 1$.

Conjecture 3 is not trivial even in special cases. Suppose, for example, that n has period 2, i.e. $m = n' \neq n$ and $m' = n$. According to Theorem 4 and Theorem 5, both n and m should be the product of distinct primes: $n = \prod_{i=1}^{k} p_i$, $m = \prod_{j=1}^{l} q_j$, where all primes p_i are distinct from all q_j. Therefore, our conjecture in this case is equivalent to the following:

Conjecture 4 *For any positive integers k, l, the equation*

$$\left(\sum_{i=1}^{k} \frac{1}{p_i}\right)\left(\sum_{j=1}^{l} \frac{1}{q_j}\right) = 1$$

has no solutions in distinct primes.

3 The equation $n' = a$

We start with two easy equations.

Theorem 7 *The differential equation $n' = 0$ has only one positive integer solution $n = 1$.*

Proof. Follows immediately from (1). ■

Theorem 8 *The differential equation $n' = 1$ in natural numbers has only primes as solutions.*

Proof. If the number is composite then according to Leibnitz rule and the previous theorem, the derivative can be written as the sum of two positive integers and is greater than 1. ■

All other equations $n' = a$ have only finitely many solutions, if any.

Theorem 9 *([1]) For any positive integer n*

$$n' \leq \frac{n \log_2 n}{2}. \tag{2}$$

If n is not a prime, then

$$n' \geq 2\sqrt{n}. \tag{3}$$

More generally, if n is a product of k factors larger than 1, then

$$n' \geq k n^{\frac{k-1}{k}}. \tag{4}$$

Proof. If $n = \prod_{i=1}^{k} p_i^{n_i}$, then

$$n \geq \prod_{i=1}^{k} 2^{n_i} \Rightarrow \log_2 n \geq \sum_{i=1}^{k} n_i.$$

According to (1) we now have

$$n' = n \sum_{i=1}^{k} \frac{n_i}{p_i} \leq \frac{n \sum_{i=1}^{k} n_i}{2} \leq \frac{n \log_2 n}{2}.$$

If $n = n_1 n_2 n_3 \cdots n_k$ then, according to the Leibnitz rule,

$$n' = n_1' n_2 n_3 \cdots n_k + n_1 n_2' n_3 \cdots n_k + n_1 n_2 n_3' \cdots n_k + \ldots + n_1 n_2 n_3 \cdots n_k' \geq$$

$$n_2 n_3 n_4 \cdots n_k + n_1 n_3 n_4 \cdots n_k + n_1 n_2 n_4 \cdots n_k + \ldots + n_1 n_2 \cdots n_{k-1} =$$

$$n\left(\frac{1}{n_1} + \frac{1}{n_2} + \ldots + \frac{1}{n_k}\right) \geq n \cdot k \left(\frac{1}{n_1} \cdot \frac{1}{n_2} \cdots \frac{1}{n_k}\right)^{\frac{1}{k}} = k \cdot n \cdot n^{\frac{-1}{k}} = k \cdot n^{\frac{k-1}{k}}.$$

Here we have replaced the arithmetic mean by the geometric mean. ■

Note that bounds (2) and (4) are exact for $n = 2^k$.

Corollary 3 *If the differential equation $n' = a$ has any solution in natural numbers, then it has only finitely many solutions if $a > 1$.*

Proof. The number n cannot be a prime. According to (3) the solutions must be no greater than $\frac{a^2}{4}$. ■

What about the existence of solutions? We start with the even numbers.

Conjecture 5 *The differential equation $n' = 2b$ has a positive integer solution for any natural number $b > 1$.*

A motivation for this is the famous

Conjecture 6 (Goldbach Conjecture) *Every even number larger than 3 is a sum of two primes.*

So, if $2b = p + q$, then $n = pq$ is a solution that we need. Inequality (3) helps us easy to prove that the equation $n' = 2$ has no solutions. What about odd numbers larger than 1? It is easy to check with the help of (3) that the equation $n' = 3$ has no solutions. For $a = 5$ we have one solution and more general have a theorem:

Theorem 10 *Let p be a prime and $a = p + 2$. Then $2p$ is a solution for the equation $n' = a$.*

Proof. $(2p)' = 2'p + 2p' = p + 2$. ■

Some other primes also can be obtained as a derivative of a natural number (e.g. 7), but it is more interesting which of numbers cannot. Here is a list of all $a \leq 1000$ for which the equation $n' = a$ has no solutions (obtained using Maple and (3)):

$$2, 3, 11, 17, 23, 29, 35, 37, 47, 53, 57, 65, 67, 79, 83, 89, 93, 97, 107, 117, 125, 127,$$

$$137, 145, 149, 157, 163, 173, 177, 179, 189, 197, 205, 207, 209, 217, 219, 223, 233,$$

$$237, 245, 257, 261, 277, 289, 303, 305, 307, 317, 323, 325, 337, 345, 353, 367, 373,$$

$$377, 379, 387, 389, 393, 397, 409, 413, 415, 427, 429, 443, 449, 453, 457, 473, 477,$$

$$485, 497, 499, 509, 513, 515, 517, 529, 531, 533, 537, 547, 553, 561, 569, 577, 593,$$

$$597, 605, 613, 625, 629, 639, 657, 659, 665, 673, 677, 681, 683, 697, 699, 709, 713,$$

$$715, 733, 747, 749, 757, 765, 769, 777, 781, 783, 785, 787, 793, 797, 805, 809, 817,$$

$$819, 827, 833, 835, 845, 847, 849, 853, 857, 869, 873, 877, 881, 891, 895, 897, 907,$$

$$917, 925, 933, 937, 947, 953, 963, 965, 967, 981, 989, 997.$$

Note that a large portion of them (69 from 153) are primes, one of them ($529 = 23^2$) is a square, and some of them (e.g. $765 = 3^2 \cdot 5 \cdot 17$) have at least 4 prime factors. In general it is interesting to investigate the behavior of the "integrating" function $I(a)$ which calculates for every a the set of solutions of the equation $n' = a$ and its weaker variant $i(a)$ that calculates the number of such solutions. As we have seen above $I(0) = \{0, 1\}$, $I(1)$ consist of all primes and $i(2) = i(3) = i(11) = \cdots = i(997) = 0$. Here is a list of the those numbers $a \leq 100$ that have more than one "integral" (i.e. $i(a) \geq 2$). For example 10 has two "integrals" (namely $I(10) = \{21, 25\}$) and 100 has six ($I(100) = \{291, 979, 1411, 2059, 2419, 2491\}$).

[96, 8], [98, 3], [100, 6].
```

Note that only three of them are primes. To complete the picture it remains to list the set of those $a <= 100$ for which $i(a) = 1$.

$$4, 5, 6, 7, 8, 9, 13, 15, 19, 25, 27, 33, 41,$$

$$43, 49, 51, 59, 63, 69, 73, 77, 85, 95, 99.$$

Theorem 11 *The function $i(n)$ is unbounded for $n > 1$.*

Proof. Suppose that $i(n) < C$ for all $n > 1$ for some constant C. Then

$$\sum_{k=2}^{2n} i(k) < 2Cn$$

for any n. But for any two primes p, q the product pq belongs to $I(p+q)$ thus

$$\sum_{k=2}^{2n} i(k) > \sum_{p \le q \le n}{}' 1 = \frac{\pi(n)(\pi(n)+1)}{2} > \frac{\pi(n)^2}{2},$$

where $\sum'$ means that the sum runs over the primes, and $\pi(n)$ is the number of primes not exceeding n. This leads to the inequality

$$2Cn > \frac{\pi(n)^2}{2} \Rightarrow \pi(n) < 2\sqrt{Cn},$$

which contradicts the known asymptotic behavior $\pi(n) \approx \frac{n}{\ln n}$. ■

It would be interesting to prove a stronger result.

Conjecture 7 *For any nonnegative m there exists infinitely many a such that $i(a) = m$.*

Another related conjecture is the following:

Conjecture 8 *There exists an infinite sequence a_n of different natural numbers such that $a_1 = 1, (a_n)' = a_{n-1}$ for $n = 2, 3 \ldots$*

Here is an example of possible beginning of such a sequence:

$$1 \leftarrow 7 \leftarrow 10 \leftarrow 25 \leftarrow 46 \leftarrow 129 \leftarrow 170 \leftarrow 501 \leftarrow 414 \leftarrow 2045.$$

The following table shows the maximum of $i(n)$ depending of the number m of (not necessary different) prime factors in the factorization of n for $n \le 1000$.

m	1	2	3	4	5	6	7	8	9
$i(n)$	8	22	35	46	52	52	40	47	32

The next more detailed picture shows the distribution of $i(n)$ depending of the number m for $i(n) < 33$. Note that maximum possible $i(n)$ is equal 52, so we have only part of a possible table. We leave to the reader the pleasure of making some natural conjectures.

$i(n)\backslash m$	1	2	3	4	5	6	7	8	9
0	69	49	28	6	1	0	0	0	0
1	46	89	35	8	3	1	0	0	0
2	25	44	18	7	1	0	0	0	0
3	13	16	17	7	0	0	0	0	0
4	9	12	8	5	2	0	1	0	0
5	2	6	3	4	0	1	0	0	0
6	1	7	8	1	2	0	0	0	0
7	1	10	4	3	2	1	0	0	0
8	2	3	8	3	2	2	0	1	0

32	0	0	0	6	1	1	1	0	1

4 The equation $n'' = 1$

The main conjecture for the second-order equations is the following:

Conjecture 9 *The differential equation $n'' = 1$ has infinitely many solutions in natural numbers.*

Theorem 10 shows that $2p$ is a solution if $p, p+2$ are primes. So the following famous conjecture would be sufficient to prove.

Conjecture 10 *(**prime twins**) There exists infinitely many pairs $p, p+2$ of prime numbers.*

The following problem is another alternative which would be sufficient:

Conjecture 11 *(**prime triples**) There exists infinitely many triples p, q, r of prime numbers such that $P = pq + pr + qr$ is a prime.*

Such a triple gives a solution $n = pqr$ to our equation, because $n' = P$. In reality all the solutions can be described as follows.

Theorem 12 *A number n is a solution of the differential equation $n'' = 1$ if and only if the three following conditions are valid:*

1. *The number n is a product of different primes: $n = \prod_{i=1}^{k} p_i$.*
2. *$\sum_{i=1}^{k} 1/p_i = \frac{p}{n}$, where p is a prime.*
3. *If k is even, then the smallest prime of p_i should be equal to 2.*

Proof. If $n = p^2 m$ for some prime p then $n' = p(2m + pm')$ is not prime and according to Theorem 8 the number n cannot be a solution. So, it is a product of different primes. Then the second condition means that n' is a prime and by Theorem 8 it is necessary and sufficient to be a solution. As to the number k of factors it cannot be even if all primes p_i are odd, because n' in this case is (as the sum of k odd numbers) even and larger than two. ■

5 Derivative for integers

It is time to extend our definition to integers.

Theorem 13 *A derivative is uniquely defined over the integers by the rule*

$$(-x)' = -x'.$$

Proof. Because $(-1)^2 = 1$ we should have (according to the Leibnitz rule) $2(-1)' = 0$ and $(-1)' = 0$ is the only choice. After that $(-x)' = ((-1) \cdot x)' = 0 \cdot x' + (-1) \cdot x' = -x'$ is the only choice for negative $-x$ and as a result is true for positive integers also. It remains to check that the Leibnitz rule is still valid. It is sufficient to check that it is valid for $-a$ and b if it was valid for a and b. It follows directly:

$$((-a) \cdot b)' = -(a \cdot b)' = -(a' \cdot b + a \cdot b') = -a' \cdot b + (-a) \cdot b' = (-a)' \cdot b + (-a) \cdot b'.$$

■

6 Derivative for rational numbers

The next step is to differentiate a rational number. We start from the positive rationals. The shortest way is to use (1). Namely, if $x = \prod_{i=1}^{k} p_i^{x_i}$ is a a factorization of a rational number x in prime powers, (where some x_i may be negative) then we put

$$x' = x \sum_{i=1}^{k} \frac{x_i}{p_i} \tag{5}$$

and the same proof as in Theorem 1 shows that this definition is still consistent with the Leibnitz rule.

Here is a table of derivatives of i/j for small i, j.

i/j	1	2	3	4	5	6	7	8	9	10
1	0	$\frac{-1}{4}$	$\frac{-1}{9}$	$\frac{-1}{4}$	$\frac{-1}{25}$	$\frac{-5}{36}$	$\frac{-1}{49}$	$\frac{-3}{16}$	$\frac{-2}{27}$	$\frac{-7}{100}$
2	1	0	$\frac{1}{9}$	$\frac{-1}{4}$	$\frac{3}{25}$	$\frac{-1}{9}$	$\frac{5}{49}$	$\frac{-1}{4}$	$\frac{-1}{27}$	$\frac{-1}{25}$
3	1	$\frac{-1}{4}$	0	$\frac{-1}{2}$	$\frac{2}{25}$	$\frac{-1}{4}$	$\frac{4}{49}$	$\frac{-7}{16}$	$\frac{-1}{9}$	$\frac{-11}{100}$
4	4	1	$\frac{8}{9}$	0	$\frac{16}{25}$	$\frac{1}{9}$	$\frac{24}{49}$	$\frac{-1}{4}$	$\frac{4}{27}$	$\frac{3}{25}$
5	1	$\frac{-3}{4}$	$\frac{-2}{9}$	-1	0	$\frac{-19}{36}$	$\frac{2}{49}$	$\frac{-13}{16}$	$\frac{-7}{27}$	$\frac{-1}{4}$
6	5	1	1	$\frac{-1}{4}$	$\frac{19}{25}$	0	$\frac{29}{49}$	$\frac{-1}{2}$	$\frac{1}{9}$	$\frac{2}{25}$
7	1	$\frac{-5}{4}$	$\frac{-4}{9}$	$\frac{-3}{2}$	$\frac{-2}{25}$	$\frac{-29}{36}$	0	$\frac{-19}{16}$	$\frac{-11}{27}$	$\frac{-39}{100}$
8	12	4	$\frac{28}{9}$	1	$\frac{52}{25}$	$\frac{8}{9}$	$\frac{76}{49}$	0	$\frac{20}{27}$	$\frac{16}{25}$
9	6	$\frac{3}{4}$	1	$\frac{-3}{4}$	$\frac{21}{25}$	$\frac{-1}{4}$	$\frac{33}{49}$	$\frac{-15}{16}$	0	$\frac{-3}{100}$
10	7	1	$\frac{11}{9}$	$\frac{-3}{4}$	1	$\frac{-2}{9}$	$\frac{39}{49}$	-1	$\frac{1}{27}$	0

A natural property is the following:

Theorem 14 *For any two rationals a, b we have*

$$\left(\frac{a}{b}\right)' = \frac{a'b - ab'}{b^2}.$$

A derivative can be well defined for rational numbers using this formula and this is the only way to define a derivative over rationals that preserves the Leibnitz rule.

Proof. If $a = \prod_{i=1}^{k} p_i^{a_i}, b = \prod_{i=1}^{k} p_i^{a_i}$ then we have

$$\left(\frac{a}{b}\right)' = (\prod_{i=1}^{k} p_i^{a_i - b_i})' = (\prod_{i=1}^{k} p_i^{a_i - b_i}) \sum_{i=1}^{k} \frac{a_i - b_i}{p_i} =$$

$$\left(\frac{a}{b}\right) \sum_{i=1}^{k} \frac{a_i}{p_i} - \left(\frac{ab}{b^2}\right) \sum_{i=1}^{k} \frac{b_i}{p_i} = \frac{a'}{b} - \frac{ab'}{b^2} = \frac{a'b - ab'}{b^2}.$$

Let us check uniqueness. If n is an integer then $n \cdot \frac{1}{n} = 1$ and the Leibnitz rule demands

$$n' \cdot \frac{1}{n} + n \left(\frac{1}{n}\right)' = 0 \Rightarrow \left(\frac{1}{n}\right)' = -\frac{n'}{n^2}.$$

After that

$$\left(\frac{a}{b}\right)' = \left(a \cdot \frac{1}{b}\right)' = a' \cdot \frac{1}{b} + a \cdot \left(\frac{1}{b}\right)' = \frac{a'}{b} - a \cdot \left(\frac{b'}{b^2}\right) = \frac{a'b - ab'}{b^2}$$

is the only choice that satisfies the Leibnitz rule. This proves uniqueness. To prove that such a definition is well-defined, it is sufficient to see that

$$\left(\frac{ac}{bc}\right)' = \frac{(ac)'(bc) - (ac)(bc)'}{(bc)^2} = \frac{(a'c + ac')(bc) - (ac)(b'c + bc')}{b^2c^2} =$$

$$\frac{(a'bc^2 + abc'c) - (ab'c^2 + abcc')}{b^2c^2} = \frac{a'b - ab'}{b^2}$$

has the same value. ■

For negative rationals we can proceed as above and put $(-x)' = -x'$.

7 Rational solutions of the equation $x' = a$.

Unexpectedly the equation $x' = 0$ has nontrivial rational solutions, for instance $x = 4/27$. We can describe all of them.

Theorem 15 *Let k be some natural number, $\{p_i, i = 1, \dots k\}$ be a set of different prime numbers and $\{\alpha_i, i = 1, \dots k\}$ be a set of integers such that $\sum_{i=1}^{k} \alpha_i = 0$. Then*

$$x = \pm \prod_{i=1}^{k} p_i^{\alpha_i p_i}$$

are solutions of the differential equation $x' = 0$ and any other nonzero solution can be obtained in this manner.

Proof. Because $(-x)' = -x'$ it is sufficient to consider positive solutions only. Let $x = \prod_{i=1}^{k} p_i^{a_i}$ Then from (5)

$$\sum_{i=1}^{k} \frac{a_i}{p_i} = 0 \Rightarrow \sum_{i=1}^{k} a_i \cdot Q_i = 0,$$

where $Q_i = \left(\prod_{j=1}^{k} p_j\right)/p_i$ is not divisible by p_i. Thus a_i should be divisible by p_i and $\alpha_i = \frac{a_i}{p_i}$. ■

Other equations are more difficult.

Conjecture 12 *The equation $x' = 1$ has only primes as positive rational solutions.*

Note that there exists a negative solution, namely $x = -\frac{5}{4}$. One possible solution of this equation would be $x = \frac{n}{p^p}$ for some natural n and prime p. Because $x' = \frac{n'-n}{p^p}$ in this case we can reformulate the conjecture as

Conjecture 13 *Let p be a prime. The equation $n' = n + p^p$ has no natural solutions except $n = qp^p$, where q is a prime.*

Note, that according to Theorem 5 if a solution n is divisible by p it should be divisible by p^p. Therefore $n = mp^p$ and $p^p(m' + m) = p^p(m + 1)$ by Theorem 4 and m should be a prime. Thus it is sufficient to prove that any solution is divisible by p.

We do not expect that it is possible to integrate every rational number, though we do not know a counterexample.

Conjecture 14 *There exists a such that the equation $x' = a$ has no rational solutions.*

The first natural candidates do not verify the conjecture:

$$(-\frac{21}{16})' = 2; (-\frac{13}{4})' = 3; (-\frac{22}{27})' = \frac{1}{3}.$$

8 Logarithmic derivative

One thing that is still absent in our picture is the analogue of the logarithm – the primitive of $\frac{1}{n}$. Because our derivative is not linear we cannot expect that the logarithm of the product is equal to the sum of logarithms. Instead this is true for its derivative. So let us define a logarithmic derivative $\mathrm{ld}(x)$ as follows. If $x = \prod_{i=1}^{k} p_i^{x_i}$ for different primes p_i and some integers x_i, then

$$\mathrm{ld}(x) = \sum_{i=1}^{k} \frac{x_i}{p_i},\ \mathrm{ld}(-x) = \mathrm{ld}(x),\ \mathrm{ld}(0) = \infty.$$

In other words

$$\mathrm{ld}(x) = \frac{x'}{x}.$$

Theorem 16 *For any rational numbers*

$$ld(xy) = ld(x) + ld(y).$$

Proof.

$$\mathrm{ld}(xy) = \frac{(xy)'}{xy} = \frac{x'y + xy'}{xy} = \frac{x'}{x} + \frac{y'}{y} = \mathrm{ld}(x) + \mathrm{ld}(y).$$

■

It is useful to divide every integer number into large and small parts. Let $\mathrm{sign}(x)x = |x| = \prod_{i=1}^{k} p_i^{x_i}$ and $x_i = a_i p_i + r_i$, where $0 \leq r_i < p_i$. We define

$$P(x) = \mathrm{sign}(x) \prod_{i=1}^{k} p_i^{a_i p_i}, R(x) = \prod_{i=1}^{k} p_i^{r_i}, A(x) = \sum_{i=1}^{k} a_i.$$

Theorem 17 *The following properties hold*

- $ld(x) = A(x) + ld(R(x))$.
- $x' = A(x)x + P(x)(R(x))' = x(A(x) + ld(R(x)))$.
- *If x is a nonzero integer, then*

$$x|x' \Leftrightarrow ld(x) \in \mathbf{Z} \Leftrightarrow R(x) = 1.$$

- *if $\left(\frac{a}{b}\right)'$ is an integer, and $\gcd(a, b) = 1$ then $R(b) = 1$.*

Proof. First we have

$$\mathrm{ld}(x) = \mathrm{ld}(P(x)R(x)) = \mathrm{ld}(P(x)) + \mathrm{ld}(R(x)) = A(x) + \mathrm{ld}(R(x)).$$

Using this we get

$$x' = x\mathrm{ld}(x) = x(A(x) + \mathrm{ld}(R(x))) = xA(x) + x\mathrm{ld}(R(x)) =$$

$$xA(x) + P(x)R(x)\mathrm{ld}(R(x)) = A(x)x + P(x)(R(x))'.$$

If $R(x) \neq 1$ then the sum

$$\mathrm{ld}(R(x)) = \sum_{i=1}^{k} \frac{r_i}{p_i}$$

cannot be an integer. Otherwise

$$\mathrm{ld}(R(x)) \prod_{i=1}^{k} p_i = \sum_{i=1}^{k} r_i Q_i,$$

and if $0 < r_j < p_j$ then an integer on the left hand side is divisible by p_j, but on the right hand side is not because $Q_j = \frac{\prod_{i=1}^{k} p_i}{p_j}$ and all primes p_i are different. The last statement follows from Theorem 14. ■

Now we are able to solve the equation $x' = \alpha x$ with rational α in the rationals. We have already solved this equation in the case $\alpha = 0$, so let $\alpha \neq 0$.

Theorem 18 *Let $\alpha = \frac{a}{b}$ be a rational number with $\gcd(a,b) = 1, b > 0$. Then*

- *The equation*
$$x' = \alpha x \tag{6}$$
has nonzero rational solutions if and only if b is a product of different primes or $b = 1$.

- *If x_0 is a nonzero particular solution (6) and y is any rational solution of the equation $y' = 0$ then $x = x_0 y$ is also a solution of (6) and any solution of (6) can be obtained in this manner.*

- *To obtain a particular solution of the equation (6) it is sufficient to decompose α into the elementary fractions:*
$$\alpha = \frac{a}{b} = \lfloor \alpha \rfloor + \sum_{i=1}^{k} \frac{c_i}{p_i},$$
where $b = \prod_{i=1}^{k} p_i, 1 \leq |c_i| < p_i$. Then
$$x_0 = 4^{\lfloor \alpha \rfloor} \prod_{i=1}^{k} p_i^{c_i}$$
is a particular solution. (Of course the number 4 can be replaced by p^p for any prime p).

Proof. The equation (6) is equivalent to the equation

$$\mathrm{ld}(x) = \alpha \Leftrightarrow A(x) + \mathrm{ld}(R(x)) = \alpha = \frac{a}{b}.$$

Because $A(x)$ is an integer and $\mathrm{ld}(R(x)) = \sum_{i=1}^{k} \frac{r_i}{p_i}$, the natural number b should be equal to the product of the different primes or should be equal to 1. Suppose that b is of this type. Then

$$\mathrm{ld}\left(4^{\lfloor \alpha \rfloor} \prod_{i=1}^{k} p_i^{c_i}\right) = \lfloor \alpha \rfloor + \sum_{i=1}^{k} \frac{c_i}{p_i} = \alpha$$

and we obtain a desired particular solution. If $y' = 0$ and x_0 any particular solution then

$$(x_0 y)' = x_0' y + x_0 y' = \alpha x_0 y,$$

also satisfies (6). Finally, if $x' = \alpha x$ and $y = \frac{x}{x_0}$ then

$$\mathrm{ld}(y) = \mathrm{ld}(x) - \mathrm{ld}(x_0) = 0$$

means that y is a solution of the equation $y' = 0$. ■

For instance the equation $x' = \frac{x}{4}$ has no solutions, $x_0 = \frac{2}{3}$ is a partial solution of the equation $x' = \frac{x}{6}$ and to obtain all nonzero solutions we need to multiply x_0 with any y such that $R(y) = 1, A(y) = 0$.

9 How to differentiate irrational numbers

The next step is to try to generalize our definition to irrational numbers. The equation (1) can still be used in the more general situation. But first we need to think about the correctness of the definition.

Lemma 1 *Let $\{p_1, \dots, p_k\}$ be a set of different primes and $\{x_1, \dots, x_k\}$ a set of rationals. Then*

$$P = \prod_{i=1}^{k} p_i^{x_i} = 1 \Leftrightarrow x_1 = x_2 = \cdots = x_k = 0.$$

Proof. It is evident if all x_i are integers, because the primes are different. If they are rational, let us choose a natural m such that all $y_i = mx_i$ are integer. Then $P^m = 1$ too and we get $y_i = 0 \Rightarrow x_i = 0$. ■

Now we can extend our definition to any real number x that can be written as a product $x = \prod_{i=1}^{k} p_i^{x_i}$ for different primes p_i and some nonzero rationals x_i. The previous lemma shows that this form is unique and as above we can define

$$x' = x \sum_{i=1}^{k} \frac{x_i}{p_i}.$$

The proof for the Leibnitz rule is still valid too and we skip it. For example we have

$$(\sqrt{3})' = (3^{1/2})' = 3^{1/2} \frac{1/2}{3} = \frac{\sqrt{3}}{6}.$$

More generally we have the following convenient formula:

Theorem 19 *Let x, y be rationals and x be positive. Then*

$$(x^y)' = yx^{y-1}x' = \frac{yx'}{x} x^y = yx^y ld(x). \tag{7}$$

Proof. If $x = \prod_{i=1}^{k} p_i^{x_i}$, then

$$(x^y)' = (\prod_{i=1}^{k} p_i^{yx_i})' = x^y \sum_{i=1}^{k} \frac{yx_i}{p_i} = yx^{y-1}x \sum_{i=1}^{k} \frac{x_i}{p_i} = yx^{y-1}x'.$$

■

An interesting corollary is

Corollary 4 *Let a, b, c, d be rationals such that $a^b = c^d$ (a, c being positive). Then*

$$b \cdot ld(a) = d \cdot ld(c)$$

and

$$a'bc = c'ad.$$

In particular, for the case $a = b, c = d$, we have

$$a^a = c^c \Rightarrow a' = c'.$$

■

As an example we can check directly that $x^y = y^x$ has the solutions

$$x = \left(\frac{m+1}{m}\right)^m; y = \left(\frac{m+1}{m}\right)^{m+1},$$

thus

$$\frac{x'}{x^2} = \frac{y'}{y^2},$$

so the equation $x' = \frac{x^2}{4}$ has at least two solutions obtained from $m = 1$.

Another example is

$$(1/2)^{1/2} = (1/4)^{1/4} \Rightarrow \left(\frac{1}{2}\right)' = \left(\frac{1}{4}\right)' = -\left(\frac{1}{4}\right).$$

In general it is not difficult to prove that all rational solutions of the equation $x^x = y^y$ have the form

$$x = \left(\frac{m}{m+1}\right)^m, y = \left(\frac{m}{m+1}\right)^{m+1}$$

for some natural m. Direct calculations give the same result as above:

$$x' = m\left(\frac{m}{m+1}\right)^{m-1}\left(\frac{m}{m+1}\right)' = (m+1)\left(\frac{m}{m+1}\right)^m\left(\frac{m}{m+1}\right)' = y'$$

and shows that this works even for rational m.

It would be natural to extend our definition to infinite products: if $x = \prod_{i=1}^{\infty} p_i^{x_i}$ is convergent then it is easy to show that the sum $x\sum_{i=1}^{\infty}\frac{x_i}{p_i}$ is also convergent. However, the problem is that the sum is not necessary convergent to zero, when $x = 1$. This is a reason why such a natural generalization of the derivative is not well-defined. Maybe a more natural approach is to restrict possible products, but we still do not know a nice solution of the problems that arise. But there is another way, which we consider in Section 11.

10 Arithmetic Derivative for UFD

The definition of the derivative and most of the proofs are based only on the fact that that every natural number has a unique factorization into primes. So it is not difficult to transfer it to an arbitrary UFD (unique factorization domain) R using the same definition: $p' = 1$ for every "canonical" prime (irreducible) element, the Leibnitz rule and additionally $u' = 0$ for all units (invertible elements) in R. For example we can do it for a polynomial ring $K[x]$ or for the Gaussian numbers $a + bi$. In the first case the canonical irreducible polynomials are monic, in the second the canonical primes are "positive" primes [3]. This leads to a well-defined derivative for the field of fractions. Note also, that even the condition UFD is not necessary – we only need to have a well-defined derivative, i.e. independent of factorization. We do not plan to develop the theory in this more abstract direction and restrict ourselves by the following trivial (but interesting) result.

Theorem 20 *Let K be a field of characteristic zero and with the derivative f' in $K[x]$ is defined as above. Let $\frac{d}{dx}$ be a usual derivative. Then $f'(x) = \frac{df(x)}{dx}$ if and only if the polynomial $f(x)$ is a product of linear factors.*

Proof. Because both derivatives are equal to zero on constants they coincide on linear polynomials. If $f(x)$ has no linear irreducible factors then $f'(x)$ has smaller degree then $\frac{df(x)}{dx}$. Otherwise $f(x) = l(x)g(x)$ for some linear polynomial $l(x)$ and

$$f'(x) - \frac{df(x)}{dx} = l'(x)g(x) + l(x)g'(x) - \frac{dl(x)}{dx}g(x) - l(x)\frac{dg(x)}{dx} =$$

$$l(x)\left(g'(x) - \frac{dg(x)}{dx}\right)$$

and we can use induction. ■

So, for the complex polynomials both definitions coincide. On the other hand $(x^2 + x + 1)' = \frac{d}{dx}(x^2 + x + 1) = 1$ in $\mathbf{Z_2}[x]$, though $(x^2 + x + 1)$ is irreducible, thus characteristic restrictions are essential.

Let us now look at the Gaussian numbers. We leave to the reader the pleasure of creating similar conjectures as for integers, for example the analogs of Goldbach and prime twins conjectures (twins seem to be pairs with distance $\sqrt{2}$ between two elements; more history and variants can be found in "The Gaussian zoo" [5]). We go into another direction.

Note, that because $2+i$ and $2-i$ are "positive" primes and $5 = (2+i)(2-i)$, we should have $5' = (2+i) + (2-i) = 4$, but this does not coincide with the earlier definition. So it may be is time to change our point of view radically.

11 Generalized derivatives

Our definition is based on two key points – the Leibnitz rule and $p' = 1$ for primes. If we skip the second one and use the Leibnitz rule only we get a more general definition of $D(x)$. Now, if $x = \prod_{i=1}^{k} p_i^{x_i}$, then

$$D(x) = x\sum_{i=1}^{k}\frac{x_i D(p_i)}{p_i},$$

and we can again repeat most of the proofs above. But it is much more natural to use another approach.

Theorem 21 *Let R be a commutative ring without zero divisors and let $L : R^* \longrightarrow R^+$ be a homomorphism of its multiplicative semigroup to the additive group. Then a map*

$$D : R \longrightarrow R, D(x) = xL(x), D(0) = 0$$

satisfies the Leibnitz rule. Conversely, if $D(xy) = D(x)y + xD(y)$ then $L(x) = \frac{D(x)}{x}$ is a homomorphism. If R is a field then L is a group homomorphism and

$$D\left(\frac{x}{y}\right) = \frac{D(x)y - xD(y)}{y^2}.$$

Proof.

$$D(xy) - D(x)y - xD(y) = xyL(xy) - xL(x)y - xyL(y) = xy(L(xy) - L(x) - L(y))$$

and we see that the Leibnitz rule is equivalent to the homomorphism condition. If R is a field then the semigroup homomorphism is automatically the group homomorphism and $L(1/x) = -L(x)$ which is sufficient to get

$$D\left(\frac{1}{y}\right) = \left(\frac{1}{y}\right)(-L(y)) = \frac{-D(y)}{y^2}.$$

Then it remains to repeat the proof of Theorem 14. ■

Corollary 5 *There exist infinitely many possibilities to extend the derivative x', constructed in Section 9 on* $\mathbf{Q}$ *to all real numbers preserving the Leibnitz rule.*

Proof. We start from the positive numbers. It is sufficient to extend $ld(x)$. Note that the multiplicative group of positive real numbers is isomorphic to the additive group and both of them are vector spaces over rationals. In Section 9 a map $ld(x)$ is defined over a subspace and there are infinitely many possibilities to extend a linear map from a subspace to the whole space. Obviously it would be a group homomorphism and this gives a derivative for positive numbers. For the negative numbers we proceed as in Section 5. ■

Note that the Axiom of Choice is being used here. It would be nice to find some "natural" extension, which preserves condition (7), but note that no such extension can be continuous. To show this let us consider a sequence

$$x_n = \frac{2^{a_n}}{3^n}, a_n = \lfloor n \log_2 3 \rfloor.$$

It is bounded and has a convergent subsequence (even convergent to 1.) But

$$\lim_{n\to\infty} (x_n)' = \lim_{n\to\infty} x_n \left(\frac{a_n}{2} - \frac{n}{3}\right) = \infty.$$

An example of continuous generalized derivative gives us $D(x) = x \ln x$. It is easy to construct a surjective generalized derivative in the set of integers, and is impossible to make it injective (because $D(1) = D(-1) = D(0) = 0$). But probably even the following conjecture is true.

Conjecture 15 *There is no generalized derivative $D(x)$ which is bijection between the set of natural numbers and the set of nonnegative integers.*

We can even hope for a stronger variant:

Conjecture 16 *For any generalized derivative $D(x)$ on the set of integers there exist two different positive integers which have the same derivative.*

Returning to the generalized derivatives in $\mathbf{Q}$ or $\mathbf{R}$ let us investigate their structure as a set.

Theorem 22 *If D_1, D_2 are two generalized derivatives and a, b are some real numbers then $aD_1 + bD_2$ and $[D_1, D_2] = D_1D_2 - D_2D_1$ are generalized derivatives too. Nevertheless the set of all generalized derivatives is* not *a Lie algebra.*

Proof. We have

$$(aD_1 + bD_2)(xy) = aD_1(xy) + bD_2(xy) = aD_1(x)y + axD_1(y) + bD_2(x)y + bxD_2(y) =$$

$$aD_1(x)y + bD_2(x)y + xaD_1(y) + xbD_2(y) = (aD_1 + bD_2)(x)y + x(aD_1 + bD_2)(y).$$

In the same way:

$$[D_1, D_2](xy) = (D_1D2 - D_2D_1)(xy) = D_1D_2(xy) - D_2D_1(xy) =$$

$$D_1(D_2(x)y + xD_2(y)) - D_2(D_1(x)y + xD_1(y)) =$$
$$D_1(D_2(x))y + D_2(x)D_1(y) + D_1(x)D_2(y) + xD_1(D_2(y)) -$$
$$(D_2(D_1(x))y + D_1(x)D_2(y) + D_2(x)D_1(y) + xD_2(D_1(y))) =$$
$$D_1(D_2(x))y + xD_1(D_2(y)) - D_2(D_1(x))y - xD_2(D_1(y)) =$$
$$[D_1, D_2](x)y + x[D_1, D_2](y).$$

But the commutator is not bilinear: in general

$$[aD_1 + bD_2, D_3] \neq a[D_1, D_3] + b[D_2, D_3]$$

so we have no Lie algebra structure. ■

Let us define $D_{(p_i)}$ as a derivative which maps a prime p_i to 1 and other primes p_j to zero. Then $[D_{(p_i)}, D_{(p_j)}] = 0$, but already $[3D_{(2)}, D_{(3)}] = -D_{(2)}$. Nevertheless every generalized derivative D can be uniquely written as

$$D = \sum_{i=1}^{\infty} D(p_i)D_{(p_i)}.$$

12 The generating function

Let $D(x)$ be a generalized derivative over the reals and $L(x) = \frac{D(x)}{x}$ be corresponding logarithmic derivative. Let

$$H_D(t) = \sum_{n=0}^{\infty} D(n)t^n, H_L(t) = \sum_{n=1}^{\infty} L(n)t^n$$

be their generating functions.

Theorem 23 *The generating functions $H_D(t), H_L(t)$ can be be calculated as follows:*

$$H_D(t) = t\frac{d}{dt}\left(H_L(t)\right).$$

$$H_L(t) = \sum_p{}' L(p) \sum_{j=1}^{\infty} \frac{t^p}{1-t^{p^j}},$$

where the first sum runs over all primes.

Proof. The first formula is equivalent to the condition $D(n) = n \cdot L(n)$. As to the second formula it is sufficient to prove it for the special case when $L(p) = 1$ for some prime p and $L(q) = 0$ for all other primes. Then we need to prove that

$$\sum_{n=0}^{\infty} L(n)t^n = \sum_{j=1}^{\infty} \frac{t^p}{1-t^{p^j}}.$$

If $n = p^k m$ and $\gcd(p, m) = 1$ then t^n appears exactly in k sums

$$\frac{t^p}{1-t^{p^j}} = \sum_{i=1}^{\infty} t^{ip^j}$$

for $j = 1, 2, \ldots, k$. It only remains to note that $L(n) = k$. ■

Corollary 6

$$L(n!) = \sum_{i=1}^{n} L(i) = \sum_{p\le n}{}' L(p) \sum_{j=1}^{\infty} \left\lfloor \frac{n}{p^j} \right\rfloor.$$

Proof. If we replace every $\frac{t^p}{1-t^{p^j}}$ by $\sum_{i=1}^{\lfloor \frac{n}{p^j} \rfloor} t^{ip^j}$ we do not change the coefficients in t^k for $k \le n$ and make them equal to zero for $k > n$. So it is sufficient to put $t = 1$ to get the desired $\lfloor \frac{n}{p^j} \rfloor$ in every summand. ■

If we use the same $L(x)$ that we used in the proof of the Theorem 23, we get the classical Legendre theorem that calculates the maximal power of a prime p in $n!$.

On the other hand if we use $L(x) = \mathrm{ld}(x)$ we will be able, following Barbeau [1], to estimate $\sum_{i=1}^{n} \mathrm{ld}(i)$. Let $m = \lfloor \log_2 n \rfloor$. Then we can change infinity in our sums to m. Using standard estimates

$$\sum_{p\le n}{}' \frac{1}{p} = O(\ln m),$$

$$\sum_{p>n}{}' \frac{n}{p(p-1)} < \sum_{k>n} \frac{n}{k(k-1)} = \sum_{k>n} n\left(\frac{1}{k} - \frac{1}{k-1}\right) \le 1,$$

$$\sum_{p\le n}{}' \frac{n}{p^{m+1}(p-1)} < \sum_{p\le n}{}' \frac{2n}{2^{m+1}p(p-1)} < \sum_{k\le n} \frac{2n}{nk(k-1)} \le 2,$$

we get

$$\sum_{i=1}^{n} \mathrm{ld}(i) = \sum_{p\le n}{}' \frac{1}{p} \sum_{j=1}^{m} \left\lfloor \frac{n}{p^j} \right\rfloor = \sum_{p\le n}{}' \frac{1}{p} \left(\sum_{j=1}^{m} \frac{n}{p^j} + O(m) \right) =$$

$$\sum_{p\le n}{}' \frac{n}{p^{m+1}} \left(\frac{p^m - 1}{p-1} \right) + O(\ln m)O(m) = \sum_{p}{}' \frac{n}{p(p-1)} -$$

$$-\sum_{p>n}{}' \frac{n}{p(p-1)} - \sum_{p\le m}{}' \frac{n}{p^{m+1}(p-1)} + O(\ln m)O(m) =$$

$$\sum_{p}{}' \frac{n}{p(p-1)} + O(m \ln m).$$

Theorem 24 *[1] Let*

$$C = \sum_{p}{}' \frac{1}{p(p-1)} = 0.749\ldots$$

Then

$$ld(n!) = \sum_{i=1}^{n} ld(i) = Cn + O\left((\ln n)(\ln\ln n)\right)$$

$$\sum_{k=1}^{n} k' = \frac{C}{2} n^2 + O(n^{1+\delta})$$

for any $\delta > 0$.

Proof. The first formula is already proved. As to the second we have

$$\sum_{k=1}^{n} k' = \sum_{k=1}^{n} k \cdot \mathrm{ld}(k) = \sum_{k=1}^{n} \sum_{i=k}^{n} \mathrm{ld}(i) =$$

$$\sum_{k=1}^{n} (\mathrm{ld}(n!) - \mathrm{ld}((k-1)!)) = n\mathrm{ld}(n!) - \sum_{k=1}^{n-1} \mathrm{ld}(k!) =$$

$$n(Cn + O(n^{\delta})) - \sum_{k=1}^{n-1} (Ck + O(n^{\delta})) =$$

$$Cn^2 - C\frac{n(n-1)}{2} + O(n^{1+\delta}) = \frac{C}{2} n^2 + O(n^{1+\delta}).$$

■

We leave to the reader the pleasure to play with $\zeta_D(s) = \sum \frac{n'}{n^s}$.

13 Logical dependence of the conjectures

Here we would like to exhibit some of the logical dependence between the different conjectures we have mentioned above. As we see the Conjectures 8 and 9 seem to be the key problems.

Theorem 25 *The following picture describes the logical dependence between the different conjectures.*

$$\begin{array}{c} (2) \Rightarrow (3) \Rightarrow (4), \\ (12) \Rightarrow (13), \\ (5) \Leftarrow (6, \textit{Goldbach}), \\ (15) \Leftarrow (16), \\ \begin{array}{ccccc} & & (11, \textit{Triples}) & & (8) \\ & & \Downarrow & & \Downarrow \\ (10, \textit{Twins}) & \Rightarrow & (9) & \Rightarrow & (1) \end{array} . \end{array}$$

Additionally if Conjecture 1 is valid then either Conjecture 8 or Conjecture 9 is valid (or both).

Proof. The only nontrivial dependence is the last one. Suppose that Conjecture 9 is wrong, but Conjecture 1 is true. We need to show that Conjecture 8 is valid. Let Γ be the tree having vertices 1 (the root), the primes p with $i(p) > 0$ and all composite n with $n^{(k)} = 0$ for some $k \geq 1$. Further, let Γ have edges from n to n'. By Conjecture 1, Γ is infinite. By Theorem 8 and Corollary 3 the degree at each vertex different from 1 is finite. Also the vertex 1 has finite degree since 9 is false. By Köning infinity lemma Γ contains an infinite chain, ending in 1, which is Conjecture 8. ■

14 Concluding remarks

This article is our expression of the pleasure being a mathematician. We have written it because we found the subject to be very attractive and wanted to share our joy with others. To our surprise we did not find many references. In the article of A. Buium [2] and other articles of this author (which are highly recommended) we at least have found that there exists authors who can imagine a derivative without the linearity property. But the article of E. J. Barbeau [1] was the only article that has direct connection to our topic. Most of the material from this article we have repeated here (not always citing). We omitted only the description of the numbers with derivatives that are divisible by 4 and his conjecture that for every n there exists a prime p such that all derivatives $n^{(k)}$ are divisible by p for sufficiently large k. In fact according to Theorems 4, 5 it is equivalent to be divisible by p^p for sufficiently large k. Thus this conjecture is a bit stronger then Conjecture 2.

The definition of the arithmetic derivative itself and its elementary properties was already in the Putnam Prize competition (it was Problem 5 of the morning session in March 25, 1950, [4]) and probably was known in folklore even earlier. What we have done is mainly to generalize this definition in different directions, to solve some differential equations, to

calculate the generating function and to invite the reader to continue work in this area. We are grateful to our colleagues for useful discussion, especially to G. Almkvist, A. Chapovalov, S. Dunbar, G. Galperin, S. Shimorin and the referee, who helped to improve the text. We are especially grateful to J. Backelin, who helped us to reduce the number of conjectures by suggesting ideas that translated them into theorems.

Abstract. In this paper we determine those squares whose decimal representation consists of $k \geq 2$ digits such that $k-1$ of them equal.

1 Introduction

R. Obláth [5] succeeded in almost entirely solving the problem of finding all the numbers n^m $(n, m \in \mathbb{N},\ n \geq 2,\ m \geq 2)$ that have equal digits. The special case $m = 2$ is a very well known result, although its proof involves no difficulty. In this connection, the following question naturally arises: is it possible to determine all of the squares having all digits but one equal?

The answer is given by

Theorem 1.1 *The squares whose decimal representation makes use of $k \geq 2$ digits, such that $k-1$ of these digits are equal, are precisely* 16, 25, 36, 49, 64, 81, 121, 144, 225, 441, 484, 676, 1444, 44944, 10^{2i}, $4 \cdot 10^{2i}$ *and* $9 \cdot 10^{2i}$ *with* $i \geq 1$.

When we are looking for the squares with k digits among which $k-1$ digits equal 0, we immediately get that the corresponding numbers are 10^{2i}, $4 \cdot 10^{2i}$ and $9 \cdot 10^{2i}$ with $i \geq 1$.

A simple computation shows that the numbers with at most 4 digits verifying the condition in the statement are just the ones listed above.

Since every natural number can be written in the form $50000k \pm r$ with $0 \leq r \leq 25000$, and $(50000k \pm r)^2 \equiv r^2 \pmod{100000}$, we compute r^2 for $r \leq 25000$ and find that the last 4 digits of any square can be equal only when all of them equal 0, which solves Obláth's problem for squares having $k \geq 4$ digits.

We select the squares such that 4 of the last 5 digits are equal, because these point out the possible squares with $k \geq 5$ digits, $k-1$ digits of them being equal. If one excludes the numbers for which there are $k-1$ digits equal to 0, then there still remain 22 types of numbers, namely:

$a_1 = 1\cdots121$	$a_7 = 4\cdots441$	$a_{13} = 4\cdots4944$	$a_{18} = 7\cdots76$
$a_2 = 1\cdots161$	$a_8 = 4\cdots449$	$a_{14} = 4\cdots45444$	$a_{19} = 8\cdots81$
$a_3 = 2\cdots224$	$a_9 = 4\cdots464$	$a_{15} = 4\cdots49444$	$a_{20} = 8\cdots89$
$a_4 = 2\cdots225$	$a_{10} = 4\cdots484$	$a_{16} = 5\cdots56$	$a_{21} = 9\cdots929$
$a_5 = 4\cdots41444$	$a_{11} = 4\cdots4544$	$a_{17} = 6\cdots656$	$a_{22} = 9\cdots969$
$a_6 = 4\cdots4144$	$a_{12} = 4\cdots4644$		

One will show that, among these numbers with $k \geq 5$ digits, only 44944 is a square. The exclusion of the other numbers can be carried out fairly easily in certain cases, as we show in §2. In the other cases we will solve equations of the type

$$x^2 - dy^2 = k \tag{1}$$

(where $d, k \in \mathbb{Z}^*$, $d > 0$ and $\sqrt{d} \notin \mathbb{Z}$) in integers. The literature concerning equation (1) is rather extensive. In this connection, we mention [1, 2, 3, 4].

We now recall the solving method (in accordance with [2]). We denote by (r, s) the minimal positive solution to the equation

$$x^2 - dy^2 = 1 \tag{2}$$

and by $\varepsilon = r + s\sqrt{d}$. We determine the "small" solutions to equation (1) (if any). They generate all the solutions.

Theorem 1.2 *We denote by $\mu_i = a_i + b_i\sqrt{d}, i = \overline{1,m}$ all the numbers with the property that (a_i, b_i) is a solution in nonnegative integers to equation (1) with $a_i \leq \sqrt{|k|\varepsilon}$ and $b_i \leq \sqrt{\varepsilon|k|/d}$ (if any). If x and y are solutions to (1) then there exist $i, n \in \mathbb{Z}$ such that $1 \leq i \leq m$ and $x + y\sqrt{d} = \pm\mu_i\varepsilon^n$ or $x + y\sqrt{d} = \pm\bar{\mu}_i\varepsilon^n$.*

We will use this theorem in §3.

2 Excluding the simple cases

We assume in this section that $k \geq 5$ and a_n is a square, hence $9a_n$ is a square as well. Make use of simple reasonings, we shall show that this fact is impossible. To this end, we use the symbol of Legendre in some cases.

The 16 cases which have to be excluded will be exposed in a concise form, inasmuch as some of them are quite similar:

$$a_3, a_4, a_{20};\ a_2, a_{15}, a_{18};\ a_{11}, a_{17}.$$

We mention that each of the cases below is concluded by a contradictory assertion, thus proving the impossibility of the corresponding case.

1. We have $9a_2 = 10^k + 449 \equiv (-1)^k + 9 \pmod{11}$. But $\left(\frac{8}{11}\right) = \left(\frac{10}{11}\right) = -1$.

2. It follows by $9a_3 = 2(10^k + 8) = (4x)^2$ that $2^{k-3}5^k = (x-1)(x+1)$. Since $(x-1, x+1) = 2$, we have $5^k \mid x + \varepsilon$ with $\varepsilon \in \{-1, 1\}$, whence $x + 1 \geq 5^k$. Consequently $2^{k-3} \cdot 5^k = x^2 - 1 \geq 5^k(5^k - 2)$, hence $2^{k-3} \geq 5^k - 2$.

3. By $9a_4 = 2 \cdot 10^k + 25 = (5x)^2$, we have $2^{k+1} \cdot 5^{k-2} = (x-1)(x+1)$, whence $2^{k+1} \cdot 5^{k-2} \geq 5^{k-2}(5^{k-2} - 2)$.

4. We have $9a_5 = 4 \cdot 10^k - 27004 = (2x)^2$, whence $10^k - 6751 = x^2$. When k is an odd number, we have $10^k - 6751 \equiv 2 \pmod{11}$, but $\left(\frac{2}{11}\right) = -1$. If $k = 2h$ with $h \geq 3$, then $(10^h - x)(10^h + x) = 6751$, whence $10^h - x = a$, $10^h + x = b$, where we have either $(a, b) = (1, 6751)$ or $(a, b) = (43, 157)$. Since $2 \cdot 10^h = a + b$, it follows that either $2 \cdot 10^h = 6752$ or $2 \cdot 10^h = 200$, although $h \geq 3$.

5. By $9a_6 = 4 \cdot 10^k - 2704 = (4x)^2$ it follows that $5^2 \cdot 10^{k-2} - 169 = x^2$. Since $k \geq 5$, we get that $x^2 = 5^2 \cdot 10^{k-2} - 169 \overset{4}{\equiv} -169 \overset{4}{\equiv} 3$.

6. We have $a_9 = 4 \cdot 11 \cdots 16$, but $11 \cdots 16$ does not occur among the numbers a_i.

7. We have $a_{10} = 4a_1$, and we shall get the contradiction after we study a_1 for $k \geq 5$.

8. We have $9a_{11} = 4 \cdot 10^k + 896 = (8x)^2$, hence $2^{k-4}5^k + 14 = x^2$. It follows that $x \vdots 2$. Therefore $x^2 \vdots 4$, and $k = 5$. In this case we get $x^2 = 6264$.

9. We have $a_{12} = 4a_2$, but $a_2 \neq x^2$.

10. By $9a_{15} = 4 \cdot 10^k + 44996 = (2x)^2$ it follows that $10^k + 11249 = x^2$. Then $10^k + 11249 \equiv (-1)^k + 7 \pmod{11}$, but $\left(\frac{6}{11}\right) = \left(\frac{8}{11}\right) = -1$.

11. Since $4a_{16} = \underbrace{22 \cdots 2}_{k}4$ and $a_3 \neq x^2$, it follows that $a_{16} \neq y^2$.

12. We have $9a_{17} = 6 \cdot 10^k - 96 = (4x)^2$, hence $3 \cdot 2^{k-3}5^k - 6 = x^2$. But $x^2 \vdots 4$ and $3 \cdot 2^{k-3}5^k \vdots 4$ (because $k \geq 5$).

13. We have $9a_{18} = 7 \cdot 10^k - 16 \equiv 7(-1)^k - 5 \pmod{11}$. But $\left(\frac{2}{11}\right) = \left(\frac{10}{11}\right) = -1$.

14. By $9a_{20} = 8 \cdot 10^k + 1 = x^2$ it follows that $(x-1)(x+1) = 2^{k+3}5^k$ and then $2^{k+3}5^k \geq 5^k(5^k - 2)$.

15. We have $a_{21} \equiv 2 \pmod{9}$.

16. We have $a_{22} \equiv 6 \pmod{9}$.

3 The six difficult cases

Just as in the previous cases, the numbers under consideration have $k \geq 5$ digits, and $k - 1$ of these digits are equal.

1. For $a_1 = 11 \cdots 121 = x^2$ it follows that $(10^k - 1)/9 + 10 = x^2$. We denote $y = 3x$ and, since $k \geq 5$, we have $y > 316$ and

$$10^k - y^2 = -89. \tag{3}$$

For $k = 2m$ we have $(10^m - y)(10^m + y) = -89$, whence we get both $10^m - y = -1$ and $10^m + y = 89$, which is a contradiction.

For $k = 2m + 1$, we denote $z = 10^m$ and then

$$y^2 - 10z^2 = 89.$$

The primitive solution of the Pell equation

$$x^2 - 10y^2 = 1$$

is $(r, s) = (19, 6)$. Making use of Theorem 1.2 in the Introduction, we get $b_i \leq \sqrt{\frac{89}{10}\left(19 + 6\sqrt{10}\right)}$, hence $b_i \leq 18$. We find $b_1 = 8, a_1 = 27$, and $b_2 = 10, a_2 = 33$.

It follows that either

$$y + z\sqrt{10} = \left(\pm 27 \pm 8\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t$$

or

$$y + z\sqrt{10} = \left(\pm 33 \pm 10\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t,$$

with $t \in \mathbb{Z}$. Since $y > 0$, $z > 0$, we have only the solutions

$$y + z\sqrt{10} = \left(27 \pm 8\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t$$

and

$$y + z\sqrt{10} = \left(33 \pm 10\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t,$$

with $t \in \mathbb{Z}$. Since $\frac{27+8\sqrt{10}}{19+6\sqrt{10}} < 2$ and $\frac{33+10\sqrt{10}}{19+6\sqrt{10}} < 2$, it follows that $t \in \mathbb{N}$. Let $\left(19 + 6\sqrt{10}\right)^t = a_t + b_t\sqrt{10}$, $a_t, b_t \in \mathbb{N}$, $a_0 = 1, b_0 = 0$. For $t \geq 1$, we have the following equalities:

$$a_t = 19^t + C_t^2 19^{t-2} \cdot 6^2 \cdot 10 + \cdots \tag{4}$$

and

$$b_t = C_t^1 19^{t-1} \cdot 6 + C_t^3 19^{t-3} \cdot 6^3 \cdot 10 + \cdots . \tag{5}$$

We have $a_t \equiv 1 \pmod 3$ and $b_t \equiv 0 \pmod 3$. Since $z = 10^m \equiv 1 \pmod 3$, we only have one of the situations

$$y + z\sqrt{10} = \left(27 - 8\sqrt{10}\right)\left(19 + 6\sqrt{10}\right), \quad t \in \mathbb{N}, \tag{6}$$

and

$$y + z\sqrt{10} = \left(33 + 10\sqrt{10}\right)\left(19 + 6\sqrt{10}\right), \quad t \in \mathbb{N}. \tag{7}$$

a) In the case of the relation (6), we have the identity

$$z = 10^m = 27b_t - 8a_t. \tag{8}$$

Since $k \geq 5$, it follows that $m \geq 2$.

For $m = 2$, the equation (3) takes the form $y^2 - 10^5 = 89$, and has no integer solutions.

For $m \geq 3$, it follows that $8 \mid b_t$. By (5) we have $b_t \equiv 6t \cdot 19^{t-1} \pmod 8$, whence $t = 4h$. It then follows by (4) and (5) that

$$a_t \equiv 6^{4h} \cdot 10^{2h} \pmod{19} \text{ and } 19 \mid b_t.$$

By (8) we get $10^m \equiv -8 \cdot 6^{4h} \cdot 10^{2h} \pmod{19}$, whence

$$\left(\frac{10^m}{19}\right) = \left(\frac{-8 \cdot 6^{4t} \cdot 10^{2h}}{19}\right) = \left(\frac{-2}{19}\right) = 1.$$

Since $\left(\frac{10}{19}\right) = \left(\frac{-9}{19}\right) = (-1) \cdot \left(\frac{3^2}{19}\right) = -1$, it follows that $m = 2f$.

The equation (3) takes the form

$$10^{4f+1} + 89 = y^2. \tag{9}$$

We have $10^4 \equiv 1 \pmod{101}$, hence $10^{4f+1} \equiv 10 \pmod{101}$. In view of (9), it follows that

$$y^2 \equiv 99 \pmod{101}.$$

But $\left(\frac{99}{101}\right) = \left(\frac{-2}{101}\right) = \left(\frac{2}{101}\right) = -1$, and thus a contradiction.

b) It follows by (7) that

$$z = 10^m = 33b_t + 10a_t. \tag{10}$$

Since $m \geq 3$, it follows that $b_t + 2a_t \equiv 0 \pmod 8$. By (4) and (5) we have $a_t \equiv 19^t \pmod 8$ and $b_t \equiv 6t \cdot 19^{t-1} \pmod 8$. Therefore $6t \cdot 19^{t-1} + 2 \cdot 19^t \equiv 0 \pmod 8$, which in turn implies $3t+19 \equiv 0 \pmod 4$ and $t = 4h+3$. Now (4), (5) and (10) imply that $10^m \equiv 33 \cdot 6^{4h+3} \cdot 10^{2h+1} \pmod{19}$, whence

$$\begin{aligned}\left(\frac{10^m}{19}\right) &= \left(\frac{33 \cdot 6 \cdot 10}{19}\right) = \left(\frac{3^2 \cdot 2^2 \cdot 55}{19}\right) \\ &= \left(\frac{55}{19}\right) = \left(\frac{-2}{19}\right) = -\left(\frac{2}{19}\right) = -(-1)^{(19^2-1)/8} \\ &= 1.\end{aligned}$$

Consequently $m = 2f$, and we get (9) again, which is a contradiction.

2. For $a_7 = 44 \cdots 41 = x^2$ it follows that $4 \cdot \frac{10^k - 1}{9} - 3 = x^2$, hence

$$4 \cdot 10^k - y^2 = 31, \tag{11}$$

where $y = 3x$.

If $k = 2m$, then $(2 \cdot 10^m - y)(2 \cdot 10^m + y) = 31$. Hence

$$2 \cdot 10^m - y = 1 \text{ and } 2 \cdot 10^m + y = 31,$$

which is a contradiction. If $k = 2m + 1$ then, denoting $z = 2 \cdot 10^m$, we get the equation

$$y^2 - 10z^2 = -31.$$

Just as in the previous case, we make use of Theorem 1.2 and, for $y > 0$, $z > 0$, we get that either

$$y + z\sqrt{10} = \left(3 + 2\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t \tag{12}$$

or

$$y + z\sqrt{10} = \left(-3 + 2\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t, \tag{13}$$

with $t \in \mathbb{N}$.

a) By (12) we obtain the equation:

$$2 \cdot 10^m = 3b_t + 2a_t. \tag{14}$$

Since $m \geq 2$, it follows by (5), (6) and (14) that $3 \cdot 6t \cdot 19^{t-1} + 2 \cdot 19^t \equiv 0 \pmod 8$, that is, $9t + 19 \equiv 0 \pmod 4$, whence $t = 4h + 1$. By (4) and (5) we get that $z \equiv 3 \cdot 6^{4h+1} \cdot 10^{2h} \pmod{19}$, that is, $10^m \equiv 3^2 \cdot 6^{4h} \cdot 10^{2h} \pmod{19}$, whence $\left(\frac{10^m}{19}\right) = 1$. Consequently m is an even number.

On the other hand, it follows by (14) that $3b_t + 2a_t \equiv 0 \pmod 5$, that is, $a_t \equiv b_t \pmod 5$. By (4) and (5) it follows that $a_t \equiv (-1)^t \pmod 5$ and $b_t \equiv (-1)^{t-1}t \pmod 5$, whence $t \equiv 4 \pmod 5$. We have $(3 + \sqrt{10})^5 = 4443 + 1405\sqrt{10} \equiv -53 \pmod{281}$, hence $(19 + 6\sqrt{10})^5 = \left((3 + \sqrt{10})^5\right)^2 \equiv 53^2 \equiv -1 \pmod{281}$. Consequently

$$\begin{aligned} y + 2 \cdot 10^m\sqrt{10} &= \left(3 + 2\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^{t+1}\left(19 - 6\sqrt{10}\right) \\ &= \left(-63 + 20\sqrt{10}\right)\left[\left(19 + 6\sqrt{10}\right)^5\right]^{(t+1)/5} \\ &\equiv -63 + 20\sqrt{10} \pmod{281}. \end{aligned}$$

We have taken into account that $t \equiv 4 \pmod 5$ and t is an odd number.

We have $2 \cdot 10^m \equiv 20 \pmod{281}$, that is, $10^{m-1} \equiv 1 \pmod{281}$. Since $10^7 \equiv 53 \pmod{281}$, it follows that $10^{14} \equiv -1 \pmod{281}$ and $10^{28} \equiv 1 \pmod{281}$. Thus we have $\operatorname{ord} \overline{10} = 28$ in $\mathbb{Z}_{281}$, whence $28 \mid m - 1$, which is a contradiction since m is even.

b) It follows by (13) that

$$2 \cdot 10^m = -3b_t + 2a_t. \tag{15}$$

Since $m \geq 2$, it follows that $-3b_t + 2a_t \equiv 0 \pmod 8$. We get by (4) and (5) that $t = 4h + 3$ and then $2 \cdot 10^m \equiv -3 \cdot 6^{4h+3} \cdot 10^{2h+1} \pmod{19}$. Therefore $\left(\frac{10^m}{19}\right) = 1$, and m is even. Also by (15) we get $a_t + b_t \equiv 0 \pmod 5$, and in view of (4) and (5) we have $t \equiv 1 \pmod 5$. The relation (13) can be written as:

$$\begin{aligned} y + 2 \cdot 10^m\sqrt{10} &= \left(-3 + 2\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^{t-1}\left(19 + 6\sqrt{10}\right) \\ &= \left(63 + 20\sqrt{10}\right)\left(\left(19 + 6\sqrt{10}\right)^5\right)^{(t-1)/5} \\ &\equiv 63 + 20\sqrt{10} \pmod{281}. \end{aligned}$$

Just as in the case *a)*, it follows that $2 \cdot 10^m \equiv 20 \pmod{281}$. The relation $10^{m-1} \equiv 1 \pmod{281}$ contradicts the fact that m is even.

3. For $a_8 = 44\cdots49 = x^2$ we have $4\cdot\frac{10^k-1}{9}+5 = x^2$. We denote $3x = y$ and then

$$4\cdot 10^k + 41 = y^2.$$

For $k = 2m$, we get the equalities $y-2\cdot10^m = 1$ and $y+2\cdot10^m = 41$, which is a contradiction because $m \geq 2$.

For $k = 2m+1$ we set $z = 2\cdot10^m$, and then $y^2 - 10z^2 = 41$. Whence for $y > 0$ and $z > 0$ we get either

$$y + 2\cdot10^m\sqrt{10} = \left(9-2\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{16}$$

or

$$y + 2\cdot10^m\sqrt{10} = \left(9+2\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{17}$$

where t is a natural number.

a) It follows by (16) that

$$2\cdot10^m = 9b_t - 2a_t.$$

Since $2\cdot10^m \equiv 2 \pmod 3$, and on the other hand we have by (4) that $a_t \equiv 1 \pmod 3$, we get the contradiction $2 \equiv -2 \pmod 3$.

b) It follows by (17) that

$$2\cdot10^m = 2a_t + 9b_t. \tag{18}$$

Then $b_t \equiv 2a_t \pmod 5$, whence $t \equiv 3 \pmod 5$. We also have $b_t + 2a_t \equiv 0 \pmod 4$, hence t is odd.

The equality (17) takes the form

$$\begin{aligned} y + 2\cdot10^m\sqrt{10} &= \left(9+2\sqrt{10}\right)\left(19+6\sqrt{10}\right)^{t+2}\left(19-6\sqrt{10}\right)^2 \\ &= \left(1929-610\sqrt{10}\right)\left[\left(19+6\sqrt{10}\right)^5\right]^{(t+2)/5} \\ &\equiv 38+48\sqrt{10} \pmod{281}, \end{aligned}$$

since $(t+2)/5$ is odd and $\left(19+6\sqrt{10}\right)^5 \equiv -1 \pmod{281}$.

Thus $2\cdot10^m \equiv 48 \pmod{281}$, hence $\left(\frac{2\cdot10^m}{281}\right) = \left(\frac{48}{281}\right)$. Therefore,

$$(-1)^{\frac{281^2-1}{8}(m+1)}\left(\frac{5^m}{281}\right) = \left(\frac{3}{281}\right).$$

We have $\left(\frac{5}{281}\right) = \left(\frac{281}{5}\right) = \left(\frac{1}{5}\right) = 1$ and $\left(\frac{3}{281}\right) = \left(\frac{281}{3}\right) = \left(\frac{2}{3}\right) = -1$, hence a contradiction.

4. For $a_{13} = 44\cdots4944 = x^2$, we have $4\cdot\frac{10^k-1}{9}+500 = x^2$, that is, $y^2 - 25\cdot10^{k-2} = 281$, where $y = \frac{3}{4}x$.

If $k = 2m+2$, then $(y-5\cdot10^m)(y+5\cdot10^m) = 281$, whence $y-5\cdot10^m = 1$ and $y+5\cdot10^m = 281$. One gets the contradiction $10^{m+1} = 280$.

If $k = 2m+3$, we denote $z = 5\cdot10^m$. We have $m \geq 1$ and

$$y^2 - 10z^2 = 281 \tag{19}$$

whence either

$$y + z\sqrt{10} = \left(21 + 4\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t, \quad t \in \mathbb{N}, \tag{20}$$

or

$$y + z\sqrt{10} = \left(21 - 4\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^t, \quad t \in \mathbb{N}^*. \tag{21}$$

a) By (20) it follows that

$$5 \cdot 10^m = 21b_t + 4a_t,$$

hence $5 \cdot 10^m \equiv 4a_t \pmod 3$. Since $a_t \equiv 1 \pmod 3$, we get the contradiction $5 \equiv 4 \pmod 3$.

b) By (21), if $t = 1$ then $y = 159$ and $z = 50$, whence $m = 1$ and then $k = 5$. One thus get the number

$$44944 = 212^2.$$

For $t \geq 2$, it follows that $y + \sqrt{10} \cdot 5 \cdot 10^m = \left(159 + 50\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^s$, $s \geq 1$, hence

$$5 \cdot 10^m = 159b_s + 50a_s. \tag{22}$$

For $m = 0$ and $m = 2$, equation (19) has no integer solutions, hence we may consider $m \geq 3$. We have by (22) that $b_s \equiv 2a_s \pmod 8$. Hence it follows by (4) and (5) that $6s \cdot 19^{s-1} \equiv 2 \cdot 19^s \pmod 8$. Therefore $3s \equiv 19 \pmod 4$ and $s = 4h + 1$. Also by (22) we have $5 \cdot 10^m \equiv 159 \cdot 6^s \cdot 10^{2h} \pmod{19}$, hence $\left(\frac{5 \cdot 10^m}{19}\right) = \left(\frac{159}{19}\right)\left(\frac{6^s}{19}\right) = \left(\frac{7}{19}\right)$, because $\left(\frac{6}{19}\right) = 1$. Since

$$\left(\frac{5}{19}\right) = \left(\frac{-14}{19}\right) = (-1)^{\frac{19-1}{2}}(-1)^{\frac{19^2-1}{8}}\left(\frac{7}{19}\right) = \left(\frac{7}{19}\right),$$

we have $\left(\frac{10^m}{19}\right) = 1$, that is, $\left(\frac{10}{19}\right)^m = 1$, whence $(-1)^m = 1$. Thus $m = 2n$.

Equality (19) takes the form

$$y^2 = 25 \cdot 10^{2m+1} + 281 = 25 \cdot 10^{4n+1} + 281.$$

Since $10^4 \equiv 1 \pmod{101}$, it follows that $y^2 \equiv 250 + 281 \pmod{101}$. Hence $y^2 \equiv 26 \pmod{101}$, whence $\left(\frac{26}{101}\right) = 1$. But $\left(\frac{26}{101}\right) = \left(\frac{-75}{101}\right) = \left(\frac{3}{101}\right) = \left(\frac{101}{3}\right) = \left(\frac{2}{3}\right) = -1$, which is a contradiction.

5. For $a_{14} = 44 \cdots 45444 = x^2$ and $y = 3x/2$ we have the equation:

$$y^2 - 10^k = 2249.$$

If $k = 2m$, $m \geq 3$, we have either

$$y - 10^m = 1 \text{ and } y + 10^m = 2249$$

or

$$y - 10^m = 13 \text{ and } y + 10^m = 173,$$

and none of these systems has solutions.

If $k = 2m + 1$, then $m \geq 2$. With $z = 10^m$ we have the equation:

$$y^2 - 10z^2 = 2249. \tag{23}$$

The initial solutions (a,b) of the equation are $(57,10)$, $(147,44)$, $(153,46)$, hence the solutions with $y>0$, $z>0$ are given by the identities:

$$y+10^m\sqrt{10}=\left(57-10\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{24}$$

$$y+10^m\sqrt{10}=\left(57+10\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{25}$$

$$y+10^m\sqrt{10}=\left(147-44\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{26}$$

$$y+10^m\sqrt{10}=\left(147+44\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{27}$$

$$y+10^m\sqrt{10}=\left(153-46\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{28}$$

$$y+10^m\sqrt{10}=\left(153+46\sqrt{10}\right)\left(19+6\sqrt{10}\right)^t, \tag{29}$$

where $t\in\mathbb{N}$. We get by (24) that $10^m=57b_t-10a_t$, hence $10^m\equiv -a_t \pmod 3$, which yields the contradiction $1\equiv -1 \pmod 3$.

If (27) was true, then $10^m=147b_t+44a_t$. Since $a_t\equiv 1 \pmod 3$ and $10^m\equiv 1 \pmod 3$, the contradiction $1\equiv 44 \pmod 3$ follows.

In the case when (28) holds, we get $10^m=153b_t-46a_t$, whence the contradiction $1\equiv -46 \pmod 3$.

We still have to study three situations.

a) We have by (25) that

$$10^m=57b_t+10a_t. \tag{30}$$

Since $m\geq 2$, it follows that $b_t+2a_t\equiv 0 \pmod 4$. By (4) and (5) we have $6t(-1)^{t-1}+2(-1)^t\equiv 0 \pmod 4$. Therefore $3t-1\equiv 0 \pmod 2$, and we get that t is odd. It then follows that $19\mid a_t$, and by (30) we deduce the contradiction $19\mid 10^m$.

b) It follows by (26) that

$$10^m=147b_t-44a_t. \tag{31}$$

Just as in the case a), by considering congruences $\pmod 4$, we get that t is even.

Also by (31) we have $2b_t+a_t\equiv 0 \pmod 5$, whence by (4) and (5) we get $t\equiv 3 \pmod 5$. Then $(t+2)/5$ is an even natural number. The relation (26) takes the form

$$\begin{aligned} y+10^m\sqrt{10} &= \left(147-44\sqrt{10}\right)\left(19+6\sqrt{10}\right)^{t+2}\left(19-6\sqrt{10}\right)^2 \\ &\equiv \left(147-44\sqrt{10}\right)\left(721-228\sqrt{10}\right) \pmod{281} \\ &\equiv \left(147-44\sqrt{10}\right)\left(-122+53\sqrt{10}\right) \pmod{281}. \end{aligned}$$

It then follows that $10^m\equiv 13159 \pmod{281}\equiv -48 \pmod{281}$, hence $\left(\frac{10^m}{281}\right)=\left(\frac{-48}{281}\right)$. One directly gets a contradiction, observing that $\left(\frac{10}{281}\right)=\left(\frac{-1}{281}\right)=\left(\frac{16}{281}\right)=1$ and $\left(\frac{3}{281}\right)=-1$.

c) By (29) we have the equation:

$$10^m=153b_t+46a_t. \tag{32}$$

For $m = 2$, we get the number 102249 which is not a square. Hence $m \geq 3$.

For $m \geq 3$, we have $b_t - 2a_t \equiv 0 \pmod 8$, and then $t = 4h + 1$. Also by (32) we have $3b_t + a_t \equiv 0 \pmod 5$, whence $t \equiv 2 \pmod 5$. Therefore $(t-2)/5$ is an odd natural number, which in turn implies that $\left(19 + 6\sqrt{10}\right)^{(t-2)/5} \equiv -1 \pmod{281}$. By (29) we have the following relations:

$$\begin{aligned} y + 10^m\sqrt{10} &= \left(153 + 46\sqrt{10}\right)\left(19 + 6\sqrt{10}\right)^{t-2}\left(19 + 6\sqrt{10}\right)^2 \\ &\equiv -\left(153 + 46\sqrt{10}\right)\left(-122 - 53\sqrt{10}\right) \pmod{281}. \end{aligned}$$

Then $10^m \equiv 13721 \equiv -48 \pmod{281}$, that is, the contradiction from *b)*.

6. For $a_{19} = 88\cdots81 = x^2$, denoting $y = 3x$ we get the equation:

$$y^2 = 8 \cdot 10^k - 71.$$

If $k = 2m$, then $m \geq 3$. We denote $z = 2 \cdot 10^m$ and get the identity:

$$y^2 - 2z^2 = -71.$$

It then follows for $y, z > 0$ that either

$$y + z\sqrt{2} = \left(1 + 6\sqrt{2}\right)\left(3 + 2\sqrt{2}\right)^t, \tag{33}$$

or

$$y + z\sqrt{2} = \left(-1 + 6\sqrt{2}\right)\left(3 + 2\sqrt{2}\right)^t. \tag{34}$$

We set $\left(3 + 2\sqrt{2}\right)^t = c_t + d_t\sqrt{2}$. For $t \geq 1$ we then have the equalities:

$$c_t = 3^t + C_t^2 \cdot 3^{t-2} \cdot 2^2 \cdot 2 + \cdots, \tag{35}$$

$$d_t = 2t \cdot 3^{t-1} + C_t^3 \cdot 3^{t-3} \cdot 2^4 + \cdots \tag{36}$$

a) We have by (33) that $d_t + 6c_t \equiv 0 \pmod 8$. Then $2t + 18 \equiv 0 \pmod 8$, hence $t = 4h + 3$, whence $d_t \equiv 2^{t+(t-1)/2} \pmod 3$. We have $z = d_t + 6c_t$. It follows that $2 \cdot 10^m \equiv d_t \pmod 3$, hence $2 \cdot 10^m \equiv 2^{6h+4} \pmod 3$, whence $10^m \equiv 2^{6h+3} \pmod 3$, consequently,

$$\left(\frac{10^m}{3}\right) = \left(\frac{2^{6h+3}}{3}\right) = \left(\frac{2^{3k+1}}{3}\right)^2 \cdot \left(\frac{2}{3}\right) = -1.$$

Since $\left(\frac{10^m}{3}\right) = \left(\frac{1}{3}\right)$, a contradiction follows.

b) For $k = 2m$, we consider the equality (34) and we have $2 \cdot 10^m = -d_t + 6c_t$, hence $d_t \equiv 6c_t \pmod 8$. It follows that $2t \equiv 18 \pmod 8$, that is, $t = 4h + 1$. We then have $2 \cdot 10^m \equiv -d_t \equiv -2^{4h+1} \cdot 2^{2h} \pmod 3$. Hence $10^m \equiv -(2^{3h})^2 \pmod 3$ and $\left(\frac{10^m}{3}\right) = \left(\frac{-1}{3}\right) = -1 \neq 1 = \left(\frac{10^m}{3}\right)$.

For $k = 2m + 1$ we have $m \geq 2$. Denoting $z = 4 \cdot 10^m$, we get the equation:

$$y^2 - 5z^2 = -71.$$

For $y, z > 0$ we have either

$$y + z\sqrt{5} = \left(3 + 4\sqrt{5}\right)\left(9 + 4\sqrt{5}\right)^t, \tag{37}$$

or

$$y + z\sqrt{5} = \left(-3 + 4\sqrt{5}\right)\left(9 + 4\sqrt{5}\right)^t, \tag{38}$$

where t is a natural number.

We put $\left(9 + 4\sqrt{5}\right)^t = e_t + f_t\sqrt{5}$ and then

$$e_t = 9^t + C_t^2 \cdot 9^{t-2} \cdot 4^2 \cdot 5 + \cdots, \tag{39}$$

$$f_t = 4t \cdot 9^{t-1} + C_t^3 \cdot 9^{t-3} \cdot 4^3 \cdot 5 + \cdots \tag{40}$$

It follows by (37) and (38) that $z = 4 \cdot 10^m = 4e_t \pm 3f_t$, hence $4e_t \pm 3f_t \equiv 0 \pmod 8$. By (39) and (40) we get $4 \pm 4t \equiv 0 \pmod 8$, whence $t = 2h + 1$.

By $4 \cdot 10^m = 4e_t \pm 3f_t$ we infer $4 \cdot 10^m \equiv e_t \pmod 3$. Since t is odd, we have $e_t \equiv 0 \pmod 3$, and the contradiction $4 \cdot 10^m \equiv 0 \pmod 3$.

Remarks. It would be interesting to solve the similar problem involving numbers written with respect to some basis $b \geq 2$.

It might be more difficult to consider the same problem imposing the condition all-but-one-equal-digits to higher powers, instead of squares.

Abstract

We give a polynomial time algorithm for computing the Igusa local zeta function $Z(s,f)$ attached to a polynomial $f(x) \in \mathbb{Z}[x]$, in one variable, with splitting field $\mathbb{Q}$, and a prime number p. We also propose a new class of linear feedback shift registers based on the computation of Igusa's local zeta function.

1. Introduction

Let $f(x) \in \mathbb{Z}[x]$, $x = (x_1, \cdots, x_n)$ be a non-constant polynomial, and p a fixed prime number. We put $N_m(f,p) = N_m(f)$ for the number of solutions of the congruence $f(x) \equiv 0 \mod p^m$ in $(\mathbb{Z}/p^m\mathbb{Z})^n$, $m \geqq 1$, and $H(t,f)$ for the Poincaré series

$$H(t,f) = \sum_{m=0}^{\infty} N_m(f)(p^{-n}t)^m,$$

with $t \in \mathbb{C}$, $\mid t \mid < 1$, and $N_0(f) = 1$. This paper is dedicated to the computation of the sequence $\{N_m(f)\}_{m \geq 0}$ when f is an univariate polynomial with splitting field $\mathbb{Q}$.

Igusa showed that the Poincaré series $H(t,f)$ admits a meromorphic continuation to the complex plane as a rational function of t [14], [15]. In this paper we make a first step towards the solution of the following problem: given a polynomial $f(x)$ as above, how difficult is to compute the meromorphic continuation of the Poincaré series $H(t,f)$?

The computation of the Poincaré series $H(t,f)$ is equivalent to the computation of Igusa's local zeta function $Z(s,f)$, attached to f and p, defined as follows. We denote by $\mathbb{Q}_p$ the field of $p-$adic numbers, and by $\mathbb{Z}_p$ the ring of $p-$adic integers. For $x \in \mathbb{Q}_p$, $v_p(x)$ denotes

the $p-$adic order of x, and $|x|_p = p^{-v_p(x)}$ its absolute value. The Igusa local zeta function associated to f and p is defined as follows:

$$Z(s,f) = \int_{\mathbb{Z}_p^n} |f(x)|_p^s \mid dx \mid, \qquad s \in \mathbb{C},$$

where $\mathrm{Re}(s) > 0$, and $\mid dx \mid$ denotes the Haar measure on $\mathbb{Q}_p^n$ so normalized that $\mathbb{Z}_p^n$ has measure 1. The following relation between $Z(s,f)$ and $H(t,f)$ holds (see [14], theorem 8.2.2):

$$H(t,f) = \frac{1 - tZ(s,f)}{1-t}, \ t = p^{-s}.$$

Thus, the rationality of $Z(s,f)$ implies the rationality of the Poincaré series $H(t,f)$, and the computation of $H(t,f)$ is equivalent to the computation of$Z(s,f)$. Igusa [14, theorem 8.2.1] showed that the local zeta function $Z(s,f)$ admits a meromorphic continuation to the complex plane as a rational function of p^{-s}.

The first result of this paper is a polynomial time algorithm for computing the local zeta function $Z(s,f)$ attached to a polynomial $f(x) \in \mathbb{Z}[x]$, in one variable, with splitting field $\mathbb{Q}$, and a prime number p. We also give an explicit estimate for its complexity (see algorithm Compute_$Z(s,f)$ in section 2, and theorem 7.1).

Many authors have found explicit formulas for $Z(s,f)$, or $H(f,t)$, for several classes of polynomials, among them [6], [7], [10], [11], [[16] and the references therein], [19], [24], [25]. In all these works the computation of $Z(s,f)$, or $H(f,t)$, is reduced to the computation of other problems, as the computation of the number of solutions of polynomial equations with coefficients in a finite field. Currently, there is no polynomial time algorithm solving this problem [23], [22]. Moreover, none of the above mentioned works include complexity estimates for the computation of Igusa's local zeta functions.

Of particular importance is Denef's explicit formula for $Z(s,f)$, when f satisfies some generic conditions [6]. This formula involves the numerical data associated to a resolution of singularities of the divisor $f = 0$, and the number of rational points of certain non-singular varieties over finite fields. Thus the computation of $Z(s,f)$, for a generic polynomial f, is reduced to the computation of the numerical data associated to a resolution of singularities of the divisor $f = 0$, and the number of solutions of non-singular polynomials over finite fields. Currently, it is unknown if these problems can be solved in polynomial time on a Turing machine. However, during the last few years important achievements have been obtained in the computation of resolution of singularities of polynomials [2], [3], [4], [21].

The computation of the Igusa local zeta function for an arbitrary polynomial seems to be an intractable problem on a Turing machine. For example, for $p = 2$, the computation of the number of solutions of a polynomial equation with coefficients in $\mathbb{Z}/2\mathbb{Z}$ is an $\mathbf{NP}-$complete problem on a Turing Machine [9, page 251, problem AN9]. Then in the case of $2-$adic numbers, the computation of the Igusa local zeta function is an $\mathbf{NP}-$complete problem.

Recently, Anshel and Goldfeld have shown the existence of a strong connection between the computation of zeta functions and cryptography [1]. Indeed, they proposed a new class of candidates for one-way functions based on global zeta functions. A one-way function is a function F such that for each x in the domain of F, it is easy to compute $F(x)$; but for essentially all y in the range of F, it is an intractable problem to find an x such that $y = F(x)$. These functions play a central role, from a practical and theoretical point of view, in modern cryptography. Currently, there is no guarantee that one-way functions exist even

if $\mathbf{P} \neq \mathbf{NP}$. Most of the present candidates for one-way functions are constructed on the intractability of problems like integer factorization and discrete logarithms [12]. Recently, P. Shor has introduced a new approach to attack these problems [20]. Indeed, Shor have shown that on a quantum computer the integer factorization and discrete logarithm problems can be computed in polynomial time.

We set

$$\mathcal{H} = \{H(t,f) \mid f(x) \in \mathbb{Z}[x], \text{ in one variable, with splitting field } \mathbb{Q}\},$$

and $N^{\infty}(\mathbb{Z})$ for the set of finite sequences of integers. For each positive integer u and a prime number p, we define

$$\begin{array}{rccc} F_{u,p}: & \mathcal{H} & \rightarrow & \mathbb{N}^{\infty}(\mathbb{Z}) \\ & H(t,f) & \rightarrow & \{N_0(f,p), N_1(f,p), \cdots, N_u(f,p)\}. \end{array}$$

Our second result asserts that $F_{u,p}(H(t,f))$ can be computed in polynomial time, for every $H(t,f)$ in $\mathcal{H}$ (see theorem 8.1). It seems interesting to study the complexity on a Turing machine of the following problem: given a list of positive integers $\{a_0, a_1, \cdots, a_u\}$, how difficult is it to determine whether or not there exists a Poincaré series $H(t,f) = \sum_{m=0}^{\infty} N_m(f)(p^{-1}t)^m$, such that $a_i = N_i(f)$, $i = 1, \cdots, u$?

Currently, the author does not have any result about the complexity of the above problem, however the mappings $F_{u,p}$ can be considered as new class of stream ciphers (see section 8).

2. The Algorithm Compute_$Z(s,f)$

In this section we present a polynomial time algorithm, Compute_$Z(s,f)$, that solves the following problem: given a polynomial $f(x) \in \mathbb{Z}[x]$, in one variable, whose splitting field is $\mathbb{Q}$, find an explicit expression for the meromorphic continuation of $Z(s,f)$. The algorithm is as follows.

Algorithm Compute_$Z(s,f)$

Input : A polynomial $f(x) \in \mathbb{Z}[x]$, in one variable, whose splitting field is $\mathbb{Q}$.

Output : A rational function of p^{-s} that is the meromorphic continuation of $Z(s,f)$.

(1) Factorize $f(x)$ in $\mathbb{Q}[x]$: $f(x) = \alpha_0 \prod_{i=1}^{r} (x - \alpha_i)^{e_i} \in \mathbb{Q}[x]$.

(2) Compute

$$l_f = \begin{cases} 1 + \max\{v_p(\alpha_i - \alpha_j) \mid i \neq j,\ 1 \leq i,\ j \leq r\}, & \text{if } r \geqq 2; \\ 1, & \text{if } \quad r = 1. \end{cases}$$

(3) Compute the $p-$adic expansions of the numbers α_i, $i = 1, 2, \cdots, r$ modulo p^{l_f+1}.

(4) Compute the tree $T(f, l_f)$ associated to $f(x)$ and p (for the definition of $T(f, l_f)$ see (4.2)).

(5) Compute the generating function $G(s, T(f, l_f), p)$ attached to $T(f, l_f)$ (for the definition of $G(s, T(f, l_f), p)$ see (5.1)).

(6) Return $Z(s,f) = G(s, T(f, l_f), p)$.

(7) End

In section 6, we shall give a proof of the correctness and a complexity estimate for the algorithm Compute_$Z(s,f)$. The first step in our algorithm is accomplished by means of the

factoring algorithm by A.K. Lenstra, H. Lenstra and L. Lovász [17]. If d_f denotes the degree of $f(x)=\sum_i a_i x^i$, and

$$\|f\|=\sqrt{\sum_i a_i^2},$$

then the mentioned factoring algorithm needs $O\left(d_f^6+d_f^9(\log\|f\|)\right)$ arithmetic operations, and the integers on which these operations are performed each have a binary length

$$O\left(d_f^3+d_f^2(\log\|f\|)\right)$$

[17, theorem 3.6].

The steps 2, 3, 4, 5 reduce in polynomial time the computation of $Z(s,f)$ to the computation of a factorization of $f(x)$ over $\mathbb{Q}$. This reduction is accomplished by constructing a weighted tree from the $p-$adic expansion of the roots of $f(x)$ modulo a certain power of p (see section 4), and then associating a generating function to this tree (see section 5). Finally, we shall prove that the generating function constructed in this way coincides with the local zeta function of $f(x)$ (see section 5).

3. p-adic Stationary Phase Formula

Our main tool in the effective computing of Igusa's local zeta function of a polynomial in one variable will be the $p-$adic stationary phase formula, abbreviated SPF [16]. This formula is a recursive procedure for computing local zeta functions. By using this procedure it is possible to compute the local zeta functions for many classes of polynomials [[16] and the references therein], [19], [24], [25], [26].

Given a polynomial $f(x)\in\mathbb{Z}_p[x]\setminus p\mathbb{Z}_p[x]$, we denote by $\overline{f(x)}$ its reduction modulo $p\mathbb{Z}_p$, i.e., the polynomial obtained by reducing the coefficients of $f(x)$ modulo $p\mathbb{Z}_p$. We define for each $x_0\in\mathbb{Z}_p$,

$$f_{x_0}(x)=p^{-e_{x_0}}f(x_0+px),$$

where e_{x_0} is the minimum order of p in the coefficients of $f(x_0+px)$. Thus $f_{x_0}(x)\in\mathbb{Z}_p[x]\setminus p\mathbb{Z}_p[x]$. We shall call the polynomial $f_{x_0}(x)$ the *dilatation* of $f(x)$ at x_0. We also define

$$\nu(\overline{f})=\mathrm{Card}\{\overline{z}\in\mathbb{F}_p\mid\overline{f}(\overline{z})\neq 0\},$$

$$\delta(\overline{f})=\mathrm{Card}\{\overline{z}\in\mathbb{F}_p\mid\overline{z}\text{ is a simple root of }\overline{f}(\overline{z})=0\}.$$

We shall use $\{0,1,\cdots,p-1\}\subseteq\mathbb{Z}_p$ as a set of representatives of the elements of $\mathbb{F}_p=\mathbb{Z}/p\mathbb{Z}=\{\overline{0},\overline{1},\cdots,\overline{p-1}\}$. Let $S=S(f)$ denote the subset of $\{0,1,\cdots,p-1\}\subseteq\mathbb{Z}_p$ which is mapped bijectively by the canonical homomorphism $\mathbb{Z}_p\to\mathbb{Z}_p/p\mathbb{Z}_p$ to the set of roots of $\overline{f}(\overline{z})=0$ with multiplicity greater than or equal to two.

With all the above notation we are able to state the $p-$adic stationary phase formula for polynomials in one variable.

Proposition 3.1 ([14, theorem 10.2.1]). *Let $f(x)\in\mathbb{Z}_p[x]\setminus p\mathbb{Z}_p[x]$ be a non-constant polynomial. Then*

$$Z(s,f)=p^{-1}\nu(\overline{f})+\delta(\overline{f})\frac{(1-p^{-1})p^{-1-s}}{(1-p^{-1-s})}+\sum_{\xi\in S}p^{-1-e_\xi s}\int\limits_{\mathbb{Z}_p}\mid f_\xi(x)\mid_p^s dx.$$

The following example illustrates the use of the $p-$adic stationary phase formula, and also the basic aspects of our algorithm for computing $Z(s,f)$.

3.1. **Example.** Let $f(x)=(x-\alpha_1)(x-\alpha_2)^3(x-\alpha_3)(x-\alpha_4)^2(x-\alpha_5)$ be a polynomial such that α_1, α_2 , α_3, α_4 , α_5 are integers having the following $p-$adic expansions:

$$\alpha_1 = a+dp+kp^2,$$

$$\alpha_2 = a+dp+lp^2,$$

$$\alpha_3 = b+gp+mp^2,$$

$$\alpha_4 = c+hp+np^2,$$

$$\alpha_5 = c+hp+rp^2,$$

where the p-adic digits a, b, c, d, g, h, l, m, n, r belong to $\{0,1,\cdots,p-1\}$. We assume the p-adic digits to be different by pairs. The local zeta function $Z(s,f)$ will be computed by using SPF iteratively.

By applying SPF with $\overline{f(x)}=(x-\overline{a})^4(x-\overline{b})(x-\overline{c})^3$, $\nu(\overline{f})=p-3$, $\delta(\overline{f})=1, S=\{a,c\}$, $f_a(x)=p^{-4}f(a+px)$, and $f_c(x)=p^{-3}f(c+px)$, we obtain that

$$\begin{aligned} Z(s,f) &= p^{-1}(p-3)+\frac{(1-p^{-1})p^{-1-s}}{1-p^{-1-s}}+p^{-1-4s}\int_{\mathbb{Z}_p}|f_a(x)|_p^s \mid dx \mid \\ &\quad +p^{-1-3s}\int_{\mathbb{Z}_p}|f_c(x)|_p^s \mid dx \mid . \end{aligned} \tag{3.1}$$

We apply SPF to the integrals involving $f_a(x)$ and $f_c(x)$ in (3.1). First, we consider the integral corresponding to $f_a(x)$. Since $\overline{f_a(x)}=(x-\overline{d})^4(\overline{a}-\overline{b})(\overline{a}-\overline{c})^3$, $S=\{d\}$, $f_{a,d}(x)=p^{-4}f_a(d+px)$, $\nu(\overline{f_a})=p-1$, and $\delta(\overline{f_a})=0$, it follows from (3.1) using SPF that

$$\begin{aligned} Z(s,f) &= p^{-1}(p-3)+\frac{(1-p^{-1})p^{-1-s}}{1-p^{-1-s}}+p^{-1}(p-1)p^{-1-4s} \\ &\quad +p^{-2-8s}\int_{\mathbb{Z}_p}|f_{a,d}(x)|_p^s \mid dx \mid +p^{-1-3s}\int_{\mathbb{Z}_p}|f_c(x)|_p^s \mid dx \mid . \end{aligned} \tag{3.2}$$

Now, we apply SPF to the integral involving $f_c(x)$ in (3.2). Since $\overline{f_c(x)}=(\overline{c}-\overline{a})^4(\overline{c}-\overline{b})(x-\overline{h})^3$, $S=\{h\}$, $f_{c,h}(x)=p^{-3}f_c(h+px)$, $\nu(\overline{f_c})=p-1$, and $\delta(\overline{f_c})=0$, it follows from (3.2) using SPF that

$$\begin{aligned} Z(s,f) &= p^{-1}(p-3)+\frac{(1-p^{-1})p^{-1-s}}{1-p^{-1-s}}+p^{-1}(p-1)p^{-1-4s} \\ &\quad +p^{-2-8s}\int_{\mathbb{Z}_p}|f_{a,d}(x)|_p^s \mid dx \mid +p^{-1}(p-1)p^{-1-3s} \\ &\quad +p^{-2-6s}\int_{\mathbb{Z}_p}|f_{c,h}(x)|_p^s \mid dx \mid . \end{aligned} \tag{3.3}$$

By applying SPF to the integral involving $f_{a,d}(x)$ in (3.3), with $\overline{f_{a,d}(x)}=(x-\overline{k})(x-\overline{l})^3(\overline{d}-\overline{b})(\overline{d}-\overline{c})^3$, $S=\{k,l\}$, $f_{a,d,k}(x)=p^{-1}f_{a,d}(k+px)$, $|f_{a,d,k}(x)|_p^s=|x|_p^s$, $f_{a,d,l}(x)=p^{-3}f_{a,d}(l+px)$, $|f_{a,d,l}(x)|_p^s=|x|_p^{3s}$, $\nu(\overline{f_{a,d}})=p-2$, and $\delta(\overline{f_{a,d}})=1$, we obtain that

$$\begin{aligned} Z(s,f) &= p^{-1}(p-3)+\frac{(1-p^{-1})p^{-1-s}}{1-p^{-1-s}}+p^{-1}(p-1)p^{-1-4s} \\ &+p^{-1}(p-1)p^{-1-3s}+p^{-1}(p-2)p^{-2-8s}+\frac{(1-p^{-1})p^{-3-9s}}{1-p^{-1-s}} \\ &+\frac{(1-p^{-1})p^{-3-11s}}{1-p^{-1-3s}}+p^{-2-6s}\int_{\mathbb{Z}_p}|f_{c,h}(x)|_p^s \mid dx \mid . \end{aligned} \tag{3.4}$$

Finally, by applying SPF to the integral involving $f_{c,h}(x)$ in (3.4), we obtain that

$$\begin{aligned} Z(s,f) &= p^{-1}(p-3)+\frac{(1-p^{-1})p^{-1-s}}{1-p^{-1-s}}+p^{-1}(p-1)p^{-1-4s} \\ &+p^{-1}(p-1)p^{-1-3s}+p^{-1}(p-2)p^{-2-8s}+\frac{(1-p^{-1})p^{-3-9s}}{1-p^{-1-s}} \\ &+\frac{(1-p^{-1})p^{-3-11s}}{1-p^{-1-3s}}+p^{-1}(p-2)p^{-2-6s}+\frac{(1-p^{-1})p^{-3-7s}}{1-p^{-1-s}} \\ &+\frac{(1-p^{-1})p^{-3-8s}}{1-p^{-1-2s}}. \end{aligned} \tag{3.5}$$

Remark 3.1. *If $\alpha=\frac{a}{b}\in\mathbb{Q}$, and $v_p(\alpha)<0$, then*

$$\mid x-\alpha\mid_p = \mid \alpha\mid_p, \text{ for every } x\in\mathbb{Z}_p. \tag{3.6}$$

On the other hand, a polynomial of the form

$$f(x)=\alpha_0\prod_{i=1}^{r}(x-\alpha_i)^{e_i}\in\mathbb{Q}[x],$$

can be decomposed as $f(x)=\alpha_0 f_-(x)f_+(x)$, where

$$f_-(x)=\prod_{\{\alpha_i\mid v_p(\alpha_i)<0\}}(x-\alpha_i)^{e_i}, \text{ and } f_+(x)=\prod_{\{\alpha_i\mid v_p(\alpha_i)\geqq 0\}}(x-\alpha_i)^{e_i}. \tag{3.7}$$

From (3.6) and (3.7) follow that

$$Z(s,f)=\mid \alpha_0\prod_{\{\alpha_i\mid v_p(\alpha_i)<0\}}{\alpha_i}^{e_i}\mid_p^s Z(s,f_+).$$

Thus, from a computational point of view, we may assume without loss of generality that all roots of $f(x)$ are $p-$adic integers.

4. Trees and p-adic Numbers

The tree $U=U(p)$ of residue classes modulo powers of a given prime number p is defined as follows. Consider the diagram

$$\{0\}=\mathbb{Z}/p^0\mathbb{Z}\underleftarrow{\phi_1}\ \mathbb{Z}/p^1\mathbb{Z}\ \underleftarrow{\phi_2}\ \mathbb{Z}/p^2\mathbb{Z}\ \underleftarrow{\phi_3}\cdots$$

where ϕ_l the are the natural homomorphisms. The vertices of U are the elements of $\mathbb{Z}/p^l\mathbb{Z}$, for $l=0,1,2,\cdots$, and the directed edges are $u\to v$ where $u\in\mathbb{Z}/p^l\mathbb{Z}$ and $\phi_l(u)=v$, for some $l>0$. Thus U is a rooted tree with root $\{0\}$. Exactly one directed edge emanates from

each vertex of U; except from the vertex $\{0\}$, from which no edge emanates. In addition, every vertex is the end point of exactly p directed edges.

Given two vertices u, v the notation $u > v$ will mean that there is a sequence of vertices and edges of the form

$$u \to u^{(1)} \to \cdots \to u^{(m)} = v.$$

The notation $u \geqq v$ will mean that $u = v$ or $u > v$. The *level* $l(u)$ of a vertex u is m if $u \in \mathbb{Z}/p^m\mathbb{Z}$. The *valence* $Val(u)$ of a vertex u is defined as the number of directed edges whose end point is u.

A subtree, or simply a tree, is defined as a nonempty subset T of vertices of U, such that when $u \in T$ and $u > v$, then $v \in T$. Thus T together with the directed edges $u \to v$, where $u, v \in T$, is again a tree with root $\{0\}$.

A tree T is named a *weighted tree*, if there exists a weight function $W : T \to \mathbb{N}$. The value $W(u)$ is called the weight of vertex u.

If $x \in \mathbb{Z}_p$, and x_l denotes its residue class modulo p^l, then every vertex of U is of the type x_l with $l \in \mathbb{N}$.

A *stalk* is defined as a tree K having at most one vertex at each level. Thus a stalk is either finite, of the type

$$\{0\} \longleftarrow u^{(1)} \longleftarrow \cdots \longleftarrow u^{(l)},$$

or infinite, of the type

$$\{0\} \longleftarrow u^{(1)} \longleftarrow \cdots.$$

Clearly a finite stalk may be written as

$$\{0\} \longleftarrow x_1 \longleftarrow \cdots \longleftarrow x_l,$$

with $x \in \mathbb{Z}$, and infinite stalks as

$$\{0\} \longleftarrow x_1 \longleftarrow x_2 \longleftarrow \cdots,$$

with $x \in \mathbb{Z}_p$. Thus there is a $1-1$ correspondence between infinite stalks and $p-$adic integers.

4.1. **Tree Attached to a Polynomial.** Let

$$f(x) = \alpha_0 \prod_{i=1}^{r} (x - \alpha_i)^{e_i} \in \mathbb{Q}[x] \tag{4.1}$$

be a non-constant polynomial, in one variable, of degree d_f, such that $v_p(\alpha_i) \geqslant 0$, $i = 1, 2, \cdots, r$. We associate to $f(x)$ and a prime number p the integer

$$l_f = \begin{cases} 1 + \max\{v_p(\alpha_i - \alpha_j) \mid i \neq j,\, 1 \leq i,\, j \leq r\}, & \text{if } \ r \geqq 2; \\ 1, & \text{if } \ r = 1. \end{cases}$$

We set

$$\alpha_i = a_{0,i} + a_{1,i}\, p + \cdots + a_{j,i}\, p^j + \cdots + a_{l_f,i}\, p^{l_f} \bmod p^{l_f+1},$$

$a_{j,i} \in \{0, 1, \cdots, p-1\}$, $j = 0, 1, \cdots, l_f$, $i = 1, 2, \cdots, r$, for the $p-$adic expansion modulo p^{l_f+1} of α_i. We attach a weighted tree $T(f,\, l_f)$ to f as follows:

$$T(f, l_f, p) = T(f, l_f) = \bigcup_{i=1}^{r} K(\alpha_i, l_f), \tag{4.2}$$

where $K(\alpha_i, l_f)$ denotes the stalk corresponding to the $p-$adic expansion of α_i modulo p^{l_f+1}. Thus $T(f,\, l_f)$ is a rooted tree. We introduce a weight function on $T(f,\, l_f)$, by defining the weight of a vertex u of level m as

$$W(u) = \begin{cases} \sum\limits_{\{i|\alpha_i \equiv u \bmod p^m\}} e_i, & \text{if } m \geqq 1; \\ 0, & \text{if } m = 0. \end{cases} \tag{4.3}$$

Given a vertex $u \in T(f, l_f)$, we define the stalk generated by u to be

$$B_u = \{v \in T(f, l_f) \mid u \geqq v\}.$$

We associate a weight $W^*(B_u)$ to B_u as follows:

$$W^*(B_u) = \sum_{v \in B_u} W(v). \tag{4.4}$$

4.2. **Computation of Trees Attached to Polynomials.** Our next step is to show that a tree $T(f, l_f)$ attached to a polynomial $f(x)$, of type (4.1), can be computed in polynomial time. There are well known programming techniques to construct and manipulate trees and forests (see e.g. [8, Volume 1]), for this reason, we shall focus on showing that such computations can be carry out in polynomial time, and set aside the implementation details of a particular algorithm for this task. We shall include in the computation of $T(f, l_f)$, the computation of the weights of the stalks generated by its vertices; because all these data will be used in the computation of the local zeta function of f.

Proposition 4.1. *The computation of a tree $T(f, l_f)$ attached to a polynomial $f(x)$, of type (4.1), from the $p-$adic expansions modulo p^{l_f+1} of its roots*

$$\alpha_i = a_{0,i} + a_{1,i}\, p + \cdots + a_{l_f,i} p^{l_f} \ \ mod\ p^{l_f+1}$$

and multiplicities e_i, $i = 1, 2, \cdots, r$, involves $O(l_f^2\, d_f^3)$ arithmetic operations on integers with binary length

$$O(\max\{\log p, \log(l_f d_f)\}).$$

Proof. We assume that $T(f, l_f)$ is finite set of the form

$$T = \{\text{Level}_0, \cdots, \text{Level}_j, \cdots, \text{Level}_{l_f+1}\}, \tag{4.5}$$

where Level_j represents the set of all vertices with level j. Each Level_j is a set of the form

$$Level_j = \{u_{j,1}, \cdots, u_{j,i}, \cdots, u_{j,m_j}\},$$

and each $u_{j,i}$ is a weighted vertex for every $i = 1, \cdots, m_j$. A weighted vertex $u_{j,i}$ is a set of the form

$$u_{j,i} = \{\, W(u_{j,i}),\, Val(u_{j,i}), W^*(B_{u_{j,i}})\},$$

where $W(u_{j,i})$ is the weight of $u_{j,i}$, $Val(u_{j,i})$ is its valence, and $W^*(B_{ui})$ is the weight of stalk $B_{u_{j,i}}$. The weight of the stalk generated by $u_{j,i}$ can be written as

$$W^*(B_{u_{j,i}}) = \sum_{v \in B_{u_{j,i}}} W(v).$$

For the computation of a vertex $u_{j,i}$ of level j, we proceed as follows. We put $I = \{1, 2, \cdots, r\}$, and

$$M_j = \{\alpha_i \bmod p^j \mid i \in I\}.$$

For each $0 \leq j \leq l_f + 1$, we compute a partition of I of type

$$I = \bigcup_{i=1}^{l_j} I_{j,i}, \tag{4.6}$$

such that

$$\alpha_t \bmod p^j = \alpha_s \bmod p^j,$$

for every $t, s \in I_{j,i}$. Each subset $I_{j,i}$ corresponds to a vertex $u_{j,i}$ of level j. This computation requires $O(l_f r^2)$ arithmetic operations on integers with binary length $O(\log p)$. Indeed, the cost of computing a "yes or no" answer for the question: $\alpha_t \bmod p^j = \alpha_s \bmod p^j$? is $O(j)$ comparisons of integers with binary length $O(\log p)$. In the worst case, there are r vectors M_j, and the computation of partition (4.6), for a fixed j, involves the comparison of α_t with α_l for $l = t+1, t+2, \cdots, r$. This computation requires $O(jr^2)$ arithmetic operations on integers with binary length $O(\log p)$. Since $j \leqq l_f + 1$, the computation of partition (4.6) requires $O(l_f r^2)$ arithmetic operations on integers with binary length $O(\log p)$.

The weight of the vertex $u_{j,i}$ is given by the expression

$$W(u_{j,i}) = \sum_{k \in I_{j,i}} e_k.$$

Thus the computation of the weight of a vertex requires $O(r)$ additions of integers with binary length $O(\log d_f r)$.

For the computation of the valence of $u_{j,i}$, we proceed as follows. The valence of $u_{j,i}$ can be expressed as

$$Val(u_{j,i}) = \text{Card}\{I_{j+1,l} \mid I_{j+1,l} \subseteq I_{j,i}\},$$

where $I_{j+1,l}$ runs through all possible sets that correspond to the vertices $u_{j+1,l}$, with level $j+1$. Thus the computation of $Val(u_{j,m})$ involves the computation of a "yes or no" answer for the question $I_{j+1,l} \subseteq I_{j,i}$? The computation of a "yes or no" answer involves $O(r)$ comparisons of integers with binary length $O(\log r)$. Therefore the computation of $Val(u_{j,i})$ involves $O(r)$ comparisons and $O(r)$ additions of integers with binary length $O(\log r)$.

For the computation of the weight of $B_{u_{j,i}}$, we observe that $W^*(B_{u_{j,i}})$ is given by the formula

$$W^*(B_{u_{j,i}}) = \sum_{l=0}^{j-1} \sum_{I_{j,i} \subseteq I_{l,k}} W(I_{l,k}),$$

where $W(I_{l,k}) = W(v_{l,k})$, and $v_{l,k}$ is the vertex corresponding to $I_{l,k}$. Thus the computation of $W^*(B_{u_{j,i}})$ involves $O(l_f)$ additions of integers with binary length $O(\log(l_f\ d_f))$, and $O(l_f\ r)$ comparisons of integers with binary length $O(\log r)$.

From the above reasoning follows that the computation of a vertex of a tree $T(f, l_f)$ involves at most $O(l_f\ r^2)$ arithmetic operations (additions and comparisons) on integers with binary length $O(\max\{\log p, \log(\ l_f\ d_f)\})$. Finally, since the number of vertices of $T(f, l_f)$ is at most $O(l_f\ d_f)$, it follows that the computation of a tree of type $T(f, l_f)$ involves $O(l_f^2\ d_f^3)$ arithmetic operations on integers with binary length $O(\max\{\log p, \log(\ l_f\ d_f)\})$. ∎

5. Generating Functions and Trees

In this section we attach to a weighted tree $T(f,l_f)$ and a prime p a generating function $G(s,T(f,l_f),p)\in\mathbb{Q}(p^{-s})$ defined as follows.

We set

$$\mathcal{M}_{T(f,l_f)}=\left\{u\in T(f,l_f)\;\middle|\;\begin{array}{c}W(u)=1,\text{ and there no exists } v\in T(f,l_f)\\ \text{with } W(v)=1,\text{ such that } u>v.\end{array}\right\},$$

and

$$L_u(p^{-s})=\begin{cases}\frac{(1-p^{-1})p^{-l(u)-W^*(B_u)s}}{(1-p^{-1-W(u)s})}, & \text{if } \quad l(u)=1+l_f,\text{ and } W(u)\geqq 2;\\ p^{-1}(p-Val(u))p^{-l(u)-W^*(B_u)s}, & \text{if } \quad 0\leqq l(u)\leqq l_f,\text{ and } W(u)\neq 1;\\ \frac{(1-p^{-1})p^{-l(u)-W^*(B_u)s}}{1-p^{-1-s}}, & \text{if } \quad u\in\mathcal{M}_{T(f,l_f)};\\ 0, & \text{if } \quad W(u)=1,\text{ and } u\notin\mathcal{M}_{T(f,l_f)}.\end{cases}$$

With all the above notation, we define the generating function attached to $T(f,l_f)$ and p as

$$G(s,T(f,l_f),p)=\sum_{u\in T(f,l_f)}L_u(p^{-s}). \tag{5.1}$$

Our next goal is to show that $G(s,T(f,l_f),p)=Z(s,f)$. The proof of this fact requires the following preliminary result.

Proposition 5.1. *The generating function attached to a tree $T(f,l_f)$ and a prime p satisfies*

$$\begin{aligned}G(s,T(f,l_f),p) &= p^{-1}\nu(\overline{f})+\delta(\overline{f})\frac{(1-p^{-1})p^{-1-s}}{(1-p^{-1-s})}\\ &\quad+\sum_{\xi\in S}p^{-1-e_\xi s}G(s,T(f_\xi,l_f-1),p).\end{aligned} \tag{5.2}$$

Proof. Let $A_f=\{u\in T(f,l_f)\mid l(u)=1,\ W(u)=1\}$, and $B_f=\{u\in T(f,l_f)\mid l(u)=1,\ W(u)\geqq 2\}$. We have the following partition for $T(f,l_f)$:

$$T(f,l_f)=\{0\}\bigcup A_f\bigcup\left(\bigcup_{u\in B_f}T_u\right), \tag{5.3}$$

with

$$T_u=\{v\in T(f,l_f)\mid v\geqq u\}.$$

Each T_u is a rooted tree with root $\{u\}$. From partition (5.3) and the definition of $G(s,T(f,l_f),p)$, it follows that

$$\begin{aligned}G(s,T(f,l_f),p) &= p^{-1}\left(p-Val(\{0\})\right)+\mathrm{Card}\{A_f\}\frac{(1-p^{-1})p^{-1-s}}{(1-p^{-1-s})}+\\ &\quad\sum_{u\in B_f}G(s,T_u),\end{aligned} \tag{5.4}$$

with $G(s,T_u)=\sum_{v\in T_u} L_v(p^{-s})$.

Since there exists a bijective correspondence between the roots of $\overline{f}(x)\equiv 0 \bmod p$ and the vertices of $T(f,l_f)$ with level 1,

$$p-Val(\{0\})=\nu(\overline{f}), \text{ and } \ \mathrm{Card}\{A_f\}=\delta(\overline{f}). \tag{5.5}$$

Now, if the vertex u corresponds to the root $\overline{f}(\xi)\equiv 0 \bmod p$, then

$$T_u=\left(\bigcup_{\{\alpha_i|\alpha_i\equiv\xi \bmod p\}} K(\alpha_i,l_f)\right)\setminus\{0\}. \tag{5.6}$$

On the other hand, we have that

$$T(f_\xi,l_f-1)=\bigcup_{\{\alpha_i|\alpha_i\equiv\xi \bmod p\}} K(\frac{\alpha_{i-\xi}}{p},l_f-1). \tag{5.7}$$

Now we remark that the map $\alpha_i\to\frac{\alpha_i-\xi}{p}$ induces a isomorphism between the trees T_u and $T(f_\xi,l_f-1)$, that preserves the weights of the vertices; and thus we may suppose that $T_u=T(f_\xi,l_f-1)$. The level function l_T of $T(f_\xi,l_f-1)$ is related to the level function l_{T_u} of T_u by means of the equality $l_T-l_{T_u}=-1$. In addition, $B_f=S$, where S is the subset of $\{0,1,\cdots,p-1\}\subseteq\mathbb{Z}_p$ whose reduction modulo pZ_p is equal to the set of roots of $\overline{f}(\xi)=0$ with multiplicity greater or equal than two. Therefore, it holds that

$$G(s,T_u)=p^{-1-e_\xi s}G(s,T(f_\xi,l_f-1),p). \tag{5.8}$$

The result follows from (5.4) by the identities (5.5) and (5.8). ∎

Lemma 5.1. *Let p be a fixed prime number and v_p the corresponding $p-$adic valuation, and*

$$f(x)=\alpha_0\prod_{i=1}^{r}(x-\alpha_i)^{e_i}\in\mathbb{Q}[x]\setminus\mathbb{Q},$$

a polynomial such that $v_p(\alpha_i)\geqq 0$, for $i=1,\cdots,r$. Then

$$Z(s,f)=G(s,T(f,l_f),p).$$

Proof. We proceed by induction on l_f.

Case $l_f=1$

If $r=1$ the proof follows immediately, thus we may assume that $r\geqq 2$. Since $l_f=1$, it holds that $v_p(\alpha_i-\alpha_j)=0$, for every i, j, satisfying $i\neq j$, and thus $\overline{\alpha_i}\neq\overline{\alpha_j}$, if $i\neq j$. By applying SPF, we have that

$$Z(s,f)=p^{-1}\nu(\overline{f})+\delta(\overline{f})\frac{(1-p^{-1})p^{-1-s}}{(1-p^{-1-s})}+\sum_{\xi\in S}p^{-1-e_\xi s}\frac{(1-p^{-1})}{(1-p^{-1-e_\xi s})}, \tag{5.9}$$

where each $e_\xi=e_j\geqq 2$, for some j, and $\alpha_j=\xi+p\beta_j$.

On the other hand, $T(f,l_f)$ is a rooted tree with r vertices v_j, satisfying $l(v_j)=1$, and $W(v_j)=e_j$, for $j=1,\cdots,r$. These observations allow one to deduce that $Z(s,f)=G(s,T(f,l_f),p)$.

By induction hypothesis, we may assume that $Z(s,f)=G(s,T(f,l_f),p)$, for every polynomial f satisfying both the hypothesis of the lemma, and the condition $1\leqq l_f\leqq k$, $k\in\mathbb{N}$.

Case $l_f = k+1$, $k \in \mathbb{N}$

Let $f(x)$ be a polynomial satisfying the lemma's hypothesis, and $l_f = k+1$, $k \geqq 1$. By applying SPF, we obtain that

$$Z(s,f) = p^{-1}\nu(\overline{f}) + \delta(\overline{f})\frac{(1-p^{-1})p^{-1-s}}{(1-p^{-1-s})} + \sum_{\xi \in S} p^{-1-e_\xi s}\int \mid f_\xi(x) \mid_p^s dx. \tag{5.10}$$

Now, since $l_{f_\xi} = l_f - 1$, for every $\xi \in S$, it follows from the induction hypothesis applied to each $f_\xi(x)$ in (5.10), that

$$Z(s,f) = p^{-1}\nu(\overline{f}) + \delta(\overline{f})\frac{(1-p^{-1})p^{-1-s}}{(1-p^{-1-s})} + \sum_{\xi \in S} p^{-1-e_\xi s} G(s, T(f_\xi, l_f - 1),\ p). \tag{5.11}$$

Finally, from identity (5.2), and (5.11), we conclude that

$$Z(s,f) = G(s, T(f, l_f), p). \tag{5.12}$$

∎

The following proposition gives a complexity estimate for the computation of $G(s, T(f, l_f), p)$.

Proposition 5.2. *The computation of the generating function*

$$G(s, T(f, l_f), p)$$

from $T(f, l_f)$, involves $O(l_f\ d_f)$ arithmetic operations on integers with binary length $O(\max\{\log p,$ $\log(\ l_f\ d_f)\})$.

Proof. This is a consequence of proposition 4.1, and the definition of generating function. ∎

6. Computation of p-adic Expansions

In this section we estimate the complexity of the steps 2 and 3 in the algorithm Compute_$Z(s,f)$.

Proposition 6.1. *Let*

$$B = \max_{\substack{1 \leq i,\ j \leq r \\ i \neq j}} \{ \mid c_{j,i} \mid, \mid d_{j,i} \mid \quad \mid \alpha_j - \alpha_i = \frac{c_{j,i}}{d_{j,i}},\ c_{j,i},\ d_{j,i} \in \mathbb{Z} \setminus \{0\}\}.$$

The computation of the integer l_f involves $O(d_f^2 \frac{\log B}{\log p})$ arithmetic operations on integers with binary length $O(\max\{\log B, \log p\})$.

Proof. First, we observe that for $c \in \mathbb{Z} \setminus \{0\}$, the computation of $v_p(c)$ involves $O(\frac{\log|c|}{\log p})$ divisions of integers of binary length $O(\max\{\log \mid c \mid, \log p\})$. Thus the computation of $v_p(\frac{c}{d}) = v_p(c) - v_p(d)$, involves $O(\frac{\max\{\log|c|,\ \log|d|\}}{\log p})$ divisions and subtractions of integers with binary length

$$O(\max\{\log \mid c \mid, \log \mid d \mid, \log p\}).$$

From these observations follow that the computation of $v_p(\alpha_j - \alpha_i)$, $i \neq j$, $1 \leq i,\ j \leq r$, involves $O(r^2 \frac{\log B}{\log p})$ arithmetic operations on integers with binary length $O(\max\{\log B, \log p\})$. Finally, the computation of the maximum of the $v_p(\alpha_j - \alpha_i)$, $i \neq j$, $1 \leq i,\ j \leq r$, involves $O(\log r)$ comparisons of integers with binary length $O(\max\{\log B, \log p\})$. Therefore the

computation of the integer l_f involves at most $O(d_f^2 \frac{\log B}{\log p})$ arithmetic operations on integers with binary length $O(\max\{\log B, \log p\})$. ∎

Proposition 6.2. *Let p be a fixed prime and $\gamma = \frac{c}{b} \in \mathbb{Q}$, with $c, b \in \mathbb{Z} \setminus \{0\}$, and $v_p(\gamma) \geqq 0$. The $p-$adic expansion*

$$\gamma = a_0 + a_1\, p + \cdots + a_j p^j + \cdots + a_m p^m,$$

modulo p^{m+1} involves $O(m+\log(\max\{\mid b \mid, p\}))$ arithmetic operations on integers with binary length $O(\max\{\log \mid c \mid, \log \mid b \mid, \log p\})$.

Proof. Let $y \in \{1, \cdots, p-1\}$ be an integer such that $yb \equiv 1 \bmod p$. This integer can be computed by means of the Euclidean algorithm in $O(\log(\max\{\mid b \mid, p\}))$ arithmetic operations involving integers of binary length $O(\max\{\log \mid b \mid, \log p\})$ (cf. [8, Volume 2, section 4.5.2]).

We set $\gamma = \gamma_0 = \frac{c}{b}$, $c_0 = c$, and define $a_0 \equiv yc \bmod p$. With this notation, the $p-$adic digits $a_i, i = 1, \cdots, m$, can be computed recursively as follows:

$$\gamma_i = \frac{\frac{(c_{i-1} - a_{i-1} b)}{p}}{b} = \frac{c_i}{b},$$

$$a_i = y c_i \bmod p.$$

Thus the computation of the $p-$adic expansion of γ needs $O(m + \log(\max\{\mid b \mid, p\}))$ arithmetic operations on integers with binary length

$$O(\max\{\log \mid c \mid,\ \log \mid b \mid,\ \log p\}).$$

∎

Corollary 6.1. *Let p be a fixed prime number and v_p the corresponding $p-$adic valuation, and*

$$f(x) = \alpha_0 \prod_{i=1}^{r} (x - \alpha_i)^{e_i} \in \mathbb{Q}[x],$$

a non-constant polynomial such that $v_p(\alpha_i) \geqq 0$, $i = 1, \cdots, r$. The computation of the $p-$adic expansions modulo p^{l_f+1} of the roots α_i, $i = 1, 2, \cdots, r$, of $f(x)$ involves $O(d_f\ l_f + d_f \log(\max\{B, p\}))$ arithmetic operations on integers with binary length $O(\max\{\log B, \log p\})$.

Proof. The corollary follows directly from the two previous propositions. ∎

7. Computing local zeta functions of polynomials with splitting $\mathbb{Q}$

In this section we prove the correctness of the algorithm Compute_$Z(s, f)$ and estimate its complexity.

Theorem 7.1. *The algorithm Compute_$Z(s, f)$ outputs the meromorphic continuation of the Igusa local zeta function $Z(s, f)$ of a polynomial $f(x) \in \mathbb{Z}[x]$, in one variable, with splitting field $\mathbb{Q}$. The number of arithmetic operations needed by the algorithm is*

$$O\left(d_f^6 + d_f^9 \log(\|f\|) + l_f^2 d_f^3 + d_f^2 \log\left(\max\{B, p\}\right)\right),$$

and the integers on which these operations are performed have a binary length

$$O\left(\max\{\log p,\ \log l_f d_f,\ \log B,\ d_f^3 + d_f^2 \log(\|f\|)\}\right).$$

Proof. By remark (3.1), we may assume without loss of generality that

$$f(x) = \alpha_0 \prod_{i=1}^{r} (x - \alpha_i)^{e_i} \in \mathbb{Q}[x] \setminus \mathbb{Q},$$

with $v_p(\alpha_i) \geqq 0$, $i = 1, \cdots, r$. The correctness of the algorithm follows from lemma 5.1. The complexity estimates are obtained as follows: the number of arithmetic operations needed in the steps 2 (cf. proposition 6.1), 3 (cf. corollary 6.1), 4 (cf. proposition 4.1), 5 (proposition 5.2), and 6 is at most

$$O\left(l_f^2 d_f^3 + d_f^2 \log\left(\max\{B, p\}\right)\right);$$

and these operations are performed on integers whose binary length is at most

$$O\left(\max\{\log p,\ \log l_f d_f, \log B\}\right).$$

The estimates for the whole algorithm follow from the above estimates and those of the factoring algorithm by A. K. Lenstra, H. Lenstra and L. Lovász (see theorem 3.6 of [17]). ∎

8. Stream Ciphers and Poincaré series

There is a natural connection between Poincaré series and stream ciphers. In order to explain this relation, we recall some basic facts about stream ciphers [18]. Let $\mathbb{F}_{p^n}$ be a finite field with p^n elements, with p a prime number. For any integer $r > 0$ and r fixed elements $q_i \in \mathbb{F}_{p^n}$, $i = 1, \cdots, r$ (called taps), a Linear Feedback Shift Register, abbreviated LFSR, of length r consists of r cells with initial contents $\{a_i \in \mathbb{F}_{p^n} \mid i = 1, \cdots, r\}$. For any $n \geqslant r$, if the current state is $(a_{n-1}, \cdots, a_{n-r})$, then a_n is determined by the linear recurrence relation

$$a_n = -\sum_{i=1}^{r} a_{n-i} q_i.$$

The device outputs the rightmost element a_{n-r}, shifts all the cells one unit right, and feeds a_n back to the leftmost cell.

Any configuration of the r cells forms a state of the LSFR. If $q_r \neq 0$, the following polynomial $q(x) \in \mathbb{F}_{p^n}[x]$ of degree r appears in the analysis of LFSRs:

$$q(x) = q_0 + q_1 x + \cdots . + q_r x^r \quad \text{with } q_0 = -1.$$

This polynomial is called the connection polynomial. An infinite sequence $A = \{a_i \in \mathbb{F}_{p^n} \mid i \in \mathbb{N}\}$ has period T if for any $i \geqslant 0$, $a_{i+T} = a_i$. Such a sequence is called periodic. If this is only true for i greater than some index i_0, then the sequence is called eventually periodic. The following facts about an LFSR of length r are well-known [18].

(1) There are only finitely many possible states, and the state with all the cells zero will produce a 0−sequence. The output sequence is eventually periodic and the maximal period is $p^{nr} - 1$.
(2) The Poincaré series $g(x) = \sum_{i=0}^{\infty} a_i x^i$ associated with the output sequence is called the generating function of the sequence. It is a rational function over $\mathbb{F}_{p^n}$ of the form $g(x) = \frac{L(x)}{R(x)}$, with $L(x)$, $R(X) \in \mathbb{F}_{p^n}[x]$, $\deg(R(X)) < r$. The output sequence is strictly periodic if and only if $\deg(L(X)) < \deg(R(X))$.
(3) There is a one-to-one correspondence between LFSRs of length r with $q_r \neq 0$ and rational functions $\frac{L(x)}{R(x)}$ with $\deg(R(X)) = r$ and $\deg(L(X)) < r$.

We set $\mathbb{F}_{p^n}(x)$ for the field of rational functions over $\mathbb{F}_{p^n}$, and $N^{\infty}(\mathbb{F}_{p^n})$ for the set of sequences of the form $\{b_0, \cdots, b_u\}$, $b_i \in \mathbb{F}_{p^n}$, $0 \leq i \leq u$, $u \in \mathbb{N}$. From the above considerations, it is possible to identify an LFSR with a function F_u, $u \in \mathbb{N}$, defined as follows:

$$\begin{array}{rccc} F_u: & \mathbb{F}_{p^n}(x) & \rightarrow & N^{\infty}(\mathbb{F}_{p^n}) \\ & \sum_{i=0}^{\infty} a_i x^i & \rightarrow & \{a_0, \cdots, a_u\}. \end{array} \tag{8.1}$$

We set

$$\mathcal{H} = \{H(t,f) \mid f(x) \in \mathbb{Z}[x], \text{ in one variable, with splitting field } \mathbb{Q}\},$$

and $N^{\infty}(\mathbb{Z})$ for the set of finite sequences of integers. Also, for each $u \in \mathbb{N}$, and a prime number p, we define

$$\begin{array}{rccc} F_{u,p}: & \mathcal{H} & \rightarrow & \mathbb{N}^{\infty}(\mathbb{Z}) \\ & H(t,f) & \rightarrow & \{N_0(f,p), N_1(f,p), \cdots, N_u(f,p)\}. \end{array} \tag{8.2}$$

Thus the mappings $F_{u,p}$ can be seen as LFSRs, or stream ciphers, over $\mathbb{Z}$. If we replace each $N_u(f,p)$ by its binary representation, then the $F_{u,p}$ are LFSRs. For practical purposes it is necessary that $F_{u,p}$ can be computed efficiently, i.e., in polynomial time. With the above notation our second result is the following.

Theorem 8.1. *For every $H(t,f) \in \mathcal{H}$, the computation of $F_{u,p}(H(t,f))$ involves $O(u^2 d_f l_f)$ arithmetic operations, and the integers on which these operations are performed have binary length*

$$O(\max\{\ (l_f + u)\log p,\ \ \log(d_f l_f)\}).$$

The proof of this theorem will be given at the end of this section. This proof requires some preliminary results. We set $t = q^{-s}$, and

$$Z(s,f) = Z(t,f) = \sum_{m=0}^{\infty} c_m(f,p) t^m,$$

with $c_m(f,p) = vol(\{x \in \mathbb{Z}_p \mid v_p(f(x)) = m\})$.

Proposition 8.1. *Let $f(x) \in \mathbb{Z}[x] \setminus \mathbb{Z}$ be a polynomial in one variable and p a prime number. The following formula holds for $N_n(f,p)$:*

$$N_n(f,p) = \begin{cases} 1, & \text{if } \ n = 0; \\ p^n \left(1 - \sum_{j=1}^{n} c_{j-1}(f,p)\right), & \text{if } \ n \geqslant 1. \end{cases} \tag{8.3}$$

Proof. The result follows by comparing the coefficient of t^n of the series

$$\sum_{n=0}^{\infty} \frac{N_n(f,p)}{p^n} t^n \quad \text{and} \quad \sum_{n=0}^{\infty} d_n t^n,$$

in the following equality :

$$H(t,f) = \sum_{n=0}^{\infty} \frac{N_n(f,p)}{p^n} t^n = \frac{1 - t\left(\sum_{m=0}^{\infty} c_m(f,p) t^m\right)}{1-t} = \sum_{n=0}^{\infty} d_n t^n.$$

∎

We associate to each $u \in T(f, l_f)$, and $j \in \mathbb{N}$, a rational integer $a_j(u)$ defined as follows:

$$a_j(u) = \begin{cases} \frac{(p-1)}{p^{l(u)+1+y(u)}}, & \text{if} \quad l(u) = 1 + l_f,\ W(u) \geqq 2,\ j = W^*(B_u) + y(u)W(u), \\ & \qquad \text{for some } y(u) \in \mathbb{N}; \\ \frac{(p-Val(u))}{p^{l(u)+1}}, & \text{if} \quad 0 \leqq l(u) \leqq l_f,\ W(u) \neq 1,\ j = W^*(B_u); \\ \frac{(p-1)}{p^{l(u)+1+y(u)}}, & \text{if} \quad u \in \mathcal{M}_{T(f,l_f)}, j = W^*(B_u) + y(u), \\ & \qquad \text{for some } y(u) \in \mathbb{N}; \\ 0, & \text{if} \quad W(u) = 1, \text{ and } u \notin \mathcal{M}_{T(f,l_f)}; \\ 0, & \qquad \text{in other cases.} \end{cases} \tag{8.4}$$

Proposition 8.2. *Let $f(x) \in \mathbb{Z}[x] \setminus \mathbb{Z}$ be a polynomial in one variable, with splitting field $\mathbb{Q}$, and p a prime number. The following formula holds:*

$$c_j(f, p) = \sum_{u \in T(f,l_f)} a_j(u),\ j \geqq 0. \tag{8.5}$$

Proof. As a consequence of lemma (5.1), we have the following identity:

$$Z(t, f) = \sum_{u \in T(f,l_f)} L_u(t), \tag{8.6}$$

with

$$L_u(t) = \begin{cases} \frac{(p-1)t^{W^*(B_u)}}{p^{l(u)+1}(1-p^{-1}t^{\,W(u)})}, & \text{if} \quad l(u) = 1 + l_f,\ W(u) \geqq 2; \\ \frac{(p-Val(u))}{p^{l(u)+1}} t^{W^*(B_u)}, & \text{if} \quad 0 \leqq l(u) \leqq l_f,\ W(u) \neq 1; \\ \frac{(p-1)t^{W^*(B_u)}}{p^{l(u)+1}(1-p^{-1}t)}, & \text{if} \quad u \in \mathcal{M}_{T(f,l_f)}; \\ 0, & \text{if} \quad W(u) = 1, \text{ and } u \notin \mathcal{M}_{T(f,l_f)}. \end{cases} \tag{8.7}$$

The result follows by comparing the coefficient of t^j in the series $Z(t, f) = \sum_{m=0}^{\infty} c_m(f, p)t^m$, and $Z(t, f) = \sum_{u \in T(f,l_f)} L_u(t)$. ∎

Proposition 8.3. *Let $f(x) \in \mathbb{Z}[x] \setminus \mathbb{Z}$ be a polynomial in one variable, with splitting field $\mathbb{Q}$, and p a prime number.*

1. *The computation of $N_n(f, p)$, $n \geqq 1$, from the $c_{j-1}(f, p)$, $j = 1, \cdots, n$, involves $O(n)$ arithmetic operations on integers with binary length $O(n \log p)$.*
2. *The computation of $c_j(f, p)$, $j \geqq 0$, from $Z(t, f)$, involves $O(d_f l_f)$ arithmetic operations on integers with binary length*

$$O(\max\{(j + l_f) \log p, \log p, \log(d_f l_f)\}).$$

(3) *The computation of any* $N_n(f,p)$, $n \geqq 1$, *from* $Z(t,f)$, *involves* $O(nd_f l_f)$ *arithmetic operations on integers with binary length*

$$O(\max\{(n+l_f)\log p, \log(d_f l_f)\}).$$

Proof. (1) By (8.4) and (8.5), $c_j(f,p) = \frac{v_j}{p^{m_j}}$, $v_j, m_j \in \mathbb{N}$. In addition,

$$c_{j-1}(f,p) = p^{-j+1}N_{j-1}(f,p) - p^{-j}N_j(f,p).$$

Thus $p^n c_{j-1}(f,p) \in \mathbb{N}$, for $j = 1, \cdots, n$, and $m_j \leq n$, for $j = 1, \cdots, n$. From (8.3), it follows that

$$N_n(f,p) = p^n - \sum_{j=1}^{n} p^n c_{j-1}(f,p), \ n \geqslant 1. \tag{8.8}$$

The above formula implies that the computation of $N_n(f,p)$, $n \geqq 1$, from the $c_{j-1}(f,p)$, $j = 1, \cdots, n$, involves $O(n)$ arithmetic operations on integers with binary length $O(n \log p)$.

(2) The computation of $a_j(u)$ from $L_u(t)$ (i.e. from $Z(t,f)$, cf. (8.6)) involves $O(1)$ arithmetic operations (cf. (8.4), (8.7)) on integers of binary length $O(\max\{\log p, \log(d_f l_f)\})$. Indeed, since the numbers $l(u)$, $W^*(B_u)$, $W(u)$, $u \in T(f,l_f)$ are involved in this computation, we know by proposition 4.1 that their binary length is bounded by $O(\max\{\log p, \log(d_f l_f)\})$.

The cost of computing $c_j(f,p)$ from $L_u(t)$, $u \in T(f,l_f)$ (i.e. from $Z(t,f)$) is bounded by the number of vertices of $T(f,l_f)$ multiplied by an upper bound for the cost of computing $a_j(u)$ from $L_u(t)$, for any j, and u (cf. (8.5)). Therefore, from the previous discussion the cost of computing $c_j(f,p)$ from $Z(t,f)$ is bounded by $O(d_f\, l_f)$ arithmetic operations. These arithmetic operations are performed on integers of binary length bounded by $O(\max\{(j+l_f)\log p, \log p, \log(d_f l_f)\})$. Indeed, the binary lengths of the numerator and the denominator of $a_j(u) + a_j(u')$, u, $u' \in T(f,l_f)$ are bounded by $(l_f + 1 + j)\log p$ (cf. (8.4)). Thus, the mentioned arithmetic operations for calculating $c_j(f,p)$ from $L_u(t)$ are performed on integers whose binary length is bounded by $O(\max\{(j+l_f)\log p, \log p, \log(d_f l_f)\})$.

(3) The third part follows the first and second parts by (8.8). ∎

8.1. **Proof of Theorem 8.1.** The theorem follows from proposition 8.3 (3).

Binary BBP-Formulae for Logarithms and Generalized Gaussian-Mersenne Primes

Marc Chamberland
Department of Mathematics and Computer Science
Grinnell College
Grinnell, IA 50112
USA

Abstract:

Constants of the form

$$C = \sum_{k=0}^{\infty} \frac{p(k)}{q(k)b^k}$$

where p and q are integer polynomials, $\deg p < \deg q$, and $p(k)/q(k)$ is non-singular for non-negative k and $b \geq 2$, have special properties. The n^{th} digit (base b) of C may be calculated in (essentially) linear time without computing its preceding digits, and constants of this form are conjectured to be either rational or normal to base b.

This paper constructs such formulae for constants of the form $\log p$ for many primes p. This holds for all Gaussian-Mersenne primes and for a larger class of ``generalized Guassian-Mersenne primes". Finally, connections to Aurifeuillian factorizations are made.

Binary BBP-Formulae for Logarithms and Generalized Gaussian-Mersenne Primes

Abstract

Constants of the form

$$C = \sum_{k=0}^{\infty} \frac{p(k)}{q(k)b^k}$$

where p and q are integer polynomials, $\deg p < \deg q$, and $p(k)/q(k)$ is non-singular for non-negative k and $b \geq 2$, have special properties. The n^{th} digit (base b) of C may be calculated in (essentially) linear time without computing its preceding digits, and constants of this form are conjectured to be either rational or normal to base b.

This paper constructs such formulae for constants of the form $\log p$ for many primes p. This holds for all Gaussian-Mersenne primes and for a larger class of "generalized Guassian-Mersenne primes". Finally, connections to Aurifeuillian factorizations are made.

1 Introduction

The 1997 paper of Bailey, Borwein and Plouffe[2] heralded a new era for the computation of various transcendental constants. For formulae such as the alluring

$$\pi = \sum_{k=0}^{\infty} \frac{1}{16^k}\left(\frac{4}{8k+1} - \frac{2}{8k+4} - \frac{1}{8k+5} - \frac{1}{8k+6}\right)$$

and more generally

$$C = \sum_{k=0}^{\infty} \frac{p(k)}{q(k)b^k}$$

where p and q are integer polynomials, $\deg p < \deg q$, and $p(k)/q(k)$ is non-singular for non-negative k and $b \in \mathbb{Z}^+$, they showed that the n^{th} digit (base b) may be calculated in (essentially) linear time without computing its preceding digits. Moreover, constants of this form are conjectured to be either rational or normal to base b; see Bailey and Crandall[3]. Bailey[1] has recently catalogued a collection of these BBP-formulae.

Curiously, these formulae intersect with the search for prime numbers. Recall that the Gaussian-Mersenne primes (Sloane A057429) are the primes p such that

$$((1+i)^p - 1)((1-i)^p - 1)$$

is prime. Not only will we see that $\log q$ has a BBP-formula for every Gaussian-Mersenne prime q, but also for a much broader sequence of "generalized Gaussian-Mersenne primes."

Section 2 shows how evaluating cyclotomic polynomials at particular complex values yields new BBP-formulae, which in turn is used to motivate the definition of generalized Gaussian-Mersenne primes. In performing such calculations, certain redundancies keep cropping up, shown to be related to Aurifeuillian identities. Section 3 shows how the cyclotomic polynomials can be used to construct such formulae.

2 Cyclotomic Polynomials and Generalized Gaussian-Mersenne Primes

Perhaps the simplest BBP-formula for logarithms is the classical

$$\log 2 = \sum_{k=1}^{\infty} \frac{1}{k2^k}.$$

Bailey *et al.*[2] sought to determine all integers m such that $\log m$ has a *binary* BBP-formula, that is, where $b = 2^l$. Bailey and Crandall noted that the space of constants which admit a binary BBP-formula is linear; if C_1 has such a formula with base 2^{l_1} and C_2 has a formula with base 2^{l_2}, then $C_1 + C_2$ has a formula with base $2^{\mathrm{lcm}(l_1,l_2)}$. Since

$$\log(2^n - 1) - n\log 2 = \log\left(1 - \frac{1}{2^n}\right) = -\sum_{k=1}^{\infty} \frac{1}{k2^{kn}},$$

$\log(2^n - 1)$ has a binary BBP-formula, subsequently yielding formulae for $\log(2^n + 1)$ and the natural logarithm of any integer of the form

$$\frac{(2^{a_1} - 1)\,(2^{a_2} - 1)\cdots(2^{a_h} - 1)}{(2^{b_1} - 1)\,(2^{b_2} - 1)\cdots(2^{b_j} - 1)}. \tag{1}$$

The paper [2] gave a list of some primes which have this form. Bailey [1] extended this list by using the expression

$$\mathrm{Re}\left(\log\left(1 \pm \frac{(1+i)^k}{2^n}\right)\right) \tag{2}$$

suggested by R. Harley and J. Borwein. This expression has a binary BBP-formula since, for example,

$$\begin{aligned}\log\left(1-\frac{1+i}{2^n}\right) &= -\sum_{j=1}^{\infty}\left(\frac{1+i}{2^n}\right)^j\frac{1}{j}\\ &= -\sum_{j=0}^{\infty}\sum_{k=1}^{8}\left(\frac{1+i}{2^n}\right)^{8j+k}\frac{1}{8j+k}\\ &= -\sum_{j=0}^{\infty}\frac{1}{2^{(8n-4)j}}\sum_{k=1}^{8}\left(\frac{1+i}{2^n}\right)^{k}\frac{1}{8j+k}.\end{aligned}$$

A crucial tool for factoring numbers of the form b^n-1 is the classical theory of cyclotomic polynomials:

$$b^n-1=\prod_{d|n}\Phi_d(b) \tag{3}$$

where $\Phi_d(x)$, the d^{th} cyclotomic polynomial, is defined as

$$\Phi_d(x)=\prod_{j=1}^{\phi(d)}(x-\zeta_j).$$

The terms ζ_j are the primitive d^{th} roots of unity and $\phi(\cdot)$ is the Euler totient function. Alternatively, a well-known identity for these polynomials derived using Möbius inversion is

$$\Phi_d(x)=\prod_{k|d}(1-x^{d/k})^{\mu(k)} \tag{4}$$

where $\mu(\cdot)$ is the Möbius function.

In conjunction with expression (1), Bailey *et al.* state that $\log\Phi_m(2)$ admits a binary BBP-formula for all positive integers m. One may easily extend this to

$$\log\ \Phi_m(2^k) \tag{5}$$

for all integers k. However, the cyclotomic polynomials may be used to obtain many other values. Using the Möbius formula (4) with $x=(\pm1+i)/2^n$ yields

$$\mathrm{Re}\left(\log\ \Phi_m\left(\frac{\pm1+i}{2^n}\right)\right)=\sum_{d|m}\mu(d)\mathrm{Re}\left(\log\left(1-\left(\frac{\pm1+i}{2^n}\right)^{m/d}\right)\right). \tag{6}$$

As in the consideration of the expression (2), the right side is a binary BBP-formula. Though it is simply a linear combination of expressions of the form (2), the advantage here is that implicitly some cancellation may take place. For example, we have

$$\mathrm{Re}\left(\log\Phi_6\left(\frac{1+i}{16}\right)\right)=\frac{1}{2}\left[\log 14449-14\log 2\right],$$

hence 14449 joins the list. Similarly, one may use the Möbius formula (4) with $x = (\pm 1 + \sqrt{3}i)/2^n$ to obtain

$$\mathrm{Re}\left(\log\ \Phi_m\left(\frac{\pm 1+\sqrt{3}i}{2^n}\right)\right) = \sum_{d|m}\mu(d)\mathrm{Re}\left(\log\left(1-\left(\frac{\pm 1+\sqrt{3}i}{2^n}\right)^{m/d}\right)\right), \qquad (7)$$

again producing binary BBP-formulae. An example here is

$$\mathrm{Re}\left(\log\ \Phi_5\left(\frac{1+\sqrt{3}i}{4}\right)\right) = \frac{1}{2}\left[\log 331 - 8\log 2\right],$$

so 331 comes onto the list. Again, such results are linear combinations of earlier formulae since, for example,

$$\mathrm{Re}\left(\log\left(1-\frac{1+\sqrt{3}i}{2}x\right)\right) = \log(1-x^3) - \log(1-x).$$

Modest calculations with Maple produced the following augmentation of Bailey's list of primes whose logarithm admits a binary BBP-formula (underlined numbers are given by Bailey[1]):

2, 3, 5, 7, 11, 13, 17, 19, 29, 31, 37, 41, 43, 61, 73, 109, 113, 127,

86798856474727492716312486812789865797648931313763956 9

Of course, products of two primes, three primes, etc. were found to be on the list. Keeping track of these products of primes helps generate new single primes. For example, since $2^{11} - 1 = 23 \times 89$, the product 23×89 is on the list. In addition, we have

$$\mathrm{Re}\left(\log\ \Phi_6\left(\frac{1+\sqrt{3}i}{2^{12}}\right)\right) = \frac{1}{2}\left[\log 7 + 2\log(23\times 89) + \log 599479 - 44\log 2\right],$$

so this is how 599479 was obtained. Products of two primes which are on the list include:

$23 \times 89,\ 47 \times 178481,\ 53 \times 157,\ 59 \times 3033169,\ 67 \times 20857,\ 71 \times 122921,\ 79 \times 121369,$
$83 \times 8831418697,\ 97 \times 673,\ 101 \times 8101,\ 137 \times 953,\ 139 \times 168749965921,\ 149 \times 184481113,\ 181 \times 54001,$
$193 \times 22253377,\ 197 \times 19707683773,\ 229 \times 457,\ 223 \times 616318177,\ 251 \times 4051,\ 277 \times 30269,$
$281 \times 86171,\ 283 \times 165768537521,\ 313 \times 1249,\ 353 \times 2931542417,\ 571 \times 160465489,$
$593 \times 231769777,\ 601 \times 1801,\ 631 \times 23311,\ 641 \times 6700417,\ 1013 \times 1657,\ 1777 \times 25781083,$
$3121 \times 21841,\ 3761 \times 7484047069,\ 5581 \times 384773,\ 8681 \times 49477,\ 10169 \times 43249589,$
$13367 \times 164511353,\ 32377 \times 1212847,\ 92737 \times 649657,\ 179951 \times 3203431780337,$
181549×12112549

Note that all the primes up to 101 are on the list, either alone or multiplied by one other prime. Indeed, every odd prime p is on the list, either alone or in some multiple product of primes since $2^{p-1}-1$ is on the list and $p|(2^{p-1}-1)$. Carl Pomerance (see [2]) showed that 23 could not be written in the form (1); however, it is still unknown whether $\log 23$ has a binary BBP-formula. Related questions are extensively dealt with by Borwein, Borwein and Galway[4].

An important subclass of binary BBP-formulae concerns the expression

$$\mathrm{Re}\left(\log\ \Phi_m\left(\frac{1+i}{2}\right)\right). \tag{8}$$

Letting m equal a prime $p = 4k+1$, we have

$$\begin{aligned}
\Phi_p\left(\frac{1+i}{2}\right) &= 1+\left(\frac{1+i}{2}\right)+\left(\frac{1+i}{2}\right)^2+\cdots+\left(\frac{1+i}{2}\right)^{(4k+1)} \\
&= \frac{\left(\frac{1+i}{2}\right)\left(\frac{1+i}{2}\right)^{4k}-1}{\left(\frac{1+i}{2}-1\right)} \\
&= 1+i\left(1-\left(-\frac{1}{4}\right)^k\right),
\end{aligned}$$

which produces

$$\begin{aligned}
\mathrm{Re}\left(\log\Phi_p\left(\frac{1+i}{2}\right)\right) &= \frac{1}{2}\log\left(1+\left(1-\left(-\frac{1}{4}\right)^k\right)^2\right) \\
&= \frac{1}{2}\log\left(2\cdot 4^{2k}-2(-4)^k+1\right)-2k\log 2 \\
&= \frac{1}{2}\log\left((1+i)^{(4k+1)}-1\right)\left((1-i)^{(4k+1)}-1\right)-2k\log 2 \\
&= \frac{1}{2}\log\left((1+i)^p-1\right)\left((1-i)^p-1\right)-2k\log 2 \\
&= \frac{1}{2}\log\left(\frac{\left((1+i)^p-1\right)\left((1-i)^p-1\right)}{2^{4k}}\right).
\end{aligned}$$

A similar calculation may be done for primes of the form $p = 4k - 1$. We then have that if q is a Gaussian-Mersenne prime, then $\log q$ admits a binary BBP-formula. This connection implies a larger question: For which positive integers m is the numerator of the rational expression

$$\exp\left(2\mathrm{Re}\left(\log\Phi_m\left(\frac{1+i}{2}\right)\right)\right) \tag{9}$$

prime? Besides the Gaussian-Mersenne primes, many composite m satisfy this condition. These generalized Gaussian-Mersenne primes, checked for all $m < 3000$, are listed below (the regular Gaussian-Mersenne primes are underlined).

$\underline{2}, \underline{3}, 4, \underline{5}, \underline{7}, 9, 10, \underline{11}, 12, 14, 15, 18, \underline{19}, 21, 22, 26, 27, \underline{29}, 30, 33, 34, 35, 42, 45,$
$\underline{47}, 49, 51, 54, 55, 58, 63, 65, 66, 69, 70, \underline{73}, \underline{79}, 85, 86, 87, 105, 106, 110, 111, \underline{113}, 114,$
$126, 129, 138, 147, \underline{151}, \underline{157}, \underline{163}, \underline{167}, 178, 186, 189, 217, 231, \underline{239}, \underline{241}, 242,$
$\underline{283}, 319, 323, 350, \underline{353}, 363, \underline{367}, 375, \underline{379}, 385, 391, \underline{457}, 462, 522, 543, 566, 602, 621,$
$633, 651, 679, 741, 779, 819, 871, 885, \underline{997}, 1062, 1114, 1126, 1150, 1226, 1275, 1317,$
$1329, \underline{1367}, 1382, 1434, 1477, 1710, 1926, 1970, 2331, 2422, 2446, 2995.$

Some of the primes produced by expression (9) have been put on the previous list of primes. When $m = 2995$, this produces a prime with over 700 digits.

3 Aurifeuillian Factorizations

Since the cyclotomic polynomials are irreducible in $\mathbb{Z}[x]$, it would seem no further factorization of $b^n - 1$ in equation (3) is possible. However, by imposing certain restrictions on x, other factorizations exist. An example is

$$\Phi_5(x) = x^4 + x^3 + x^2 + x + 1 = (x^2 + 3x + 1)^2 - 5x(x+1)^2$$

which, upon letting $x = 5^{2k-1}$ and factoring the difference of squares, yields

$$\Phi_5(5^{2k-1}) = [5^{4k-2} + 3\cdot 5^{2k-1} + 1 - 5^k(5^{2k-1}+1)][5^{4k-2} + 3\cdot 5^{2k-1} + 1 + 5^k(5^{2k-1}+1)].$$

These special polynomial identities were first noted by A. Aurifeuille and subsequently generalized by E. Lucas. References and other examples of Aurifeuillian identities may be found in Brillhart *et al.* [6], as well as their use in factoring. Theorems regarding writing $\Phi_n(x)$ as a difference of squares may be found in Schinzel[7], Stevenhagen[8] and Brent[5].

Earlier we saw that $\log(2^n \pm 1)$ has a binary BBP-formula. Bailey[1]) notes that

$$\mathrm{Re}\left(\log\left(1 \pm \frac{1+i}{2^n}\right)\right) = \left(\frac{1}{2} - n\right)\log 2 + \frac{1}{2}\log\left(2^{2n-1} \pm 2^n + 1\right),$$

so the two expressions $2^{2n-1} \pm 2^n + 1$ come onto the list. However, multiplying these terms gives the classical Aurifeuillian identity

$$2^{4n-2} + 1 = \left(2^{2n-1} + 2^n + 1\right)\left(2^{2n-1} - 2^n + 1\right).$$

This demonstrates why some calculations used in the last section to generate the list of primes were redundant. Indeed, in searching for various families of factors, similar identities arise. We now develop other Aurifeuillian identities, interesting for their own sake, and make connections to expressions used in the last section. Let us start with a general theorem regarding cyclotomic polynomials.

Theorem 3.1 *Let $m, n \in \mathbf{Z}^+$ satisfy $\gcd(m,n) = 1$ and at least one of m or n is greater than 2. Then*

$$\Phi_{mn}(x) = \prod_{j=1}^{\phi(m)} \Phi_n(x\zeta_j) \tag{10}$$

where ζ_j are the primitive m^{th} roots of unity.

Proof: Since the degree of $\Phi_n(x)$ is $\phi(n)$, the degree of the left side polynomial of (10) is $\phi(mn) = \phi(m)\phi(n)$, matching the degree of the right. The left polynomial is monic, while the leading coefficient of the right side is

$$\begin{aligned} \prod_{j=1}^{\phi(m)} {\zeta_j}^{\phi(n)} &= \left(\prod_{j=1}^{\phi(m)} \zeta_j \right)^{\phi(n)} \\ &= 1 \end{aligned}$$

so the right is also monic. It remains to show that the roots of each side are the same.

The roots of $\Phi_{mn}(x)$ are simply $e^{ki2\pi/mn}$ with $\gcd(k, mn) = 1$. We will show that each of these $\phi(mn)$ distinct roots is also a root of the right side. To expand the right side, first note that each ζ_j has the form $e^{li2\pi/m}$ for some l satisfying $\gcd(l, m) = 1$. This combines to give

$$x\zeta_j = e^{(k+ln)i2\pi/mn}$$

so it is suffices to show that for each k there exists an l such that

$$\gcd\left(\frac{k+ln}{m}, n\right) = 1.$$

Since $\gcd(k, mn) = 1$, we have $\gcd(k, n) = 1$. This implies that $\gcd(k+ln, n) = 1$ and, using the Euclidean algorithm with $\gcd(m, n) = 1$, there exists an l such that $k + ln$ is a multiple of m. This completes the proof. ■

With the identities

$$\Phi_{2^k n}(x) = \Phi_n\left(-x^{2^{k-1}}\right), \quad n \text{ odd}$$

and

$$\Phi_{pn}(x) = \Phi_n(x^p), \quad p \text{ prime}, \ p \not| n,$$

we construct several examples.

Example 3.1 The case $m = 4$ was foreshadowed by Schinzel[7, formula (12)]. Letting n be odd in Theorem 3.1 gives

$$\Phi_n(-x^2) = \Phi_{4n}(x) = \Phi_n(ix)\Phi_n(-ix).$$

Replacing x with ix gives

$$\Phi_n(x^2) = \Phi_n(x)\Phi_n(-x).$$

Example 3.2 Letting $m = 8$, n odd, we have

$$\Phi_{8n}(x) = \left[\Phi_n\left(x\frac{1+i}{\sqrt{2}}\right)\Phi_n\left(x\frac{1-i}{\sqrt{2}}\right)\right]\left[\Phi_n\left(x\frac{-1+i}{\sqrt{2}}\right)\Phi_n\left(x\frac{-1-i}{\sqrt{2}}\right)\right]. \tag{11}$$

Replacing x with $\sqrt{2}x$ yields

$$\begin{aligned}\Phi_n(-4x^4) &= \Phi_{4n}(2x^2)\\ &= \left[\Phi_n(x(1+i))\Phi_n(x(1-i))\right]\left[\Phi_n(x(-1+i))\Phi_n(x(-1-i))\right].\end{aligned} \tag{12}$$

If x is real, the two right side expressions must be integer polynomials since they are each the product of complex conjugates. Example subcases with $x = 2^k$ are
n=1:

$$2^{4k+2} + 1 = (2^{2k+1} + 2^{k+1} + 1)(2^{2k+1} - 2^{k+1} + 1)$$

n=15:

$$2^{32k+16} + 2^{28k+14} - 2^{20k+10} - 2^{16k+8} - 2^{12k+6} + 2^{4k+2} + 1 = L \cdot R$$

where

$$\begin{aligned}L, R \;=\; & 2^{16k+8} \pm 2^{15k+8} + 2^{14k+7} \pm 2^{13k+7} + 2^{12k+7} \pm 2^{11k+7} + 3\cdot 2^{10k+5} \pm 2^{9k+6}\\ & +3\cdot 2^{8k+4} \pm 2^{7k+5} + 3\cdot 2^{6k+3} \pm 2^{5k+4} + 2^{4k+3} \pm 2^{3k+2} + 2^{2k+1} \pm 2^{k+1} + 1\end{aligned}$$

Getting back to the redundancies in our earlier calculations, let $x = 1/2^k$ in (12) to produce

$$\mathrm{Re}\left(\log\ \Phi_{4n}\left(\frac{1}{2^{2k-1}}\right)\right) = 2\left[\mathrm{Re}\left(\log\ \Phi_n\left(\frac{1+i}{2^k}\right)\right) + \mathrm{Re}\left(\log\ \Phi_n\left(\frac{-1+i}{2^k}\right)\right)\right].$$

This shows how terms from (5) and (6) appear in some factorizations.

Example 3.3 Letting $m = 12$ and $2, 3 \not| n$, we have

$$\Phi_{12n}(x) = \Phi_n\left(x\frac{\sqrt{3}+i}{2}\right)\Phi_n\left(x\frac{\sqrt{3}-i}{2}\right)\Phi_n\left(x\frac{-\sqrt{3}+i}{2}\right)\Phi_n\left(x\frac{-\sqrt{3}-i}{2}\right) \tag{13}$$

Replacing x with $2\sqrt{3}x$ gives

$$\Phi_{6n}(12x^2) = \left[\Phi_n\left(x(3+\sqrt{3}i)\right)\Phi_n\left(x(3-\sqrt{3}i)\right)\right]\left[\Phi_n\left(x(-3+\sqrt{3}i)\right)\Phi_n\left(x(-3-\sqrt{3}i)\right)\right]$$

Again, the two right side expressions must be integer polynomials. Example subcases with $x = 2^{k-1}$ are

n=1:

$$9 \cdot 2^{4k} - 3 \cdot 2^{2k} + 1 = (3 \cdot 2^{2k} - 3 \cdot 2^k + 1)(3 \cdot 2^{2k} + 3 \cdot 2^k + 1)$$

n=5:

$$\begin{aligned} & 2^{16k}3^8 + 2^{14k}3^7 - 2^{10k}3^5 - 2^{8k}3^4 - 2^{6k}3^3 + 2^{2k}3 + 1 \\ & \quad (2^{8k}3^4 + 2^{7k}3^4 + 2^{6k+1}3^3 + 2^{5k}3^3 + 2^{4k}3^2 + 2^{3k}3^2 + 2^{2k+1}3 + 2^k 3 + 1) \\ & \quad \times (2^{8k}3^4 - 2^{7k}3^4 + 2^{6k+1}3^3 - 2^{5k}3^3 + 2^{4k}3^2 - 2^{3k}3^2 + 2^{2k+1}3 - 2^k 3 + 1) \end{aligned}$$

To show how equation (13) produces redundancies, replace x with $x(\sqrt{3}+i)/2$ to obtain

$$\Phi_{6n}\left(\frac{1+\sqrt{3}i}{2}x^2\right) = \Phi_{12n}\left(\frac{\sqrt{3}+i}{2}x\right) = \Phi_n\left(\frac{1+\sqrt{3}i}{2}x\right)\Phi_n\left(\frac{-1-\sqrt{3}i}{2}x\right)\Phi_n(x)\Phi_n(-x).$$

With $x = 1/2^{k-1}$ this yields the relationship

$$\begin{aligned} \mathrm{Re}\left(\log \Phi_{6n}\left(\frac{1+\sqrt{3}i}{2^{2k-1}}\right)\right) \;=\; & \mathrm{Re}\left(\log \Phi_n\left(\frac{1+\sqrt{3}i}{2^k}\right)\right) + \mathrm{Re}\left(\log \Phi_n\left(\frac{-1+\sqrt{3}i}{2^k}\right)\right) \\ & + \log \Phi_n\left(\frac{1}{2^{k-1}}\right) + \log \Phi_n\left(\frac{-1}{2^{k-1}}\right). \end{aligned}$$

This shows how terms from (5) and (7) appear in some factorizations.

Acknowledgement: I would like thank David Bailey, Jonathan Borwein and Samuel Wagstaff for supportive dialgoue. Special thanks go to Arnold Adelberg for helping me obtain Theorem 3.1 in its general form.

A CRITERION FOR NON-AUTOMATICITY OF SEQUENCES

Jan-Christoph Schlage-Puchta

Mathematisches Institut
Eckerstr. 1
79111 Freiburg
Germany
jcp@arcade.mathematik.uni-freiburg.de

Abstract

We give a criterion for a sequence $(a_n)_{n\geq 1}$ to be non-automatic, i.e., for when there does not exist a finite automaton generating this sequence. As application we generalize a result of Yazdani on the non-automaticity of multiplicative sequences.

1. Introduction.

A finite automaton consists of a finite set $\mathcal{S}$ of states with a specified starting state s_0, an input alphabet $\mathcal{A}$, an output alphabet $\mathcal{B}$, and two functions $f : \mathcal{A} \times \mathcal{S} \to \mathcal{S}$, $g : \mathcal{S} \to \mathcal{B}$. Given a word w over $\mathcal{A}$, the output of the automaton is determined as follows: At first, the automaton is in s_0. Then the first letter a of w is read, and the new state of the automaton is changed to $s_1 = f(a, s_0)$. Then the next letter b of w is read, and the state of the automaton is changed to $s_2 = f(b, s_1)$. This is repeated untill all letters of w are read, and the procedure terminates. If the automaton ends in the state s, it returns the value $g(s)$.

Fix some integer $q \geq 2$. In our context, the alphabet $\mathcal{A}$ consists of the integers $0, 1, \ldots, q-1$, and $\mathcal{B}$ consists of integers or elements in some fixed finite fields. Every integer $n \geq 1$ can be written in the form $n = \sum e_i(n)q^i$ with $e_i(n) \in \{0, 1, \ldots, q-1\}$, hence n can be viewed as word over $\mathcal{A}$, and the automaton can be applied to this word. More precisely, write $n = \sum_{i=0}^{k} e_i q^i$ with $e_i \in \{0, 1, \ldots, q-1\}$ and $e_k \neq 0$, and identify the integer n with the string $e_k e_{k-1} \ldots e_1 e_0$. In this way, every automaton defines a sequence $(a_n)_{n\geq 0}$. An automaton with $\mathcal{A} = \{0, 1, \ldots, q-1\}$ is called a q-automaton, and an arbitrary sequence is called q-automatic, if there exists a q-automaton which generates this sequence. More generally, a sequence is called automatic, if it is k-automatic for some integer $k \geq 2$.

Apart from intrinsic interest, the question whether a given sequence is automatic is of interest because of its number theoretical consequences. In fact, automaticity and algebraicity are linked via the following result of G. Christol, T. Kamae, M. Mendès France and G. Rauzy [2].

Theorem 1. *Let p be a prime number, $(a_n)_{n\geq 1}$ be a sequence of elements in $\mathbb{F}_p$. Then the series $\sum_{n=1}^{\infty} a_n x^n$ is algebraic over $\mathbb{F}_p(x)$ if and only if the sequence (a_n) is p-automatic.*

Hence, to prove the transcendence of a power series, we need only to show that a certain sequence is not automatic. This can for example be accomplished by the following theorem of A. Cobham [3].

Theorem 2. *Let $(a_n)_{n\geq 1}$ be an automatic seqence over an alphabet $\mathcal{B}$. Assume that for some $a \in \mathcal{B}$ the limit $\delta_a = \lim_{x\to\infty} \frac{1}{x}|\{n \leq x : a_n = a\}|$ exists. Then δ_a is rational.*

In [1], J.-P. Allouche used this to prove the following result.

Corollary 1. *The power series $f(x) = \sum_{n\geq 1}(\mu(n) \bmod p)x^n$ is transcendental over $\mathbb{F}_p(x)$ for all primes p.*

Here, $\mu(n)$ denotes the Möbius-function, i.e., the multiplicative function satisfying $\mu(p) = -1, \mu(p^k) = 0$ for all primes p and integers $k \geq 2$.

Proof. Since $\mu(n) = 0$ if and only if n is divisible by some square $a^2, a \geq 2$, we see that in the notation of Theorem 2,

$$\delta_0 = \lim_{x\to\infty} \frac{1}{x}|\{n \leq x : \exists a \geq 2, a^2|n\} = 1 - \prod_p \left(1 - \frac{1}{p^2}\right) = 1 - \frac{\pi^2}{6},$$

hence, the limit exists and is irrational. So by Theorem 2, the sequence $(\mu(n) \pmod p)_{n\geq 1}$ is not automatic. □

Albeit short and ingenious, the proof has the disadvantage that it is difficult to apply to other situations for two reasons. First, it requires the evaluation of $\prod_p \left(1 - \frac{1}{p^2}\right)$ and a proof that the result is irrational. This is equivalent to Euler's evaluation of $\zeta(2)$ and the fact that π^2 is irrational. In our case, these are well known, yet non-trivial facts. However, in other cases there might be no known formula for δ_a. The second, more fundamental problem is that in many cases $\delta_a = \frac{1}{|\mathcal{B}|}$ for all a, so Theorem 2 cannot be applied.

The aim of this note is to give another proof of Corollary 1. In fact, we have the following more general result.

Theorem 3. *Let $(a_n)_{n\geq 1}$ be an automatic sequence. Assume that for some letter a and for every integer k there exists an integer n such that $a_n = a_{n+1} = \cdots = a_{n+k} = a$. Then there is a constant $c > 0$ such that for an infinite number of integers x we have $a_n = a$ for all $n \in [x, (1 + c)x]$.*

Other criteria involving strings of repeated values can be found in [4].

2. Main results

Before proving our theorem, we first give some corollaries.

Corollary 2. *Let $(q_i)_{i\geq 1}$ be a sequence of positive integers such that $\sum_i \frac{1}{q_i} < \infty$. Assume that for all $k \geq 1$, there are indices $i_1, \ldots, i_k$ such that $(q_{i_l}, q_{i_m}) = 1$ for $1 \leq l < m \leq k$. For all integers $n \geq 1$, set $a_n = 0$, if there exists some i such that $q_i|n$, and $a_n = 1$ otherwise. Then the sequence $(a_n)_{n\geq 1}$ is not automatic.*

Proof. Assume that the sequence $(a_n)_{n\geq 1}$ is automatic, and let k be a given integer. Choose indices $i_1, \ldots, i_k$ as in the Corollary. By the Chinese remainder theorem, there is some integer n solving $n + l \equiv 0 \pmod{q_{i_l}}$, that is, $a_{n+l} = 0$ for $1 \leq l \leq k$. Hence, the assumptions of Theorem 3 are satisfied, and we deduce that there exist some $c > 0$ and arbitrarily large integers x such that $a_n = 0$ for all $n \in [x, (1+c)x]$. On the other hand, we can bound from below the number of integers $n \in [x, (1+c)x]$ such that $a_n = 0$ in the following way. Let $\epsilon > 0$ be given, and let K be some constant with $\sum_{i>K} \frac{1}{q_i} < \epsilon$. Let L be the least common multiple of $q_1, \ldots, q_K$. Then the set of all integers n such that $q_i \not| n$ for all $i \leq K$ is periodic with period L, and has density $d_K \geq \prod_{i\leq K} \left(1 - \frac{1}{q_i}\right)$, with equality if and only if the q_i are pairwise coprime. Note that

$$d_K > \prod_{i=1}^{\infty} \left(1 - \frac{1}{q_i}\right) > 0,$$

that is, d_K can be bounded away from 0 independently of K. Now for $x \to \infty$, we have

$$\begin{aligned} |\{n \in [x, (1+c)x] : a_n = 1\}| &\geq |\{n \in [x, (1+c)x] : \forall i \leq K : q_i \not| n\}| \\ &\quad - \sum_{i>K} |\{n \in [x, (1+c)x] : q_i | n\}| \\ &\geq d_K cx - L - \epsilon cx - |\{i : q_i \leq (1+c)x\}| \\ &\geq (d_K - \epsilon)cx + o(x), \end{aligned} \tag{1}$$

since $|\{i : q_i \leq (1+c)x\}| = o(x)$, for otherwise the series $\sum \frac{1}{q_i}$ would diverge. In fact, if

$$\limsup_{x\to\infty} \frac{|\{i : q_i < x\}|}{x} > 0,$$

there exists some constant $k > 0$ such that

$$\limsup_{n\to\infty} \frac{|\{i : 2^n \leq q_i < 2^{n+1}\}|}{2^{n+1}} > k,$$

thus, $\sum_i \frac{1}{q_i} = \infty$. By Theorem 3 we would find arbitrarily large integers x such that the left-hand side of (1) is zero, thus we arrive at a contradiction. So the sequence $(a_n)_{n\geq 1}$ is not automatic. □

Choosing $q_i = p_i^2$, with p_i the i-th prime number, we find that the sequence $(\mu(n)^2 \pmod p)_{n\geq 1}$ is not automatic, which is slightly stronger then Corollary 1.

Out next result deals with the automaticity of multiplicative functions.

Corollary 3. *Let $f : \mathbb{N} \to \mathbb{Z}$ be a multiplicative function. Let $q \geq 2$ be an integer. Assume that the following conditions hold.*

1. *There exist infinitely many primes p such that there exists some $h_p \geq 1$ with $q | f(p^{h_p})$.*
2. *If b_n denotes the n-th integer with $f(b_n) \not\equiv 0 \pmod q$, we have $\frac{b_{n+1}}{b_n} \to 1$.*

Then the sequence $(f(n) \pmod q)_{n\geq 1}$ is not automatic.

Proof. As in the proof of Corollary 2, the first condition implies that for every k there exist some n with $f(n) \equiv f(n+1) \equiv \cdots \equiv f(n+k) \equiv 0 \pmod q$, while the second condition means that for every $c > 0$ there are only finitely many integers x such that $f(n) \equiv 0$

(mod q) holds for all $n \in [x, (1+c)x]$. Together with Theorem 3, we obtain the desired conclusion. □

This result generalizes a theorem of S. Yazdani [5, Theorem 2]. In fact, the conditions on f are relaxed in two aspects: First, the integers h_p are allowed to depend on p. More important, the lower bound for the density of the set of integers n satisfying $q \nmid f(n)$ in the second condition of Corollary 3 is smaller then in [5, Theorem 2]. The latter theorem requires $q \nmid f(p)$ for all primes in a residue class, which by the prime number theorem for arithmetic progressions implies condition (2) of Corollary 3.

Now we return to the proof of Theorem 3.

Proof of Theorem 3. Assume that $(a_n)_{n\geq 1}$ is a sequence satisfying the conditions of Theorem 3, and it is generated by a q-automaton. For every integer l, let n be an integer such that $a_{n+i} = a$ for all $i \leq q^l$. We may assume that n is divisible by q^l. Indeed, by hypothesis, for all integers $l \geq 1$ there exists an integer m such that $a_{m+i} = a$ for $0 \leq i < 2q^l$. Let n_l be the least integer such that $n \geq m$ and $q^l | n$. Then $n < m + q^l$, and therefore $a_{n+i} = a$ for $0 \leq i < q^l$. Let s be the state of the automaton reached when reading all digits of n except the last l digits. Then the definition of s implies that all states accessible from s within precisely l steps return a. To every state s define a set $\mathcal{N}_s \subseteq \mathbb{N}$ such that $l \in \mathcal{N}_s$ if and only if all states accessible from s within precisely l steps return a. Our argument above shows that for every $l \in \mathbb{N}$ there is some state s accessible from the starting state such that $l \in \mathcal{N}_s$. Hence, since there are only finitely many states, there exists some s_0 such that s_0 is accessible from the starting state, and there are infinitely many l such that all states accessible from s_0 in precisely l steps return a. Let d be some integer such that when reading d, the automaton stops in the state s_0. Then we claim that for all $l \in \mathcal{N}_{s_0}$ and all $n \in [dq^l, dq^l + q^l - 1]$, we have $a_n = a$. In fact, after reading d, the automaton is in state s_0, then, after reading l arbitrary digits, it is in some state returning a. Hence, our theorem follows with $c = (1 - q^{-1})d^{-1}$. □

On Happy Factorizations

J. H. Conway
Department of Mathematics
Princeton University, Princeton NJ 08544
Email address: conway@math.Princeton.EDU

Abstract: (Supplied by the editors.) It is asserted without proof that every positive integer is the product of a unique "happy couple" of integers. A "happy couple" is an ordered pair of integers of one of three types: (*A*,*A*) ; (*B*,*C*), with $C > 1$, where there exist integers *R*, *S* such that $B R^2 + 1 = C S^2$; and (*D*, *E*) where there exist odd integers *T*, *U* such that $D T^2 + 2 = E U^2$.

Any ordered couple of integers that can be obtained from the positive integers (*n*,*n*+*d*) by dividing them by possibly distinct perfect squares prime to *d* is called a "*d*-happy couple", except that couples of the form (*m*,1) are NOT called 1-happy.

A "happy couple" is just a *d*-happy couple for $d = 0$, 1 or 2.

Theorem. *Each positive integer N is the product of a unique happy couple.*

I call this "the happy factorization" of *N*, and append a table of happy factorizations, writing a number as

A^2 *B*.*C* or *D*:*E*

according as it is the product of a

0-happy couple (*A*,*A*), 1-happy couple (*B*,*C*), or 2-happy couple (*D*,*E*).

Introduction

The well-known number theory text of Hardy and Wright contains the following remark ([HW], p.373):

> "Bertrand's Postulate" is that, for every $n > 3$, there is a prime p satisfying $n < p < 2n-2$. Bertrand verified this for $n < 3,000,000$ and Tchebychef proved it for all $n > 3$ in 1850.

Bertrand's Postulate is essentially equivalent to the statement that the first $2k$ integers can always be arranged in k pairs so that the sum of the entries in each pair is a prime. We give the simple proof of this statement, and discuss some generalizations whose proofs seem to be quite intractable, even though they can be supported by numerical exploration and simple probabilistic analysis.

Easy results

Theorem 1. The integers $\{1, 2, ..., 2k\}$ can be arranged into k disjoint pairs so that the sums of the elements in each pair is prime.

Proof. We prove this by complete induction. The assertion is true when $k=1$ since 3 is prime. Now consider the set of integers $\{1, 2, ..., 2k\}$, and assume that all the sets $\{1, 2, ..., 2j\}$ have been successfully paired where j is any integer in the range $0 < j < k$. We begin by trying to pair $2k$ with some other number. The possible pairs are $(j, 2k)$ with $0 < j < 2k$. The sums of these pairs are all the integers from $2k+1$ to $4k-1$. Since $2(2k+1) - 2 > 4k-1$ Bertrand's Postulate insures that one of these numbers, say $2k+m$, is a prime. But m is odd, so the set $\{m, m+1, ..., 2k-1, 2k\}$ has an even number of elements. This set can be paired so that the sum of the elements in each pair is the prime $2k+m$: just pair $m+1$ with $2k-1$, $m+2$ with $2k-2$, etc. The proof is done because our inductive assumption implies that the initial segment from 1 to $m-1$ can be paired so that the sum of the elements in each pair is a prime. ¤

Definition 1. A sequence of integers $\{a_k\}$ has the *combinatorial Bertrand property* (the *CB property*) if, for all k, the numbers $\{a_1, a_2, ..., a_{2k}\}$ can be written as k disjoint pairs so that the sum of the elements in each pair is prime. A integer-valued function f will have the *CB property* if the sequence $\{f(k)\}$ has the CB property.

Note. The fact that $f(k)=k$ has the CB property is essentially *equivalent* to Bertrand's Postulate. For if we know that for every positive integer k, there is m with $0 < m < 2k$ so that $2k+m$ is prime, then (taking $n = 2k$) there must be a prime between n and $2n$. A simple adjustment can be made for odd n so a form of Bertrand's Postulate must be true.

What other functions have the CB property? Simple numerical experiments lead to the belief that many functions do or that they have the CB property "eventually". For example, suppose f is a polynomial of degree 1 ($f(n)=an+b$), and property CB holds. Then $f(n)+f(m)= a(n+m) + 2b$ must be prime infinitely often. By the classical result of Dirichlet on primes in arithmetic progressions this is equivalent to asking that $\gcd(a,2b) = 1$. This Dirichlet condition does *not* imply the CB property, however: consider the function $f(n)=11n+1$ and the set of the first $2k$ values of f when $k=1$. But such functions most likely eventually satisfy CB.

Definition 2. A sequence of integers $\{a_k\}$ has *the CB property eventually* if there is K so that for all $k > K$, the numbers $\{a_1, a_2, ..., a_{2k}\}$ can be written as k disjoint pairs so that the sum of the elements in each pair is prime. An integer-valued function f is *eventually CB* if the sequence $\{f(k)\}$ is eventually CB.

We suspect the following result is true:

Conjecture 0. If $f(n)= an+b$ and a and b satisfy the Dirichlet condition $\gcd(a,2b)=1$, then f is eventually CB.

The proof would imitate that of Theorem 1 above. If $M(K)$ is the number of primes less than K of the form $ak+b$, then $M(K)$ is approximately $C\,K/(\log K)$ where C is a constant (the reciprocal of the Euler phi function at a). For example, see [E], p. 17, where an error estimate ($O(K \exp(-c (\log K)^{1/2})$ with $c > 0$) is also given. We'd like to apply the proof of Theorem 1 here. Certainly for K large it is easy to see

that $M(2K) > M(K)$. Then the numbers $\{a+1, a+b, a+2b, ..., a+Kb\}$ can be matched up as in the proof of Theorem 1. But the complete induction of Theorem 1 does not immediately apply. Given the evidence at hand, it may possibly be true that we can successfully match some top part of an initial segment of values of f without having enough successful matching to take care of what's left. That is, consider the set $\{f(1), f(2), ..., f(2K)\}$. Certainly for K large we can find j odd with $f(j)+f(2K)$ prime. Then the set $\{f(j), f(j+1), ..., f(2K)\}$ can be divided into pairs whose sums are prime and all the same: $f(j)+f(2K)$. But j could be small, and the set $\{f(1), f(2), ...,f(j-1)\}$ could perhaps not be successfully matched into pairs whose sums are prime. We thank Professor Andrew Granville for pointing out this difficulty. Either better asymptotics are needed or a better proof! In specific cases, such as $f(n)=3n+1$ it seems apparent that some initial computation plus constants known well enough can establish the eventual CB property.

Probabilistic analysis and experimental evidence

The structure of an arithmetic progression and Dirichlet's Theorem make the consideration of linear functions easy. We have experimentally investigated whether several other functions appear to have the CB property. For example, the function $f(k)=k^2$ seems to have property CB. We have found pairings of the first $2k$ squares for k up to 1 000 using a computer. This is encouraging, since the discussion of Conjecture 0 suggests that difficulty is most likely to occur with small k. A slightly more explicit probabilistic analysis gives the following result:

"Theorem 2". The probability that the set $\{1^2, 2^2, ..., (2k)^2\}$ can be broken up into k pairs so that the sum of the elements of each pair is a prime approaches 1 as k approaches infinity.

"Proof". The Prime Number Theorem states that there are about $K/(\log K)$ primes less than or equal to K. Thus the chance that t randomly selected integers in the range $[1,K]$ are prime is approximately $(\log K)^{-t}$. If we fix a positive integer k, and try to find a pairing of the set$\{1^2, 2^2, ..., (2k)^2\}$, then $K= 4k\text{^}2$ and $t=k$. The expectation of success will be enhanced since we can try all possible pairings of the set, and there are $(2k)!/ (2^k k!)$ such pairings. Thus we will expect success if the limit as k tends to infinity of $(\log (4k\text{^}2))^{-k}((2k)!/ (2^k k!))$ is at least 1. This can be verified by replacing the factorials using Stirling's formula. The condition above then reduces to showing that $2^{½}(2k/e)^k(\log(8k^2)^{-k}$ is at least 1. This is true since log growth is slower than polynomial growth. ¤

Comments. The use of the quotes (" and ") in both the Theorem and the Proof above is certainly justified, since both the statement and the verification are more approximate than precise. What is really shown is that any sequence with at most, say, polynomial growth (such as k^2), will have "the CB property" relative to a "sparse" sequence such as the primes. We have implicitly made assumptions about uniform distribution and independence which are not valid here. First, the sums of the elements in each pair are far from random relative to the primes (e.g., the function $f(k)=2k^2$ would give a sequence with the same asymptotic properties, but of course every sum $f(k)+f(j)$ would be composite). Secondly, both the primes and the squares are not uniformly distributed. There are more "small" primes than there should be, and the squares are more concentrated in the lower portion of their range. This coincidence

may in fact aid in obtaining successful pairings. Third, unlike what is understood in the "Proof", there is substantial dependence among the possible sets of pairings and their primality. For example, 3^2+4^2 is not prime, and thus any collection of pairings which included (3,4) in its list could not be successful. All these remarks apply to any polynomial function. In the case of $f(k)=k^2$ there is an additional obstacle, due to Fermat and Euler, to the analysis above, which implicitly assumes independence: only primes of the form $4m+1$ can be written as the sum of two squares, and each such prime can be so written in exactly one way (up to order). Thus if (4,1) is used as one pair, no other pair summing to a prime of the form $4m+1$ which can be written as k^2+1 (e.g., 37) can be used in the "dissection" of $\{1^2, 2^2, ...,(2k)^2\}$. So there is more complex dependence than the "Proof" allows.

In spite of the above objections, experimental evidence shows that there are far *more* successful pairings than predicted by the rough probabilistic "Proof" above. Below is a table of what happens for k between 1 and 10 in both the linear ($f(k)=k$) and quadratic ($f(k)=k^2$) cases. We give the "expected" number of successful complete pairings predicted using a Stirling's formula approximation (for the quadratic case as in the "Proof" above, and for the linear case with $K=4k$). We show the number actually observed. For background, we also present the total number of possible complete pairings (our probabilistic universe) in each case.

k =	1	2	3	4	5	6	7	8	9	10
# of complete pairings	1	3	15	105	945	10 395	135 135	2 027 025	34 459 425	654 729 075
Expected number of successes (linear case)	.7505	.7081	.9912	1.795	3.949	10.15	29.80	97.89	355.2	1 409
Actual # of successes (linear case)	1	2	3	6	26	96	210	1 106	3 759	12 577
Expected # of successes (quad. case)	.5004	.2549	.1944	.1914	.2282	.3174	.5022	.8883	1.733	3.691

Actual # of successes (quad. case)	1	1	2	4	12	9	72	160	428	2 434

We cannot explain the interesting large discrepancies in the figures above.

It is possible to obtain functions which are far from having the CB property but which also have pairwise relatively prime values.

Theorem 3. There exist injective integer-valued functions f with gcd($f(i)$, $f(j)$) = 1 for all positive integer i and j, and such that $f(i)+f(j)$ is composite for all positive integer i and j.

Proof. We give a simple "lacunary" construction of one such function. First, for each integer K we construct an integer-valued function g_K which signals K-long segments of composite integers. Namely, take $g_K(t)= (K+1)!\ t + 1$. Then for every K and t, gcd(s,$g_K(t)$) =1 for s between 1 and K. Also, $g_K(t)+s$ is composite for such s. In order to obtain a function satisfying the theorem, merely assume that $f(1), f(2), ..., f(m)$ have already been defined. We can also assume that $f(1) < f(2) < ... < f(m)$. Take $K=f(m)$, and define $f(m+1) = g_K(1)$.

Note. The (non-unique) function created in the theorem is increasing. For example, if we begin by assuming $f(1)=1$ then $f(2)=3$, $f(3)=7$, $f(4)=5\ 041$ and $f(5)$ is approximately $10^{16\,480}$. So f is very rapidly increasing. Are there simple functions with slower growth which satisfy the conclusions of this theorem? The probabilistic assertions of "Theorem" 2 do *not* apply to the functions constructed here because of their rapid growth.

Conjectures

We've tested a number of examples of functions to see if they display CB behavior. $f(k)=k^3$ does not have the CB property since $k^3+j^3 = (k-j)\ (k^2 +kj +j^2)$. But $f(k)= k^4$ does seem to have the CB property, based on experiment. Our experiments have led us to the following statement.

Conjecture 1. Suppose f is a polynomial with integer coefficients which is positive for positive k. Then f has property CB eventually if and only if $f(k)+f(j)$ is an irreducible polynomial in two variables and $f(k) +f(j)$ has content 1.

"Content" here means the gcd of the coefficients of a polynomial, and is the natural generalization of the Dirichlet condition of Conjecture 0. Certainly the conditions of this Conjecture are necessary, and the probabilistic analysis of "Theorem" 2 makes it natural to hope that they are sufficient. Of course the CB problem can be restated as a graph-coloring problem, where the nodes are the integers {1, 2, ..., $2k$}, and

two nodes *k* and *j* are connected by an edge exactly when *f(k)+f(j)* is prime. This seems to offer no enlightenment, but does lead to a somewhat generalized conjecture. We could put in edges where other functions are prime (e.g., $k^2 + kj + j^2$), or we can even investigate more general examples (analogous to directed graphs). Namely, we can study any polynomial in two variables, rather than one which is symmetric in its two variables. Then the CB property itself will lose some symmetry, but here is one possible generalization:

Conjecture 2. Suppose *p(k,j)* is a polynomial in two variables with integer coefficients, and *p* is irreducible with content 1. If *n* is sufficiently large, then the set {1, 2, ..., *2n*} can be arranged into *n* disjoint pairs so that if (*a*,*b*) is one pair, either *p(a,b)* or *p(b,a)* is prime.

Numerical experiments with several polynomials (e.g., $k+j^2$, k^2+j^3, and k^2+kj+j^2) have been done. The experiments seem to support the conjecture.

We can further generalize by looking at "higher order" versions of the CB property:

Definition 3. Suppose *N* is a positive integer. A sequence of integers $\{a_k\}$ has the N^{th} order combinatorial Bertrand property (the N^{th} order CB property)} if, for all *k*, the numbers $\{a_1, a_2, ..., a_{Nk}\}$ can be written as *k* disjoint sets of *N* elements so that the sum of the elements in each set is prime.

One can make obvious generalizations to fit the phrases: a function has the N^{th} order CB property or a sequence (or function) has the N^{th} order CB property eventually. When $N = 1$, such sequences have to be subsequences of the primes. A simple conjecture which we are unable to verify is the following:

Conjecture 3. The sequence of odd integers {1, 3, 5, ... } has the third order CB property eventually.

Again, probabilistic reasoning coupled with the obvious necessary conditions applied here to the polynomial $2 (k + j + i) + 3$ seem to suggest the truth of Conjecture 3.

A additional natural collection of sequences to study for CB behavior would be sequences defined by simple linear recursions. For example, consider the sequence defined by the following recursion and initial condition: $a_{n+1} = 2\, a_n + 1$ with $a_1 = 1$.

This recursion can be solved explicitly to obtain $a_n = 2^n - 1$. Does this sequence have the third order CB property? Here the probabilistic reasoning does not apply because of the growth of $\{a_n\}$. But the sequence is on the borderline probabilistically. Deciding if such exponentially growing sequences are eligible seems to need more information than we have.

On the other hand, functions with finite range are also of interest. In trying to determine how many distinct functions with finite range there are which have the N^{th} order CB property, we come across the

following extremal problem:

Problem 1. Suppose S and T are positive integers. Find a set of integers $\{a_1, ..., a_S\}$ with the maximum number of T element subsets which sum to a prime. What is this number and this set?

Is an initial segment of the integers such an extremal set?

These questions all seem to be difficult because even the simplest non-linear case (does $f(k)=k^2$ have the CB property?) approaches the limits of current knowledge. For example, it is not known if there are infinitely many prime numbers of the form k^2+1 (see the discussion in the Appendix to [HW]). While this question may be independent of the CB property for this f, its difficulty does not suggest that the proof of the CB property for this f will be immediate.

Finally, we have a question about algorithms. Suppose we're given an integer-valued function, f. How can we check if some initial values of f have the CB property? Since the number of pairs to be checked is very large, any way to shrink this number is worth considering. It is disconcerting to report that a sort of **Greedy Algorithm** seems to work even when there is no justification. The Greedy Algorithm is motivated by the proof of Theorem 1. Suppose f is increasing (e.g., $f(k)=k$ or $f(k)=k^2$). In order to check pairs in the set $\{ f(1), f(2), ..., f(2n)\}$, first find a match for the largest element (if possible). That is, find j between 1 and $2n$ so that $f(j)+f(2n)$ is prime. Remove $f(j)$ and $f(2n)$ from the list and continue, again trying to match the largest element. Continue matching elements and removing pairs in this fashion as long as possible. We'll say that the Greedy Algorithm is successful if this procedure results in the empty set. Of course the Greedy Algorithm reduces verifying property CB to an $O(n^2)$ number of prime checks (a large reduction from the indicated number!). The Greedy Algorithm need not be successful (a simple example is the list {1,8,9,10}, where the algorithm grabs 9 and 10 and is left with 1+8=9, and doesn't find {1,10} and {8,9}).

The proof of Theorem 1 shows that the Greedy Algorithm must be successful for $f(k)=k$. However, the Greedy Algorithm has been successful in every example we have checked for $f(k)=k^2$. It does not seem to work with some other polynomials. If $f(k,j) = k^2 + k\,j + j^2$, the number of pairs to be checked seems to grow very quickly with n (e.g., when $n = 20$, we needed to check 213 347 331 pairs).

Problem 2. Is the Greedy Algorithm always successful for $f(k)= k^2$?

It is possible that we've just been lucky because there are many coincidences for small numbers.

The Computation of Certain Numbers Using a Ruler and Compass

Simon Plouffe
Dépt. Mathématiques
Université du Québec à Montréal
Montréal H2X 3Y7, CANADA
Email address: simon.plouffe@sympatico.ca

Abstract: We present a method for computing some numbers bit by bit using only a ruler and compass, and illustrate it by applying it to arctan(X)/Pi. The method is a **spigot algorithm** and can be applied to numbers that are constructible over the unit circle and the ellipse. The method is precise enough to produce about 20 bits of a number, that is, 6 decimal digits in a matter of minutes. This is surprising, since we do no actual calculations.

Keywords : Binary expansion, A004715 of the On-Line Encyclopedia of Integer Sequences, constant, ruler and compass construction, Pi.

1. Introduction

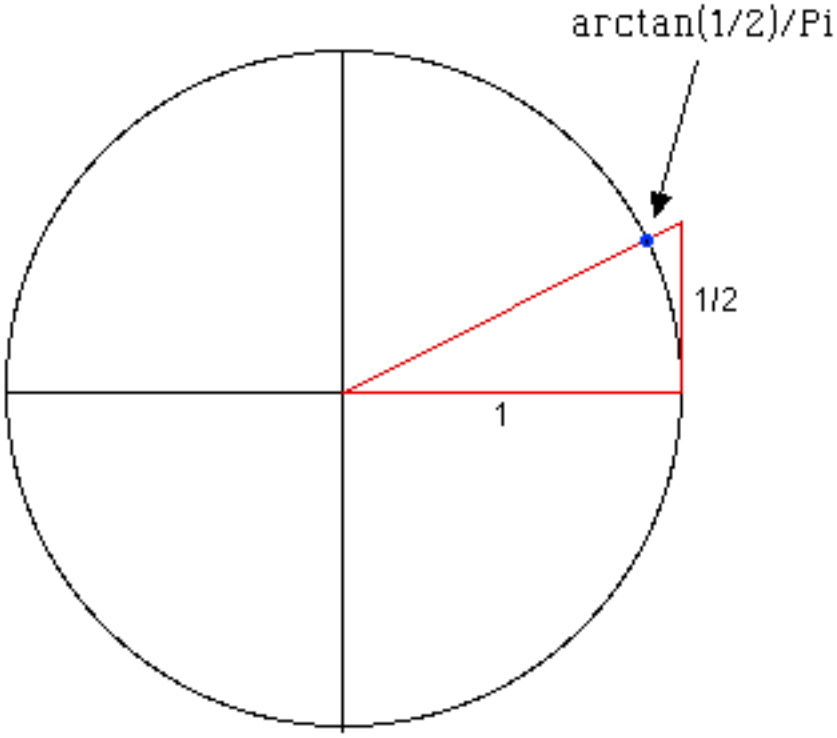
It is known that rational numbers of the form 1/q can be computed with a ruler and compass in small bases. See **[4]** for details. The rational numbers computable by this method are precisely those for which q is the number of sides of a regular polygon that can be constructed with ruler and compass; that is, q must be a product of distinct Fermat numbers that are primes **[5]**, see also the Treasure Trove of Mathematics.

From those facts, one can ask : are there other points on the unit circle that can be constructed ? The answer is obvious: any line constructed on the plane that crosses the unit circle somewhere defines a point from which the binary expansion can be calculated. We understand here that we consider the arc length compared to the unit circle. When we consider a rational number like 2/3 we mean in fact exp (2*Pi*I*2/3), that is, the arc length of 2/3 compared to 2*Pi on the unit circle. By taking a simple construction of the angle arctan(1/2) then get an arc length of arctan(1/2)/Pi = 0.147583.... A number

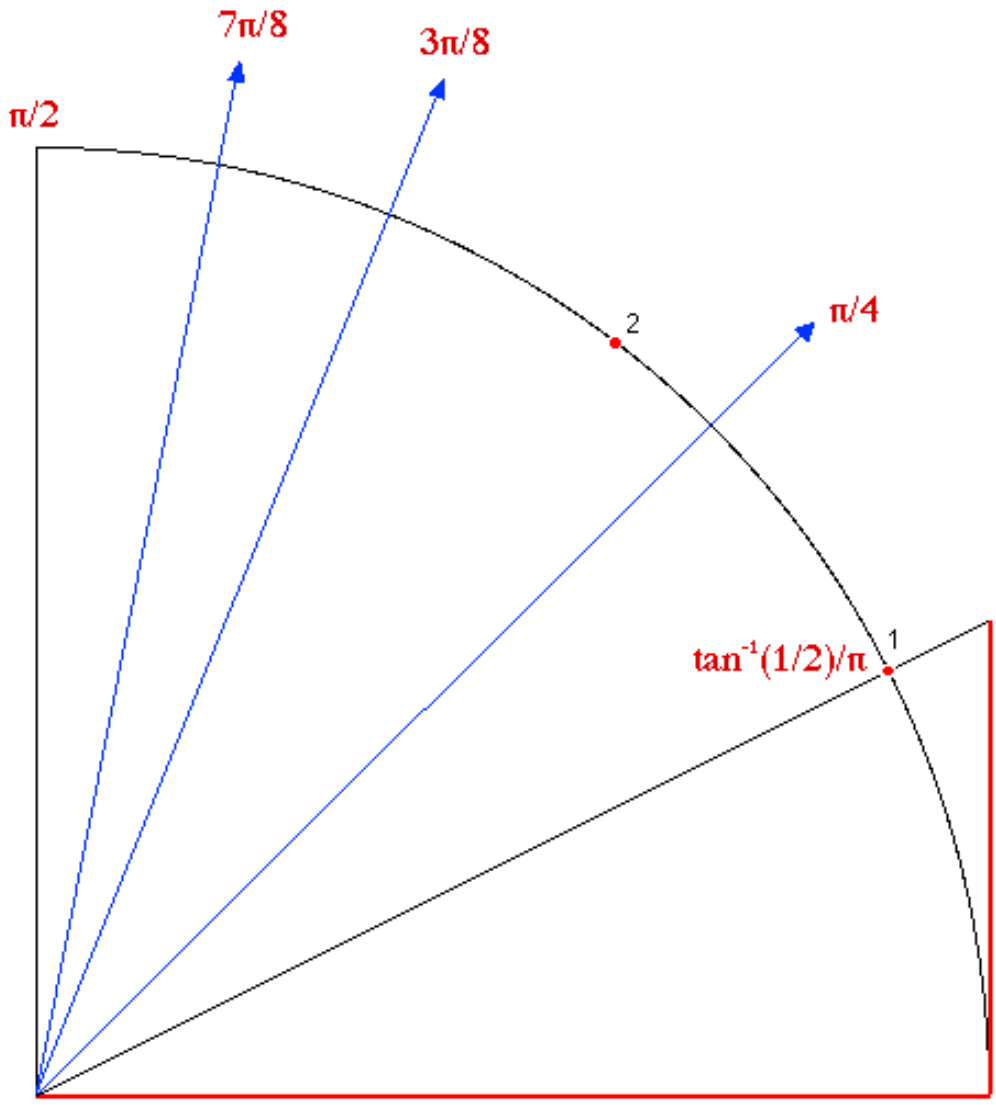
that we believe should be at least irrational. We also remark that the point defined by the angle of arctan (1/2) has algebraic coordinates (2/5*sqrt(5) and 1/5*sqrt(5)), and that this point (on the unit circle) is **apparently not** a rational multiple of Pi. We do not know if there is a proof that this number is irrational.

Second, the arctan function is a log (with complex values) and Pi is also a log with complex values. This means that our construction is a ratio of logarithmic values.

2. The construction of arctan(1/2)/Pi and the computation



The coordinates of the blue dot are (2/5*sqrt(5), 1/5*sqrt(5)).
Each subdivision of the circle is equivalent to a rational point, here Pi/2 is 0.01 in binary = 1/4.



Only the first quadrant is necessary for the computation, see the construction after 11 steps.

At each step we double the angle and when the point falls in the first quadrant we take the sign of the angle. If the sign is + then we set that the corresponding bit value is 0 and 1 when the sign of the angle is -. By doing it by hand for real, errors accumulate and eventually there is an ambiguity in the sign since at each step there is an uncertainty about the exact position of the point. The limit is somewhere around 20 bits. I could easily produce (with little care) the first 17 bits of the number arctan(1/2)/Pi. Note : the construction is done on a plain white paper and could be done on the sand in fact with small precision.

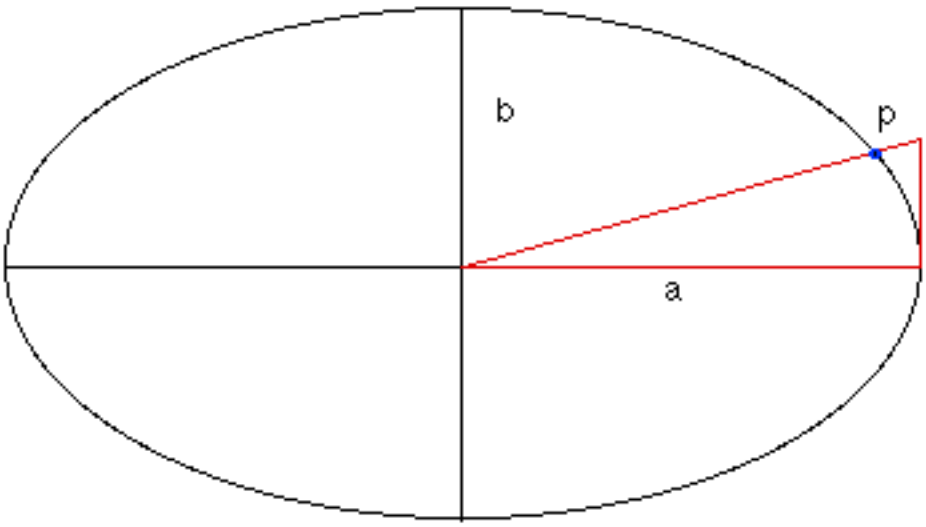
3. Other numbers.

Since we can compute any point that lies on the unit circle then any construction that cuts that circle is computable. This includes numbers of the form arctan(A)/Pi where A is algebraic and constructible with a ruler and compass. According to Borwein and Girgensohn **[2]**, it is possible to compute bit by bit a number like log(3)/log(2, but the geometrical construction necessary for that implies the use of a

rectangular grid **Z x Z.**

4. Application to the ellipse

The properties of the circle are not unique, it is also shared with the ellipse and the lemniscate. In this context it means that if we can construct an angle that crosses the ellipse of ratio a/b then we can compute the binary expansion of the position of that point compared to the **arc length of the ellipse**. The same can be applied to the lemniscate.



The point p compared to the arc length from (a,0) to p is computable in binary.

5. An experimental approach to search for other solutions

The next step in this is to ask whether we can combine values of arctan(X)/Pi to produce other numbers like sqrt(2). From the classical theory of Pi (Lindemann's proof of the transcendence of Pi), it is not possible to get 1/Pi from a geometrical construction. In this context it means that we can't construct an arc length of 1 radian with the ruler and compass. 1 radian has an arc length of 1/Pi. It would mean that we can construct the number sin(1) and cos(1). The only way I see to produce an example is to try experiments with values of arctan(X)/Pi where X is a constructible algebraic number.

We have to understand here that we deal with an inverse problem. The equation arctan(1/2)+arctan(1/3) =Pi/4 translates (in arc length), to 1/8 in binary. Pi/4 = arctan(1) and this number have an arc length of 1/8 compared to the full circle of 2*Pi.

Open questions

Can this process could be applied to other types of numbers? (Like sqrt(2)).
Since we can use the first quadrant only (and not a full circle), can we extend this idea to have only a very small portion of the unit circle and push the precision of the computation further?
Are there any simpler number? Or in other words : Is arctan(1/2)/Pi the simplest example?

Is arctan(1/2)/Pi an irrational number? (Hint : Pi/4 = arctan(1/2)+arctan(1/3) and we know that Pi is irrational).
Is there a bit pattern in arctan(1/2)/Pi? Is the binary expansion of that number in fact a rule for constructing something that we do not know? See sequence A004715 of the E.I.S.

A Connell-Like Sequence

Gary E. Stevens
Department of Mathematics
Hartwick College, Oneonta, NY 13820
Email address: StevensG@Hartwick.edu

ABSTRACT

We introduce a generalization of the Connell Sequence, generated by using groups of q terms each a multiple of q (rather than just being even or odd as q is), and find an expression for the general term.

INTRODUCTION.

The Connell Sequence 1, 2, 4, 5, 7, 9, 10, 12, 14, 16, ... (A001614 in the *On-Line Encyclopedia of Integer Sequences*) is generated as follows:

take the first odd integer, the next two even integers, the next three odd integers, the next four even integers, etc.

In 1959 Ian Connell [1] posed the problem of proving that this sequence has general term:

$$u_n = 2n - \text{Floor}(\tfrac{1}{2}(1 + \text{Sqrt}(8n - 7)))$$

where Floor(x) is the largest integer less than or equal to x. A solution appeared in [2]. The sequence has some practical applications in antenna theory [3] and some of its properties have also been studied in [4].

In this article we consider the following generalization of the Connell Sequence.

Definition: Let $\{S_n\}$ be the Connell-like sequence generated as follows:
Take the first multiple of one, the next two multiples of two, the next three multiples of three, the next four multiples of four, ..., the next q multiples of q, etc.

The resulting sequence (now A033291) is

1, 2, 4, 6, 9, 12, 16, 20, 24, 28, 30, 35, 40, 45, 50, 54, 60, ...

THE DISCOVERY.

Let q denote the multipliers used in the sections of the general sequence so that q runs through all positive integer values

and is used as a multiplier q times. Note that the subscript of the last term of the section which uses the multiplier q will be the q^{th} triangular number, t_q. Thus, if n is any subscript appearing in the section of the sequence using the multiplier q, then

$$t_{q-1} < n <= t_q = \tfrac{1}{2}\,(q(q + 1)).$$

Solving for q in terms of n, we find q must be the smallest (non-negative) integer satisfying the quadratic equation $q^2 + q - 2n = 0$. Using Ceiling(x) to indicate the least integer greater than or equal to x, we can write

$$q_n = q(n) = \text{Ceiling}\,(\tfrac{1}{2}\,(-1 + \text{sqrt}(1 + 8n)))$$

to express the multiplier used for the n^{th} term of the sequence. To begin developing an expression for the general term, we consider the expression $(nq_n - S_n) / q_n$ which is constant for elements of the same section (using the same q). This is easy to see since if S_n and S_{n+1} are in the same section of multiples of q, i.e. $q = q_n = q_{n+1}$, then $S_{n+1} = S_n + q$, so that

$$((n + 1)q - S_{n+1}) / q = (nq + q - (S_n + q)) / q = (nq - S_n) / q.$$

Thus we can define a sequence related to S_n by $v_q = (nq_n - S_n) / q_n$, where n is any subscript from the section of the sequence S_n which uses multiplier q. This sequence (A001840) looks like:

0, 1, 2, 3, 5, 7, 9, 12, 15, 18, 22, 26, 30, 35, 40, 45, 51, 57, 63, 70, ...

This sequence uses an increment of 1 for three terms, then 2 for three terms, then 3 for three terms, and so forth. If we ignore the three term groupings and think about a sequence that increments by 1, then by 2, then by 3, etc., it would have to look basically like $\frac{1}{2}\,q^2$. To get the groupings of three, we can divide this by 3 and use the floor function to obtain Floor(q^2 / 6) which produces the sequence 0, 0, 1, 2, 4, ..., which is not quite right. A slight adjustment allows us to write

$$v_q = \text{Floor}(q(q + 1) / 6).$$

Equating this with the expression defining v_q and solving for S_n gives

$$S_n \quad = \quad q_n n - q_n v_{q(n)} \quad = \quad q_n n - q_n\,\text{Floor}(q_n(q_n + 1) / 6)$$

where

$$q_n = \text{Ceiling}\,(\tfrac{1}{2}\,(-1 + \text{sqrt}(1 + 8n))).$$

This result, however, has been obtained by observing the first few terms of some infinite sequences. It is conceivable that the pattern displayed by the first twenty terms of the sequence v_q might change at some point. (Using a computer program to check up to a q-value of 500,500 revealed no change in the pattern, though.) We still need to prove that the sequences always behave this way so that the formula discovered above gives the correct value for all n.

THE PROOF.

Theorem. Let $\{S_n\}$ be the sequence defined above and let $q_n = q(n) = \text{Ceiling}\,(\tfrac{1}{2}\,(-1 + \text{sqrt}(1 + 8n)))$ so that q_n is the multiplier used in the section of the sequence containing the term S_n. Let $v_q = \text{Floor}(q(q + 1) / 6)$ for $q >= 1$.
Then $S_n = q_n n - q_n v_{q(n)}$ for all $n >= 1$.

Proof (by induction on n). For $n = 1$, $q_1 = 1$ and $S_n = S_1 = 1 = 1\cdot 1 - 1\cdot 0 = q_1\cdot 1 - q_1\cdot v_{q(1)} = q_n\cdot n - q_n\cdot v_{q(n)}$.

Assume the theorem is true for n. If S_n and S_{n+1} are from the same section, i.e. use the same multiplier, then $q_n = q_{n+1} = q$ and $v_{q(n)} = v_{q(n+1)} = v_q$
and so

$$S_{n+1} = S_n + q = qn - qv_q + q = q(n + 1) - qv_q = q_{n+1}(n + 1) - q_{n+1}v_{q+1} ,$$

as required.

If S_n and S_{n+1} are from sections with different multipliers, then $q_{n+1} = q_n + 1 = q + 1$ and S_n was the last term in the section using multiplier q so $n = ½ (q(q + 1))$ and $q = ½ (-1 + \text{sqrt}(1 + 8n))$. S_{n+1} will be the first term larger than S_n which is divisible by $q+1$. The proposed expression for S_{n+1}, $q_{n+1}(n + 1) - q_{n+1}v_{q+1}$, is obviously divisible by q_{n+1} so we only need to show it is the first such number larger than S_n. We consider the difference between this expression and S_n and show it is at most $q + 1$ which will guarantee that our expression gives us S_{n+1}.

Now

$$\begin{aligned} q_{n+1}(n + 1) - q_{n+1}v_{q+1} - S_n &= (q + 1)(n + 1) - (q + 1)v_{q+1} - (qn - qv_q) \\ &= (q + 1) - \left((q + 1)v_{q+1} - qv_q - n\right) \\ &= (q + 1) - \left((q + 1)v_{q+1} - qv_q - ½ (q(q + 1))\right) \end{aligned}$$

This difference will thus be at most $q + 1$ if $(q + 1)v_{q+1} - qv_q - ½ (q(q + 1)) >= 0$.
Let $f(q) = (q + 1)v_{q+1} - qv_q - ½ (q(q + 1)) = (q + 1)\,\text{Floor}\left((q + 1)(q + 2) / 6\right) - q\,\text{Floor}\left(q(q + 1) / 6\right) - ½ (q(q + 1))$.

We consider six cases, the possibilities for q mod 6, and compute (omitting the arithmetic details) the exact value of $f(q)$ in each case:

$$\begin{array}{lll} f(6k) = 0, & f(6k + 1) = 4k + 1, & f(6k + 2) = 2k + 1, \\ f(6k + 3) = 0, & f(6k + 4) = 4k + 3, & f(6k + 5) = 2k + 2. \end{array}$$

In each case, since $k >= 0$, we find $f(q) >= 0$, so that the difference between S_n and the proposed expression for S_{n+1} at most $q + 1$. Thus, this expression, since it is divisible by $q + 1$, does give the first multiple of $q + 1$ which is larger than S_n, i.e. it gives S_{n+1}. The induction is complete and the result proved. •

ADDENDUM.

After reading an initial version of this paper, a colleague, Gerry Hunsberger, suggested another way of generalizing the Connell Sequence. Instead of thinking of the original seqence in terms of even and odd numbers, it is also possible to think of it as "one integer congruent to 1 mod 2, the next two integers congruent to 2 mod 2, the next three integers congruent to 3 mod 2, the next four integers congruent to 4 mod 2, and so forth. This still produces the Connell Sequence but allows for a nice generalization by changing the modulus.

Definition. The Connell k-Sequence, C_k, is defined by taking one integer congruent to 1 mod k, the next two integers congruent to 2 mod k, the next three integers congruent to 3 mod k, the next four integers congruent to 4 mod k, and so forth.

For example, the Connell 3-Sequence would be 1, 2, 5, 6, 9, 12, 13, 16, 19, 22, 23, 26,... (now A033292) and the 8-Sequence would be 1, 2, 10, 11, 19, 27, 28, 36, 44, 52, 53, 61, ... (now A033293).

Within each grouping of terms, the terms increase by an amount k, and when changing from one grouping to the next, the increment is 1. The groupings change after each trianular number. Thus we can consider the n^{th} term as being obtained by adding k for n terms and then subtracting (k-1) for each triangular number less than n. If n is the q^{th} triangular number then q = ½ (-1+sqrt(8n+1)). Since we want to count the number of triangular numbers less than this we replace n by (n-1) and apply the floor function. Thus we find that we can write the general term of the Connell k-Sequence as

$$C_k(n) = kn - (k - 1)\text{Floor}\left(\tfrac{1}{2}\left(-1+\text{sqrt}(8n+1)\right)\right).$$

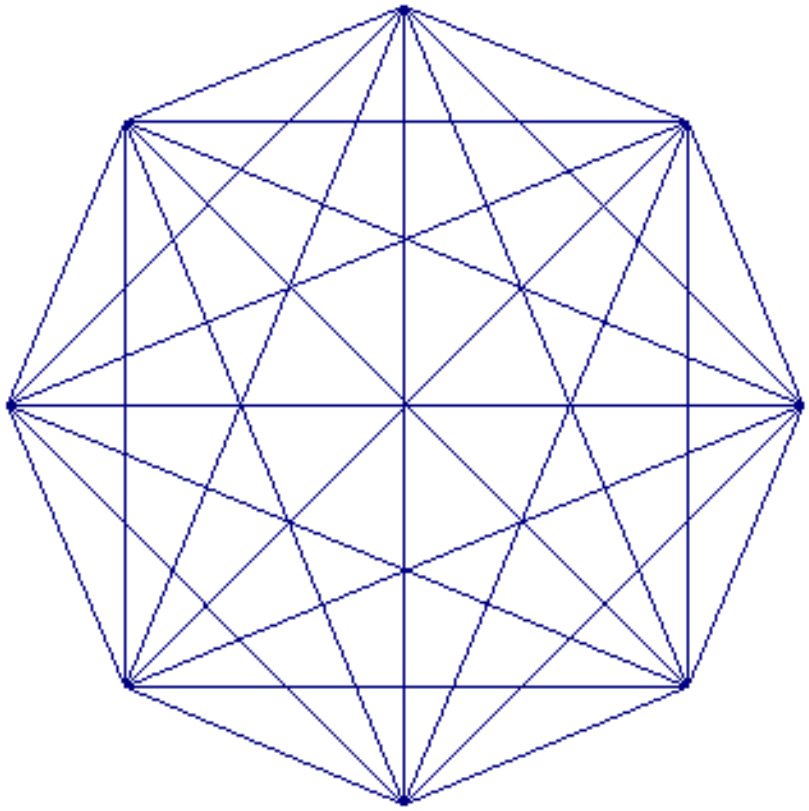
Abstract: We consider the number of triangles formed by the intersecting diagonals of a regular polygon. Basic geometry provides a slight overcount, which is corrected by applying a result of Poonen and Rubinstein [1]. The number of triangles is 1, 8, 35, 110, 287, 632, 1302, 2400, 4257, 6956 for polygons with 3 through 12 sides.

Introduction

If we connect all vertices of a regular N-sided polygon we obtain a figure with $\binom{N}{2} = N(N-1)/2$ lines. For N=8, the figure is:



Careful counting shows that there are 632 triangles in this eight sided figure.

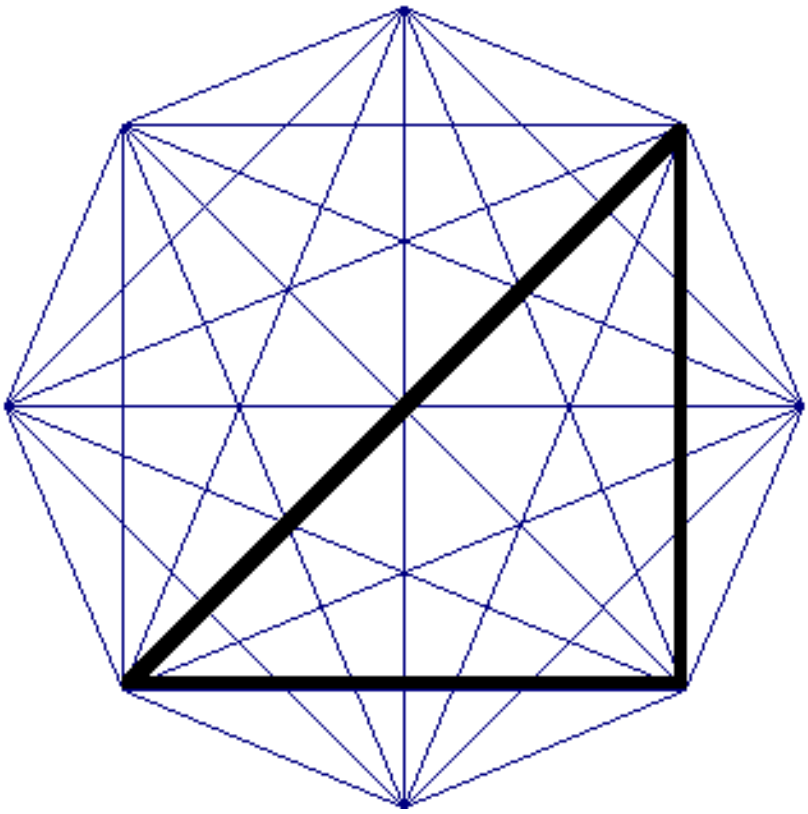
Derivation

All triangles are formed by the intersection of three diagonals at three different points. There are five arrangements of three diagonals to consider. We classify them based on the number of distinct diagonal endpoints. We will directly count the number of triangles with 3, 4 and 5 endpoints (top three figures). We will count the number of *potential* triangles with 6 endpoints, then correct for the false triangles. In each of the following five figures, a sample triangle is highlighted.

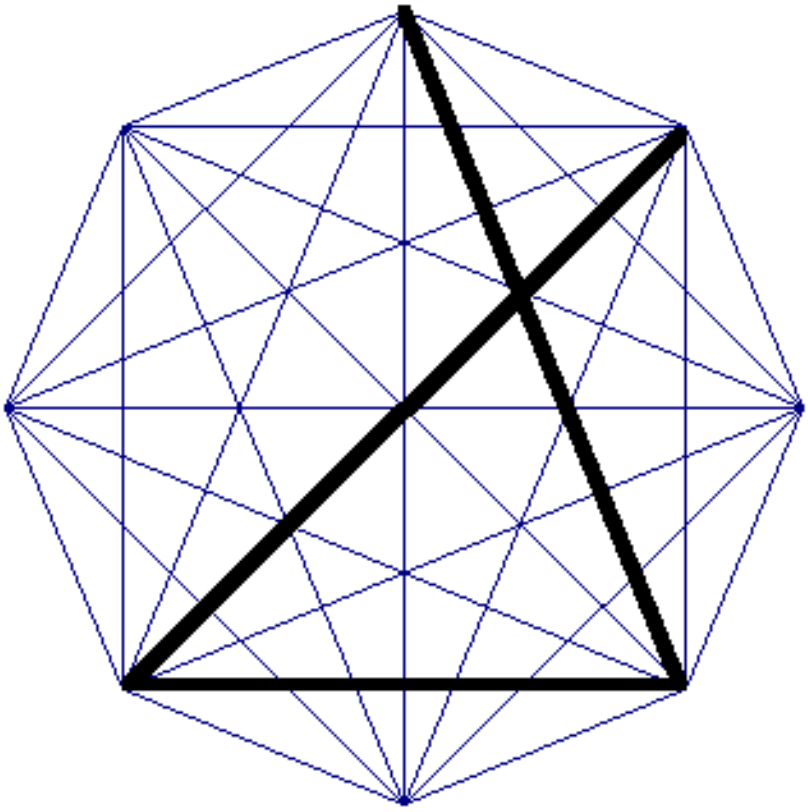
Three, Four and Five Diagonal Endpoints

3 diagonal endpoints. There are 56 such triangles in the figure at left.

The number of triangles formed by diagonals



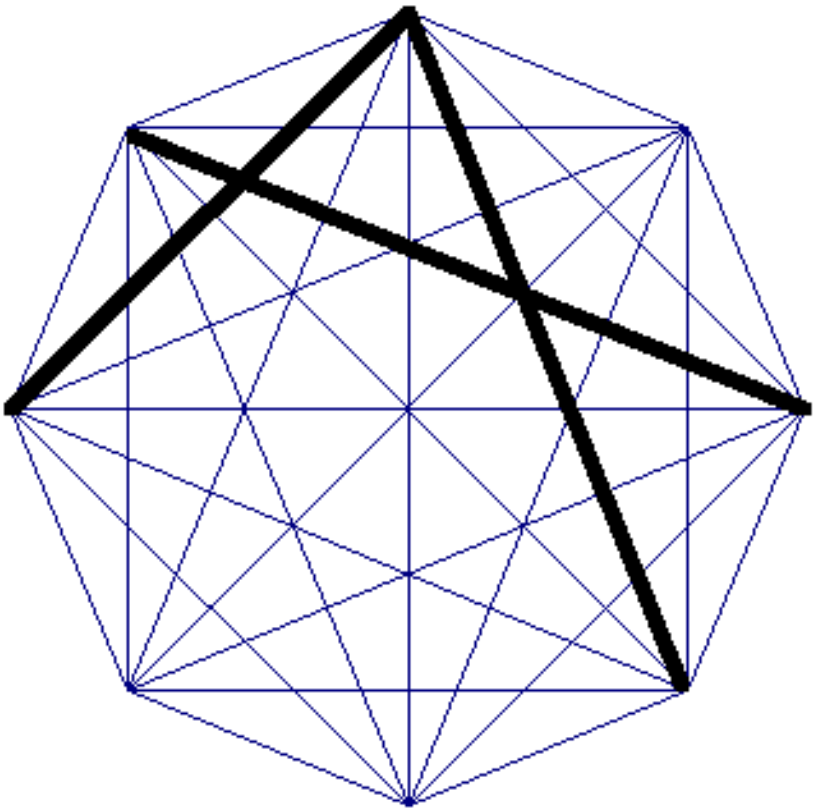
with a total of three endpoints is simply $\binom{N}{3}$.



4 diagonal endpoints. There are 280 such triangles in the figure at left.

There are $\binom{N}{4}$ combinations of the four diagonal endpoints. For each set of four endpoints, there are four triangle configurations.

Thus there are $4\binom{N}{4}$ triangles formed.



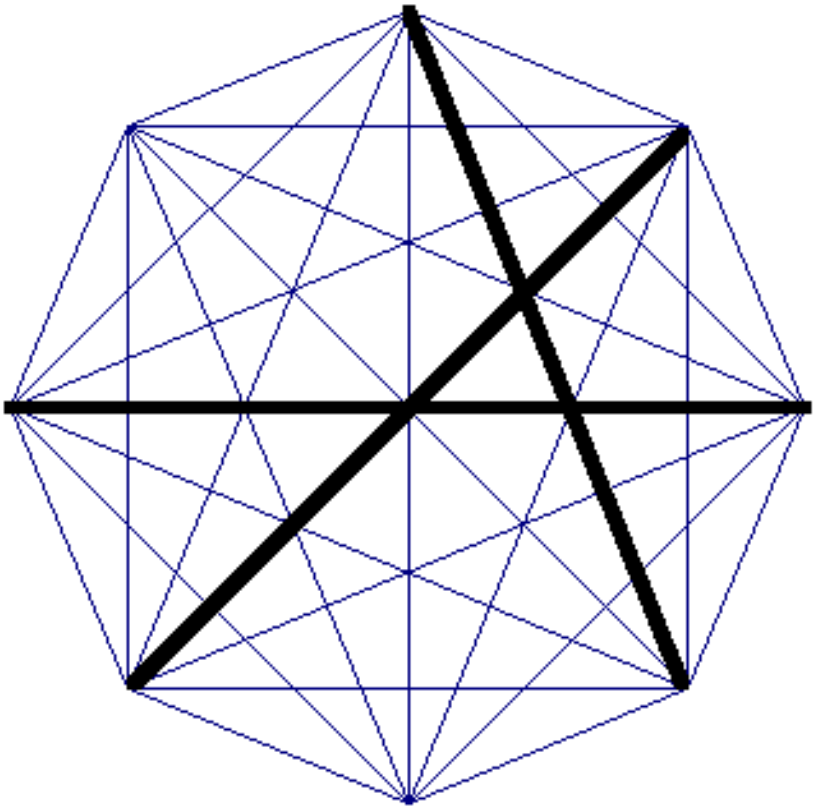
5 diagonal endpoints There are 280 such triangles in the figure at left.

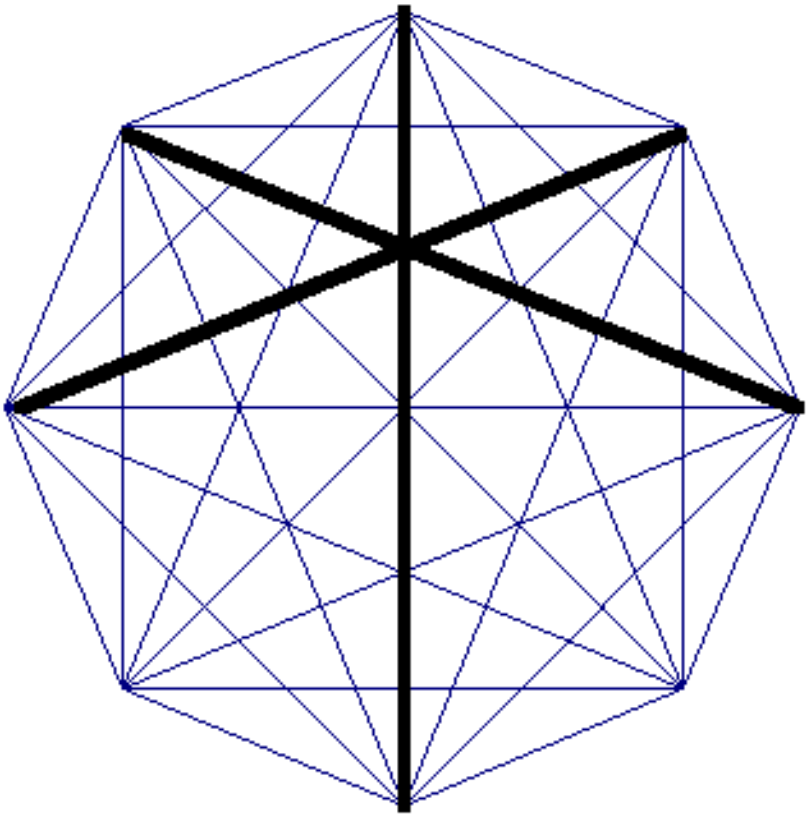
For each of the N vertices of the polygon, there are four other diagonal endpoints which can be placed on the N-1 remaining locations. Thus there are $N\binom{N-1}{4}$ triangles formed. This is equal to $5\binom{N}{5}$.

Six diagonal endpoints

The number of *potential* triangles formed by 6 line segments is $\binom{N}{6}$, since there are 6 segment endpoints to be chosen from a pool of N. Often potential triangles are not created by three overlapping line segments because the line segments intersect at a single point. $\binom{N}{6}$ counts both of the following two situations.

6 diagonal endpoints, resulting in triangle. There are 16 such triangles in the figure at left.





6 diagonal endpoints, false triangle. There are 9 interior intersection points in the figure at left where such false triangles can be formed.

We use a result of [1] to count these false triangles. As in that paper, for a regular N-sided polygon, let $a_m(N)$ denote the number of interior points other than the center where m diagonals intersect. Surprisingly, only the

values m = 2, 3, 4, 5, 6 or 7 may occur. The requisite formulae from [1] are reproduced here:

$$a_3(N)/N = (5N^2 - 48N + 76)/48 \bullet \delta_2(N) + 3/4 \bullet \delta_4(N) + (7N - 38)/6 \bullet \delta_6(N)$$
$$-8 \bullet \delta_{12}(N) - 20 \bullet \delta_{18}(N) - 16 \bullet \delta_{24}(N) - 19 \bullet \delta_{30}(N) + 8 \bullet \delta_{42}(N)$$
$$+68 \bullet \delta_{60}(N) + 60 \bullet \delta_{84}(N) + 48 \bullet \delta_{90}(N) + 60 \bullet \delta_{120}(N) + 48 \bullet \delta_{210}(N)$$

$$a_4(N)/N = (7N - 42)/12 \bullet \delta_6(N) - 5/2 \bullet \delta_{12}(N) - 4 \bullet \delta_{18}(N) + 3 \bullet \delta_{24}(N)$$
$$+6 \bullet \delta_{42}(N) + 34 \bullet \delta_{60}(N) - 6 \bullet \delta_{84}(N) - 6 \bullet \delta_{120}(N)$$

$$a_5(N)/N = (N - 6)/4 \bullet \delta_6(N) - 3/2 \bullet \delta_{12}(N) - 2 \bullet \delta_{24}(N) + 4 \bullet \delta_{42}(N)$$
$$+6 \bullet \delta_{84}(N) + 6 \bullet \delta_{120}(N)$$

$$a_6(N)/N = 4 \bullet \delta_{30}(N) - 4 \bullet \delta_{60}(N)$$

$$a_7(N)/N = \delta_{30}(N) + 4 \bullet \delta_{60}(N)$$

where $\delta_m(N) = 1$ if $N \equiv 0 (\mathrm{mod}\, m)$, 0 otherwise.

If there are K line segments that intersect at one common point, where K>2, there are $\binom{K}{3}$ false triangles corresponding to that point. Thus the correction term for false triangles is

$$a_3(N)\binom{3}{3} + a_4(N)\binom{4}{3} + a_5(N)\binom{5}{3} + a_6(N)\binom{6}{3} + a_7(N)\binom{7}{3} + \delta_2(N)\binom{N/2}{3}$$

where the last term represents the contribution of the center point for even N. The correction is 0 for odd N. The number of triangles formed by line segments with six endpoints on the polygon is then:

$$\binom{N}{6} - \left(a_3(N)\binom{3}{3} + a_4(N)\binom{4}{3} + a_5(N)\binom{5}{3} + a_6(N)\binom{6}{3} + a_7(N)\binom{7}{3} + \delta_2(N)\binom{N/2}{3}\right)$$

Result

The table below summaries the results for $N \leq 20$. These values were checked through use of a computer program performing an exhaustive search.

N	Triangles with 3 diagonal endpoints	Triangles with 4 diagonal endpoints	Triangles with 5 diagonal endpoints	Triangles with 6 diagonal endpoints	Total Number of Triangles
3	1	0	0	0	**1**

The sequence formed by the total number of triangles was studied by the late Victor Meally in the 1960's,

although it appears he did not find our formula for the *N*-th term. This is sequence A006600 in the On-Line Encyclopedia of Integer Sequences.

To summarize the final result, the number of triangles generated by intersecting diagonals of an *N*-regular polygon is:

$$\binom{N}{3} + 4\binom{N}{4} + 5\binom{N}{5} + \binom{N}{6}$$
$$- (a_3(N)\binom{3}{3} + a_4(N)\binom{4}{3} + a_5(N)\binom{5}{3} + a_6(N)\binom{6}{3} + a_7(N)\binom{7}{3} + d_2^g(N)\binom{N/2}{3})$$

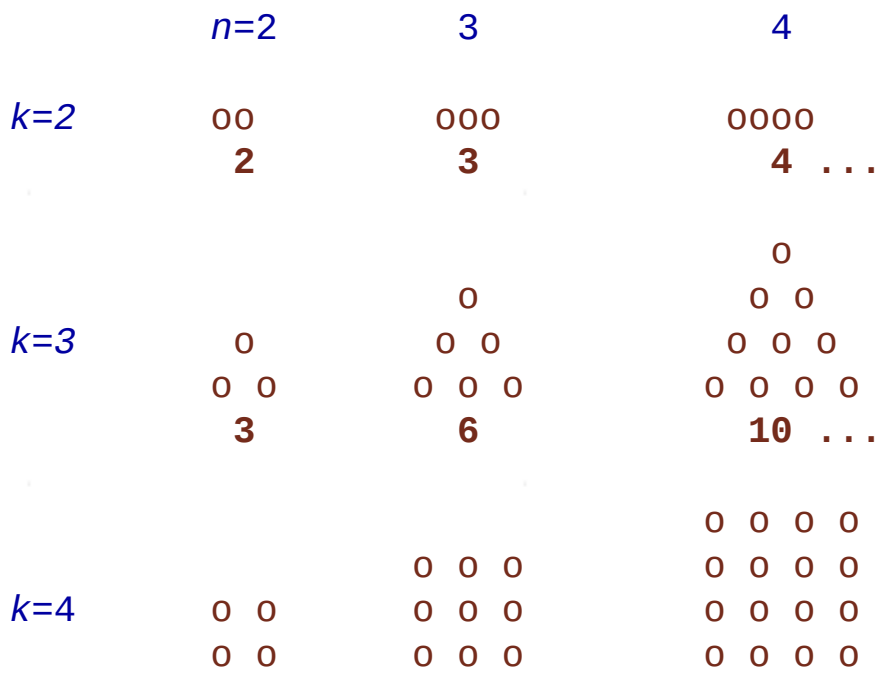
On Repdigit Polygonal Numbers

Mike Keith
4100 Vitae Springs Road
Salem, OR 97306
Email address: domnei@aol.com

Abstract: We consider the problem of determining which polygonal numbers are repdigits (numbers consisting of a single repeated digit). An efficient algorithm for finding repdigit polygonal numbers is presented and used to provide a complete characterization of all 1526 such numbers with 50 or fewer digits. Several other new and intriguing integer sequences (such as the sequence of so-called primitive solutions) are also introduced.

1. Introduction

The *polygonal numbers* are illustrated in the figure below. The *n*th *k*-sided polygonal number, $P(k,n)$, is the number of counters that can be arranged into a *k*-sided polygon with *n* counters along each side.



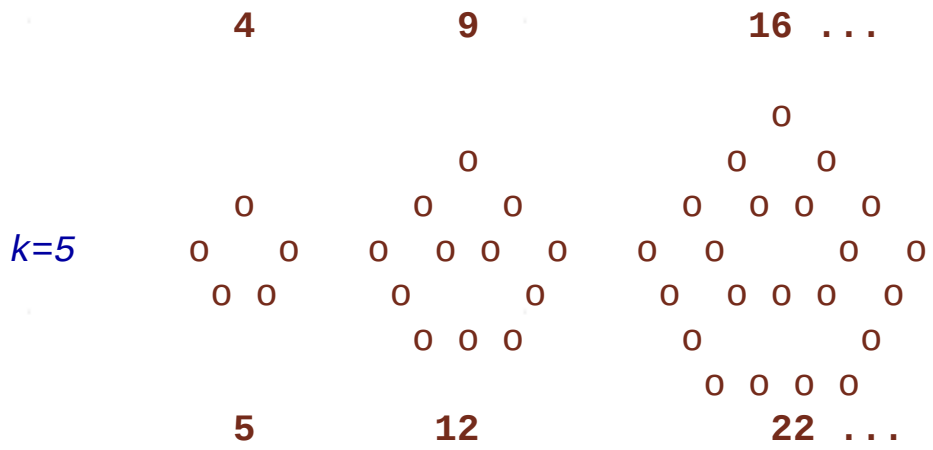


Figure 1. The first few polygonal numbers

A formula for $P(k,n)$ is:

$$P(k,n) = n((k-2)(n-1) + 2)/2 \qquad (n>=2 \text{ and } k>=2) \qquad (1)$$

A *repdigit* is a number, like 3 or 55 or 999999, consisting of repetitions of a single digit. Some polygonal numbers are also repdigits, such as $P(5,4)=22$ shown in Figure 1, or more dramatically

$$P(8925662618878671, 387) = 666666666666666666666.$$

In this paper we consider some properties of these *repdigit polygonal* (RP) numbers as well as some new integer sequences which result from their study.

2. Finding RP Numbers, and the Combination Sequence

The primary problem is to determine which polygonal numbers are also repdigits. The converse is easy - every repdigit number is trivially a polygonal number, because every integer r is equal to both $P(2,r)$ and $P(r,2)$, as can be seen by the fact that the first row and column of Figure 1 are just the integers in order. However, nontrivial representations are also possible, as shown by (see Figure 1)

$$P(2,22) = P(5,4) = P(22,2) = 22$$

or

$$P(2,666) = P(3,36) = P(46,6) = P(223,3) = P(666,2) = 666.$$

We define the *combination number* of a given repdigit r, $c(r)$, to be the number of pairs n, k such that $P(n,k) = r$. The above examples show that $c(22)=3$ and $c(666)=5$. The *combination sequence* is the

sequence of combination numbers pertaining to the successive repdigits (which are 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 22, 33, 44, 55, 66, 77, 88, 99, 111, 222, 333, etc., sequence A010785 in the *On-Line Encyclopedia of Integer Sequences*).

Here is an efficient procedure for computing the combination number of a given repdigit. Every repdigit is just some decimal digit, d, times a *repunit number* (a number of the form 111...1). We denote the repunit with m decimal digits by R_m. Then equation (1) becomes

$$dR_m = n((k-2)(n-1) + 2)/2$$

Solving for k, we get

$$k = ((2dR_m)/n + 2n - 4)/(n-1)$$

Denote the quotient $(2dR_m)/n$ by the symbol q. For a given R_m to be a polygonal number, we see that it is necessary and sufficient that the two following conditions hold:

$$2dR_m = 0 \pmod{n}, \qquad (a)$$

$$q + 2n - 4 = 0 \pmod{n-1}. \qquad (b)$$

Condition (a) is required for q to be an integer, and (b) is required for k to be an integer. Note that (b) can be rewritten as

$$q = 2 \pmod{n-1}. \qquad (b')$$

Condition (a) means that *the only possible values of n* are the divisors of $2dR_m$. We must therefore factorize R_m. Fortunately, the prime factorizations of the repunits can be readily obtained from a number of sources, or calculated easily (at least for the first hundred or so repunits) using modern factorization algorithms. We assume that a table of repunit factorizations is provided. We can now find all (k,n) pairs such that $P(k,n)$ equals a given repdigit number dR_m by the following simple procedure:

```
Put all the prime factors of R(m) in a list.
Adjoin 2 and the prime factors of d.
Form all possible divisors n of 2*d*R(m) by taking all
 combinations of primes from this list.
```

```
For each trial divisor n, compute q.
If q = 2 mod (n-1), this is a success: (k,n) is an RP
number.
```

This algorithm must be programmed in a language that supports arbitrary-precision arithmetic. We used UBASIC, and were able to find all repdigit polygonal numbers with 50 or fewer decimal digits in a couple of hours on a home PC. From this we can tabulate the first 500 values of the combination sequence (A033618), which are as follows:

	d								
	1	2	3	4	5	6	7	8	9
m									
1	0	1	2	2	2	3	2	2	3
2	2	3	3	2	4	5	2	3	3
3	4	3	4	3	4	5	3	3	3
4	3	2	3	3	3	6	3	2	3
5	2	3	3	3	3	4	2	3	3
6	7	3	4	3	4	5	4	3	4
7	2	2	3	3	3	4	3	3	3

50	3	4	3	2	3	6	2	3	3

Table 1. c(r), the number of ways of expressing each repdigit, $r = dR_m$, as a polygonal number.

Every term in this sequence (after the first two) is at least 2, since every repdigit number r equals both $P(r,2)$ and $P(2,r)$. The largest term so far in this sequence is the (unique) 9 at m=36, d=1. This says that there are 9 different ways of representing the number 11111 11111 11111 11111 11111 11111 11111 1 as a polygonal number. The value 8 does not yet occur, although presumably it will eventually. The average of all the terms in the sequence so far is close to 3 (about 3.06).

Here are a few related sequences. Summing up each row, we obtain *the number of polygonal numbers which are m-digit repdigits* (for m=1, 2, 3, ..., A033702):

```
17 27 32 28 26 37 26 29 35 28 27 38 29 29 34 33 26 37 26 31 35 27 26 36 27
31 36 29 28 37 26 30 35 27 27 41 26 31 34 29 27 38 27 31 40 29 27 37 28 29
```

The partial sums of *this* sequence give *the number of polygonal numbers which are repdigits with m or fewer digits* (A033703):

```
RPN(m) = 17   44   76  104  130  167  193  222  257  285
 312  350  379  408  442  475  501  538  564  595
 630  657  683  719  746  777  813  842  870  907
 933  963  998 1025 1052 1093 1119 1150 1184 1213
1240 1278 1305 1336 1376 1405 1432 1469 1497 1526
```

In particular, there are precisely 1526 distinct repdigit polygonal numbers with 50 or fewer digits.

3. Primitive Repdigit Polygonal Numbers

So far we have not actually displayed a listing of the 1526 repdigit polygonal numbers with 50 or less digits. The reason for this is that we can describe these numbers using a much smaller list, by recognizing that many of these RP numbers are related.

For example, consider:

$P(2,3) = 33$
$P(12,3) = 333$
$P(112,3) = 3333$
etc.

and

$P(5,4) = 22$
$P(3705,4) = 22222$
$P(3703705,4) = 22222222$
etc.

In both cases, as we shall see below, there is an infinite sequence of RP numbers, where n remains constant, k steadily increases and the repdigit number has the same base digit d but gets p digits longer at each step. We refer to p as the *period* of the infinite RP number sequence.

In turns out that almost every repdigit polygonal number is a member of one of these infinite sequences. We call the first term in such a sequence the *primitive* RP number. We distinguish between two types: a *simple* primitive RP number, in which k=2 or n=2, and a *fancy* primitive number (the rest). The reason for this distinction is that all the simple primitives are obvious (since the k=2 and n=2 polygonal numbers are just the integers in order), and hence the fancy primitives are the only ones that really need to be enumerated.

Before enumerating all the primitive RP numbers less than 10^{50}, we first explain why these infinite sequences of solutions occurs.

Suppose we have *any* RP number, which as we have seen must satisfy conditions (a) and (b'). Also, n is a product of certain prime divisors of $2dR_m$. In general n will consist of zero or more factors of $2d$ combined with zero or more factors of R_m.

Lemma 1: If R_m is the smallest repunit divisible by a prime f, then R_{cm} is also divisible by f, for all $c >= 1$.

Proof: By induction on *c*. If R_{cm} is divisible by *f*, then so is $R_{(c+1)m}$, because

$$R_{(c+1)m} = 10^m R_{cm} + R_m$$

and both terms on the right side are divisible by *f* (by the induction hypothesis).

For example, the 3rd repunit, 111, factors as 3 x 37. Both of these factors are present in the 6th repunit, 111111 (which = 3 x 7 x 11 x 13 x 37), the 9th repunit 111111111 (which = 3 x 3 x 37 x 333667), and so on.

Consider now our RP number, for which *n* contains a subset of the prime factors of the repunit R_m. Although *m* may not be the smallest index in which each of these prime factors occurs, we know from the lemma that each prime factor in this subset will occur among the higher repunits with *some* period. Define P_{rep} to be the LCM of all these periods. Then it must be the case that every P_{rep}-th repunit after this one is divisible by *n*, since each of these contains the prime factors needed for *n* to divide it evenly.

In summary: if we start from a given RP number and form larger ones in which *d* and *n* remain the same and the length of the repunit increases in steps of P_{rep}, *every one of these will satisfy condition* (*a*).

Example: consider *P*(41139,74)=111111111. Since *n* = 74 = 2 x 37, and the 2 can be obtained from 2*d*, the only repunit factor *n* contains is 37. We know from the previous example that 37 occurs as a prime factor of every 3rd repunit (because the lowest repunit in which it appears is R_3); therefore P_{rep} = 3. This means that 111111111111 and every 3rd repunit thereafter will be divisible by 37, and will therefore satisfy condition (*a*). For instance, 2 x 111111111111 is exactly divisible by 74.

What about condition (*b'*)?

We have a series of repunits which satisfy condition (*a*): $r_0 = R_m$, $r_1 = R_{m+Prep}$, $r_2 = R_{m+2Prep}$, etc., and at the first step condition (*b'*) is satisfied: $q = 2dr_0/n = 2 \bmod n\text{-}1$. We ask: what is the sequence of *q* values (q_0, q_1, q_2, ...) that correspond to the repdigits r_0, r_1, r_2, ...? To answer this, note that each repunit in the sequence is related to the previous one by

$$r_i = 10^{Prep} r_{i-1} + R_{Prep},$$

i.e.

$$(2dr_i)/n = (2d10^{Prep}r_{i-1})/n + (2dR_{Prep})/n ,$$

or

$$q_i = q_{i-1}10^{Prep} + q_0 \bmod 10^{Prep}$$

For (*b'*) to be satisifed we need $q_i = 2 \bmod n\text{-}1$ for some larger *i*. This will be the case (and there will be an infinite sequences of cases for which it is true) if the following condition holds:

Ring Period Condition: Working in the ring of integers mod *n*-1, start with the value 2 and successively apply the linear recurrence $q_i = aq_{i-1} + b$, where $a = 10^{Prep} \bmod n\text{-}1$ and $b = (q_0 \bmod 10^{Prep}) \bmod n\text{-}1$. If the sequence of values q_0 (= 2) -> q_1 -> q_2 -> ... eventually returns to the value 2 (which means it satisfies condition (*b'*)) then the primitive repdigit polygonal number under consideration generates an infinite sequence of RP numbers.

We refer to the period with which 2 repeats in the sequence of *q*'s as the *ring period* P_{ring}. Because the sequence of *q*'s is itself spaced with a period of P_{rep} within the repdigits, the full period with which additional RP numbers appear beyond a primitive one is the product of these two periods: $p = P_{rep}P_{ring}$.

Continuing the previous example, we may now determine the sequence of RP numbers generated by the primitive solution *P*(41139,74)=111111111, for which $P_{rep} = 3$. We compute $a = 10^3 \bmod 73 = 51$ and $b = ((2 \times 111111111)/74 \bmod 10^3) \bmod 73 = 2$. Starting with 2 and applying the function $51x + 2$ iteratively, we produce:

starting value:		2
51*2+2 =	104 =	31 mod 73
51*31+2 =	1583 =	50 mod 73
51*50+2 =	2552 =	70 mod 73
51*70+2 =	3572 =	68 mod 73
51*68+2 =	3470 =	39 mod 73
51*39+2 =	1991 =	20 mod 73
51*20+2 =	1022 =	0 mod 73

51*0 +2 = 2 = 2 mod 73

so P_{ring} = 8. The full period for this primitive solution is therefore 3 x 8 = 24. We obtain the following sequence of RP numbers:

P(41139,74) = 111111111
P(411370274383973014110000041139,74) = 111111111111111111111111111111111
etc.

where each repdigit in the sequence (and, consequently, each value of *k*) is 24 digits longer than the previous one.

We can now concisely describe all RP numbers of 50 digits or less. First, take all those which are generated by the simple primitive solutions with *k*=2 and *n* equal to some repdigit number. Here are the periods of the small simple primitive solutions:

	Value of *d*								
m	1	2	3	4	5	6	7	8	9
1			1	3	1	1	3	6	**
2	2	6	**	42	54	6	18	84	42
3	6	48	123	663	69	18	96	2658	498
4	12	2220	336	2220	2776	420	972	17772	1428
5	20	36990	480	31710	33810	495	4860	49380	3205

Table 2. Periods of the simple primitive RP numbers 3,4,5,...99999 with *k*=2.

All of the larger simple primitive solution have a period of at least 498, and so are not relevant for RP numbers with 50 digits or less. There is one exception: the *d*=1 primitives, all of which (as can be seen from the table) have relatively small periods. In fact, it is easy to show that those solutions have a period of exactly *m*(*m*-1).

In addition to these simple primitives, we also have to consider the remaining simple primitives, which are simply those of the form *k=d*, *n*=2, *repdigit=d*, and all the RP numbers generated by these (which are of the form *k=ddd...d*, *n*=2, *repdigit=ddd...d*).

Finally, take all those generated by the fancy primitive solutions. Table 3 below gives the complete list of fancy primitive RP numbers of 50 digits or less (A033704 and A033705) with their periods.

Table 3. All fancy primitive repdigit polygonal numbers less than 10^{50}.

As an example, we derive the entry in Table 1 which says that there are 9 manifestations of r = 11111 11111 11111 11111 11111 11111 11111 1 (36 1's) as an RP number. First, there is the simple primitive solution $(k,n) = (r, 2)$. Looking at Table 2, we see that the simple primitive solution (11,2) has period 2,

so it generates solutions with any even number of digits, including 36. The 6-digit simple primitive solution (111111,2), which is just beyond the end of Table 2, has, as described earlier, period 6 x 5 = 30, so it also generates a 36-digit solution. There is also the obvious simple primitive solution (2, *r*).

To complete the list, look in Table 3 for RP numbers consisting of 1's with the correct period so that a 36-digit solution can be generated. We find five possibilities: (38,3) and (9,6) with length 3 and period 3, (531,21) with length 6 and period 6, (131,42) with length 6 and period 30, and the *n*=143 36-digit solution. Thus all nine solutions can be found from Tables 2 and 3.

Two of the simple primitive solutions (the ones marked with **: (2,9) and (2,33)) in Table 2 do not have finite ring periods, and so do not generate any additional solutions. For example, for (2,9) the recurrence gets stuck in a cycle of length one at the value 6. Are there other solutions with this property?

Note from Table 3 that one of the "fancy" things about the fancy primitives is the progression of *k* values, which also form an interesting sequence, A033706 (as do the values of *n*, A033707):

> 3, 4, 5, 3, 3, 16, 38, 9, 75, 11, 149, 186, 3, 260, 297, 9, 1589, 531, 131, 1475, 514, 41139, 21604940, ...

It has been noted since 1979 (see [2]) that all primitive RP numbers with *k*>2 tend to have large *k* and small *n*. (If a primitive solution has this property, then all RP numbers derived from it will also. So this is equivalent to saying that *all* RP numbers with *k*>2 tend to have large *k* and small *n*.)

In particular, the following conjecture, made in [2], is now strongly supported by the numerical evidence in Table 3 (although we still do not have a proof).

Conjecture. The only RP numbers with $k > 2$ and $n > k$ are $P(3,10)$, $P(3,11)$, $P(3,36)$, and $P(9,44)$.

A related conjecture comes from defining the *wickedness* of an RP number to be the value of *n/k*.

Conjecture. The most wicked RP number with k>2 is the "Beast number", 666 = (3,36), with $n/k = 12$.

Another remarkable solution in Table 3 is (8944083, 27302) = 3333333333333333, whose *k* value is the largest among the fancy primitives so far.

Finally, define a *simple RP number* to be one generated from a simple (or trivial) primitive solution, and a *fancy RP number* to be one generated from a fancy primitive solution. What is the distribution of simple versus fancy RP numbers? Here are the two sequences (number of RP numbers of *m* digits, A033708, and their partial sums, A033709) for simple:

Numbers with exactly m digits:

```
15 21 21 24 21 22 24 24 22 24 21 22 24 24 22 25 21 22 24 25 23 24
21 22 25
24 22 25 21 22 24 24 22 24 21 23 24 25 23 25 21 22 24 26 23 24 21
22 25 24
```

Numbers with m or fewer digits:

```
  15   36   57   81  102  124  148  172  194  218
 239  261  285  309  331  356  377  399  423  448
 471  495  516  538  563  587  609  634  655  677
 701  725  747  771  792  815  839  864  887  912
 933  955  979 1005 1028 1052 1073 1095 1120 1144
```

and fancy (A033710 and A033711) RP numbers :

Numbers with exactly m digits:

```
 2  6 11  4  5 15  2  5 13  4  6 16  5  5 12  8  5 15  2 6 12  3
5 14  2
 7 14  4  7 15  2  6 13  3  6 18  2  6 11  4  6 16  3  5 17  5  6
15  3  5
```

Numbers with m or fewer digits:

```
   2    8   19   23   28   43   45   50   63   67
  73   89   94   99  111  119  124  139  141  147
 159  162  167  181  183  190  204  208  215  230
 232  238  251  254  260  278  280  286  297  301
 307  323  326  331  348  353  359  374  377  382
```

As can be seen from these sequences, there are many fewer fancy RP numbers than simple ones. Of the 1526 RP numbers with 50 digits or less, only 382 (= 25.03%) are fancy ones.

Abstract: This paper considers combinatorial interpretations for two triangular recurrence arrays containing the Schröder numbers s_n = 1, 1, 3, 11, 45, 197, ... and r_n = 1, 2, 6, 22, 90, 394, ... , for n = 0, 1, 2, ... These interpretations involve the enumeration of constrained lattice paths and bicolored parallelogram polyominoes, called *zebras*. In addition to two recent inductive constructions of zebras and their associated generating trees, we present two new ones and a bijection between zebras and constrained lattice paths. We use the constructions with generating function methods to count sets of zebras with respect to natural parameters.

Abstract: The terms of A000278, the sequence defined by $h_0=0$, $h_1=1$, and $h_{n+2}=h_{n+1}+h_n^2$, count the trees in certain recursively defined forests. We show that for n large, h_n is approximately $A^{\mathrm{sqrt}(2)^n}$ for n even and h_n is approximately $B^{\mathrm{sqrt}(2)^n}$ for n odd, with A,B > 1 and A not equal to B, and we give estimates of A and B: A is 1.436 ± .001 and B is 1.452 ± .001. The doubly exponential growth of the sequence is not surprising (see, for example, [AS]) but the dependence of the growth on the parity of the subscript is more interesting. Numerical and analytical investigation of similar sequences suggests a possible generalization of this result to a large class of such recursions.

Asymptotics

We study the growth of

$$h_{n+2} = h_{n+1} + (h_n)^2 \qquad (1)$$

as $n \to \infty$.

The sequence $\{h_n\}$ is bounded by double the square of its translate:

Lemma 1. If $n \geq 1$, then $0 < h_n < h_{n+1} < 2(h_n)^2$.

Lemma 1 If $n \geq 1$, then $0 < h_n \leq h_{n+1} \leq 2(h_n)^2$.

Proof This is true for $n = 1$. Since the sequence is increasing, $h_n \leq h_{n+1}$ always, and $h_{n+2} = h_{n+1} + (h_n)^2 \leq (h_{n+1})^2 + (h_{n+1})^2 = 2(h_{n+1})^2$. ■

Rewrite (1) in the following way for $n \geq 1$:

$$h_{n+2} = h_{n+1} + (h_n)^2 = (h_n)^2 \overbrace{\left(1 + \frac{h_{n+1}}{(h_n)^2}\right)}^{\alpha_n}.$$

The preceding lemma shows that $1 \leq \alpha_n \leq 3$ if $n \geq 1$. Then

$$h_{n+2} = (h_{n-2})^1(\alpha_{n-2})^2\alpha_n = (h_{n-1})^8(\alpha_{n-1})^1(\alpha_{n-2})^2\alpha_n = \ldots$$

which gives $h_{2n} = \prod_{j=0}^{n-1}(\alpha_{2n-2j-2})^{2^j}$ if n is a positive integer and α_0 is defined to be 1. More algebra is enlightening, beginning with reversing the product index:

$$h_{2n} = \prod_{j=0}^{n-1}(\alpha_{2j})^{2^{(n-j-1)}} = \exp\left(\sum_{j=0}^{n-1}\log\left((\alpha_{2j})^{2^{(n-j-1)}}\right)\right) = \exp\left(2^n\sum_{j=0}^{n-1}\frac{1}{2^{j+1}}\log\alpha_{2j}\right)$$

$$= \left(\exp\left(\sum_{j=0}^{n-1}\frac{1}{2^{j+1}}\log\alpha_{2j}\right)\right)^{2^n} = \left(\exp\left(\sum_{j=0}^{n-1}\frac{1}{2^{j+1}}\log\alpha_{2j}\right)\right)^{(\sqrt{2})^{2n}}.$$

Therefore if A is defined by requiring

$$\log A = \sum_{j=0}^{\infty}\frac{1}{2^{j+1}}\log\alpha_{2j}, \qquad (2)$$

it seems plausible to expect that $h_{2n} \approx A^{(\sqrt{2})^{2n}}$.

A similar analysis for odd integers incorporates the initial condition $h_1 = 1$ and uses the formula $h_{2n+1} = \prod_{j=0}^{n-1}(\alpha_{2n-2j-1})^{2^j}$. This leads to defining B by the equation

$$\log B = \frac{1}{\sqrt{2}}\sum_{j=0}^{\infty}\frac{1}{2^j}\log\alpha_{2j+1}. \qquad (3)$$

$$\log B = \frac{1}{\sqrt{2}} \sum_{j=0}^{\infty} \frac{1}{2^{j+1}} \log \alpha_{2j+1}\,, \qquad (3)$$

and to the expectation that $h_{2n+1} \approx B^{(\sqrt{2})^{2n+1}}$.

Lemma 2 The series of non-negative constants defined in (2) and (3) converge, and all partial sums of the first N terms of each of them are within $\frac{\log 3}{2^N}$ of the actual sums. By considering partial sums for $N = 15$, we obtain an estimate for A (respectively, B) which is 1.436 (respectively, 1.451) with error less than .001.

Proof Since $0 \le \log \alpha_n \le \log 3$ the convergence of the geometric series $\sum \frac{1}{2^j}$ implies the convergence of both series shown. Then infinite tails of both series can be overestimated by $\frac{\log 3}{\text{powers of } 2}$. The numerical results are obtained by direct calculation. ■

Theorem 1 $\lim_{n\to\infty} \frac{h_{2n}}{A(\sqrt{2})^{2n}} = 1$ and $\lim_{n\to\infty} \frac{h_{2n+1}}{B(\sqrt{2})^{(2n+1)}} = 1$

Proof Consider the first limit. Unravel some algebra via

$$\frac{h_{2n}}{A(\sqrt{2})^{2n}} = \frac{\exp\left(2^n \sum_{j=0}^{n-1} \frac{1}{2^{j+1}} \log \alpha_{2j}\right)}{\left(\exp\left(\sum_{j=0}^{\infty} \frac{1}{2^{j+1}} \log \alpha_{2j}\right)\right)^{2^n}} = \exp\left(-\sum_{j=n}^{\infty} 2^{n-j-1} \log \alpha_{2j}\right)$$

to discover that the desired result will follow an estimate which shows that the series $\sum_{j=n}^{\infty} 2^{n-j-1} \log \alpha_{2j} = 2^n \sum_{j=n}^{\infty} 2^{-j-1} \log \alpha_{2j}$ approaches 0 as $n \to \infty$. The estimation needs to be finer than what $0 \le \log \alpha_{2j} \le \log 3$ can provide.

First, $0 \le \log \alpha_j \le \frac{h_{j+1}}{(h_j)^2}$ because $\log(1+x) \le x$ for $x \ge 0$. The series (2) and (3) both have positive terms. Since $h_{2j} = \exp\left(2^j \sum_{k=0}^{j-1} \frac{1}{2^{k+1}} \log \alpha_{2k}\right)$, we know by Lemma 2 that for $j \ge 15$, $e^{2^j \log(1.4)} \le h_{2j} \le e^{2^j \log A}$. Similarly,

for $j \ge 15$, $e^{2^{(j+.5)} \log(1.4)} \le h_{2j+1} \le e^{2^{(j+.5)} \log B}$. If $C = \max(A, B)$, $C < 1.46$ and $C^{\sqrt{2}} < 1.46^{1.42} < 1.72$. We have

$C < 1.46$ and $C^{\sqrt{2}} < 1.46^{1.42} < 1.72$. We have

$$0 \le \frac{h_{j+1}}{(h_j)^2} \le \frac{\exp\left(2^{.5j+.5}\log C\right)}{[\exp(2^{.5j}\log(1.4))]^2} \le \frac{\left(C^{\sqrt{2}}\right)^{\sqrt{2}^j}}{\left(1.4^{\sqrt{2}^j}\right)\left(1.4^{\sqrt{2}^j}\right)} < \left(\frac{1.72}{(1.4)^2}\right)^{\sqrt{2}^j} < .9^{\sqrt{2}^j}$$

which allows the series to be estimated easily. If $j \ge 6$, then $\sqrt{2}^j > 1.4j$ and the following estimate is valid:

$$2^n \sum_{j=n}^{\infty} 2^{-j-1} \log \alpha_{2^j} < 2^n \sum_{j=n}^{\infty} 2^{-j-1} \left(.9^{\sqrt{2}^j}\right)$$

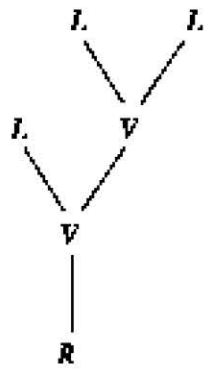
$$< 2^{n-1} \sum_{j=n}^{\infty} 2^{-j} (.9^{1.4j}) = \frac{.5}{1 - .5(.9)^{1.4}} (.9^{1.4})^n$$

This overestimate certainly approaches 0 rapidly, so the first limit in the theorem is verified. The second, for odd integers, follows in a similar fashion. ■

The proof above certainly doesn't use all the information present. In fact, the convergence to the limits is extremely rapid, and very sharp error estimates can be made. A result similar to theorem 1 with similar error estimates can be proved for any non-negative initial conditions. Different initial conditions give rise to different growth constants. The link between the pair of initial conditions and the pair of growth constants for this recurrence has been shown to be a real analytic mapping with further interesting properties. See [GN].

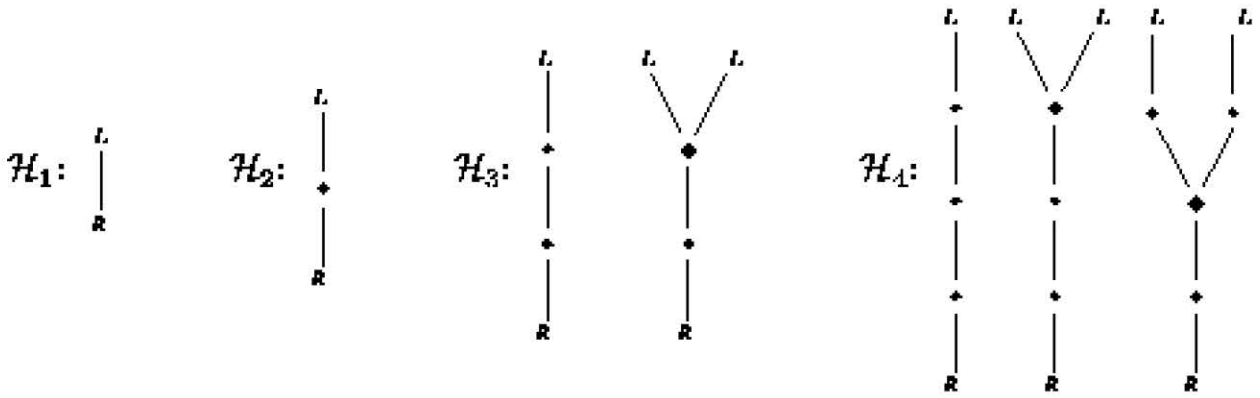
Counting the trees in a forest

A graph is a set of vertices together with a set of edges where the edges connect pairs of distinct vertices. A vertex connected by an edge is called *incident* with that edge. A *tree* here will be a connected graph without cycles, which are closed paths of edges. The number of edges a vertex is incident with is called the *degree* of the vertex. A *rooted tree* has one distinguished vertex with degree 1. The root vertex will be labeled *R*. Any other vertices of degree 1 in a rooted tree are called *leaves* and will be labeled *L*.

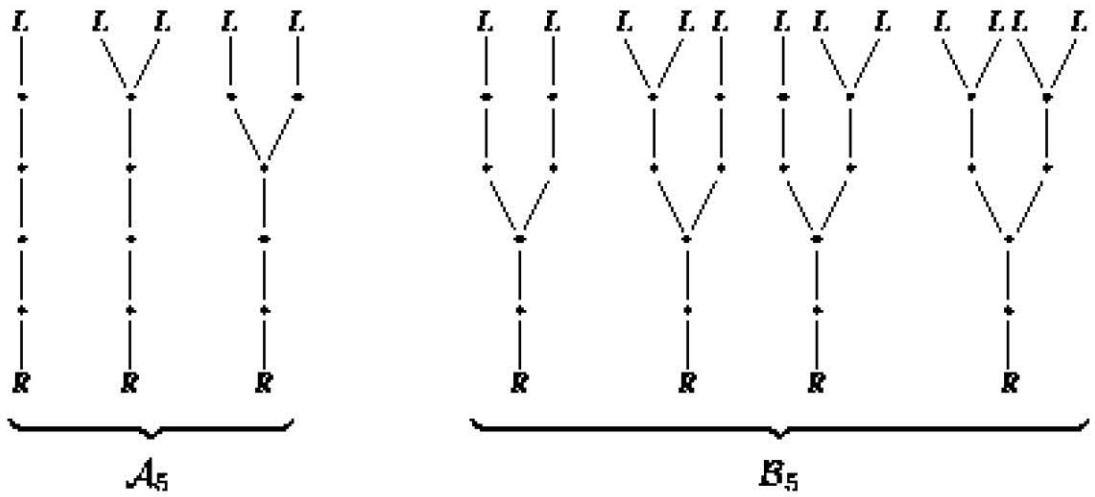


Trees will be drawn here with their roots at the bottom of their pictures. The *level* of a vertex is its distance to the root. The *distance* between two vertices in a tree is the minimum number of edges required to travel from one to the other. A tree with three leaves is displayed. One leaf has level 2 and the two others have level 3. This tree also has two vertices designated v which are neither leaves nor the root. They both have degree 3. One of these has level 1 and the other has level 2.

$\mathcal{H}_n$ will be a set of all rooted trees of a certain type for each integer $n \geq 1$. Every leaf of each tree in $\mathcal{H}_n$ will have level n. Any vertices of degree greater than 1 in trees in $\mathcal{H}_n$ will be one of two types: the diamond ($\blacklozenge$) and the circle ($\bullet$). The diamond will always have degree 3 so the tree must "branch" at a diamond. The distance between two diamonds must always be at least 2, and the level of a diamond must be at least 2. All other vertices of degree greater than 1 will be circles and each circle will have degree 2. There will be no branching at a circle – just a "trunk". Here is a display of some small forests of this species, a rather peculiar sort of binary tree.



The more numerous trees in $\mathcal{H}_5$ can be grouped suggestively.



The forest $\mathcal{H}_5$ divides naturally into a disjoint union of $\mathcal{A}_5$, the trees in $\mathcal{H}_5$ whose level 2 vertex is a circle, and $\mathcal{B}_5$, the trees in $\mathcal{H}_5$ whose level 2 vertex is a diamond. Note that these trees are "oriented": the left and right branches are distinct. More technically, these trees are examples of what are called *simple partially-ordered rooted trees.*

Consider $\mathcal{A}_5$. Delete the root and lowest edge of a tree in this set, and change the lowest circle to a root. The result is an element of $\mathcal{H}_4$. It is not hard to see that this mapping is a bijection.

Now consider $\mathcal{B}_5$. Go to the lowest diamond (which must have level 2) of any tree in $\mathcal{B}_5$. Separate the two branches rising from the diamond, and in each one end the lowest edge by a root. This gives a pair of elements of $\mathcal{H}_3$. This mapping is a bijection of $\mathcal{B}_5$ with $(\mathcal{H}_3)^2$, the set of pairs of trees in $\mathcal{H}_3$.

Thus the number of trees in $\mathcal{H}_5$ is the sum of the number of trees in $\mathcal{H}_5$ and the square of the number of trees in $\mathcal{H}_3$.

Theorem 2 If $n \geq 1$, h_n is the number of trees in $\mathcal{H}_n$.

Proof The correspondence described above extends to $\mathcal{H}_n$ so there is a bijection between $\mathcal{H}_{n+2}$ and $\mathcal{H}_{n+1} \cup (\mathcal{H}_n \times \mathcal{H}_n)$. Then the theorem is true because $\mathcal{H}_1$ and $\mathcal{H}_2$ each contain one tree. ■

Counting the leaves on the trees in a forest

The pictures above invite the question: how many leaves are there in the forest $\mathcal{H}_n$? Suppose that j_n is the number of leaves in the forest $\mathcal{H}_n$.

Then $j_1 = j_2 = 1$ and the sequence $\{j_n\}$ satisfies the recurrence

$$j_{n+2} = j_{n+1} + 2h_n j_n. \qquad (4)$$

This is fairly clear from the bijection described in Theorem 2, since $j_n h_n$ is the total number of leaves which occur on all the left hand trees, or on all the right hand trees, in pairings from $\mathcal{H}_n \times \mathcal{H}_n$.

Equation (4) may also be obtained by the following argument which may be of independent interest. Define a polynomial $P_n(x)$ by

$$P_n(x) = \sum_{T \in \mathcal{H}_n} x^{\ell(T)},$$

where $\ell(T)$ is the number of leaves on the tree T. Then clearly $P_n(1) = h_n$, $P_n'(1) = j_n$, and the sequence of polynomials $\{P_n\}$ satisfies the original recurrence, (1): $P_{n+2} = P_{n+1} + P_n^2$. These equations imply (4).

Note that (4) is the linearization of the recursion (1) for h: if we alter the initial values for (1) by the infinitesimal perturbations $h_1 \to h_1 + dh_1$ and $h_2 \to h_2 + dh_2$ then the resulting perturbation $h_n \to h_n + dh_n$ satisfies

$$dh_{n+2} = dh_{n+1} + 2h_n dh_n$$

up to higher order terms.

The recursion (4) can be compared to the simpler recursion,

$$J_{n+2} = 2h_n J_n, \qquad (5)$$

which has solution $J_{2m+2} = J_2 2^m \prod_{k=1}^{m} h_{2k}$ and $J_{2m+3} = J_1 2^m \prod_{k=1}^{m} h_{2k+1}$. Numerical experiments indicate that if (4) and (5) are given the same initial values, i.e., $J_1 = j_1$ and $J_2 = j_2$, then $\frac{j_{2m}}{J_{2m}}$ and $\frac{j_{2m+1}}{J_{2m+1}}$ converge rapidly to (different) constants. Analytically (from the known asymptotics of h_n) and numerically it appears that $\frac{2^m h_{2m}}{J_{2m}}$ and $\frac{2^m h_{2m+1}}{J_{2m+1}}$ also converge to constants. So apparently $j_{2m+\theta} \approx C_\theta 2^m h_{2m+\theta}$ for $\theta = 0, 1$. Therefore the mean number of leaves per tree in $\mathcal{H}_n$ is asymptotically a constant (which

constants. So apparently $y_{2m+\theta} \approx C_\theta 2^m n_{2m+\theta}$ for $\theta = 0, 1$. Therefore the mean number of leaves per tree in $\mathcal{H}_n$ is asymptotically a constant (which depends on the parity of n) multiple of $(\sqrt{2})^n$.

An approach to more general recurrences with some experimental results

We suggest here one way to analyze sequences defined by polynomial recurrence relations. Begin with a recurrence which can be solved exactly:

> Suppose that $h_{n+2} = h_{n+1}h_n$ with initial condition $(h_0, h_1) = (1, 2)$. An explicit formula is given by $h_n = 2^{(n^{\text{th}} \text{ Fibonacci number})}$. Standard asymptotics for the Fibonacci numbers then imply $h_n \approx K^{\nu^n}$ for n large with $K = 2^{1/\sqrt{5}} \approx 1.363$ and $\nu = \frac{1+\sqrt{5}}{2} \approx 1.618$.

We briefly explain how to find a similar expression for any recurrence determined by one monomial. We assume that

$$h_{n+k} = c\, h_n^{\tau_0} h_{n+1}^{\tau_1} \cdots h_{n+k-1}^{\tau_k}, \tag{6}$$

where c is a positive constant and each of the exponents τ_j is a nonnegative integer. We further assume that $\tau_0 > 0$ and that a k-tuple of nonnegative initial values $(h_0, \ldots, h_{k-1})$ is given.

Then the sequence $\{\log h_n\}$ satisfies a linear recurrence with characteristic polynomial $p(x) = x^k - \tau_{k-1}x^{k-1} - \ldots - \tau_1 x - \tau_0$, which can be solved exactly using classical techniques. If $p(1) \neq 0$ ($p(1)$ vanishes only in the uninteresting case $p(x) = x - 1$) then $h_n = C \prod_{i=0}^{k-1} A_i^{\lambda_i^n}$ where $\lambda_0, \ldots, \lambda_{k-1}$ are the roots of p, $C = c^{1/p(1)}$, and $A_0, \ldots, A_{k-1}$ are constants determined by the initial conditions.

Suppose j is the maximum integer so that $p(x) = q(x^j)$ for some polynomial q of degree $m = k/j$. If q has roots $\{\mu_0, \ldots, \mu_{m-1}\}$ then the roots $\{\lambda_0, \ldots, \lambda_{k-1}\}$ of p can be numbered so that $\lambda_{jr+l}^j = \mu_r$ for $l = 0, 1, \ldots, j-1$ and $r = 0, \ldots, m-1$. When $j > 1$, (6) becomes

$$h_{jn+l} = C \prod_{r=0}^{m-1} B_{r,l}^{\mu_r^n}, \; l = 0, 1, \ldots, j-1, \tag{7}$$

$r=0$

where $B_{r,l} = \prod_{s=0}^{j-1} A_{jr+s}^{\lambda_{jr+s}^l}$.

The polynomial $p(x)$ has one positive root ν. We let $\nu = \lambda_0 = \mu_0^{1/j}$. The roots $\lambda_0, \ldots, \lambda_{j-1}$ then all have magnitude $\nu(p)$ and make the dominant contribution to the growth of h_n since $\nu > |\lambda_i|$ for $i \geq j$.

This suggests one way to analyze polynomial recurrences with positive coefficients. We suppose that the recurrence is

$$h_{n+k} = \sum_{\alpha} c_\alpha \, h_n^{r_{\alpha,0}} \, h_{n+1}^{r_{\alpha,1}} \cdots h_{n+k-1}^{r_{\alpha,k-1}}, \tag{8}$$

where each term in the finite sum has positive coefficient c_α and all exponents $r_{\alpha,i}$ are nonnegative integers as in (6). Each term has an associated characteristic polynomial, $p_\alpha(x) = x^k - \sum_{i=0}^{k-1} r_{\alpha,i} x^i$, which in turn has a unique positive root ν_α.

If one term indexed by β is *dominant* in the sense that $\nu_\beta > \nu_\alpha$ for $\alpha \neq \beta$, then simulations and some heuristic reasoning suggest that if the initial conditions are chosen large enough so that $h_n \to \infty$, then h_n behaves asymptotically like the exact solution (7) of the recurrence with only this dominant term:

$$\lim_{n \to \infty} h_n \Big/ \left(C \prod_{i=0}^{k-1} A_i^{\lambda_{\beta,i}^n} \right) = 1, \tag{9}$$

where again $C = c^{1/p(1)}$ but now $A_0, \ldots, A_{k-1}$ depend on the remaining terms in the recurrence as well as on the initial condition.

The recurrence (1) analyzed previously has dominant term, h_n^2, with

The recurrence (1) analyzed previously has dominant term, h_n^2, with $C = 1$, $k = 2$, $j = 2$, and $\nu = \sqrt{2}$. In this case, $C\prod_{i=0}^{k-1} A_i^{\lambda_{n,i}^n}$ is $A_0^{(\sqrt{2})^n} A_1^{(-\sqrt{2})^n}$. When n is even this is $(A_0A_1)^{(\sqrt{2})^n}$ and when n is odd it is $(A_0/A_1)^{(\sqrt{2})^n}$. Theorem 1 therefore verifies (9) with $A_0A_1 \approx 1.436$ and $A_0/A_1 \approx 1.451$.

We have no suggestion for the correct asymptotics when (8) has no dominant term, nor have we proved (9) in general. Here is a report of some numerical experiments which also support (9):

Recurrence and initial condition	k, j, ν for the dominant term	Observed asymptotics
$h_{n+2} = h_{n+1} + (h_n)^3$, $(0,1)$	$2,\ 2,\ 3^{1/2}$	$h_n \approx (K_l)^{3^{n/2}}$, $n \equiv l\ (2)$ for $\begin{cases} K_0 \approx 1.144 \\ K_1 \approx 1.166 \end{cases}$
$h_{n+3} = h_{n+2} + (h_n)^2$, $(0,0,1)$	$3,\ 3,\ 2^{1/3}$	$h_n \approx (K_l)^{2^{n/3}}$, $n \equiv l\ (3)$ for $\begin{cases} K_0 \approx 1.454 \\ K_1 \approx 1.438 \\ K_2 \approx 1.442 \end{cases}$
$h_{n+3} = (h_{n+2})^2 + h_n$, $(0,0,1)$	$1,\ 1,\ 2$	$h_n \approx (1.0257)^{2^n}$
$h_{n+2} = (h_{n+1})^2 + (h_n)^2$, $(0,1)$	$1,\ 1,\ 2$	$h_n \approx (1.111)^{2^n}$

Algebraic identities

Suppose $S = \{s_0, s_1, \ldots\}$ is any sequence of integers, and n is a positive integer. Let $S_n \subset \mathbb{Z}^n$ be the set of all consecutive n-tuples of elements of S: $(x_1, \ldots, x_n) \in S_n$ exactly when $x_j = s_{k+j}$ for some $k \geq 0$ and all j between 1 and n. Define $I_{S,n}$ to be the ideal of polynomials with integer coefficients in n variables (elements of $\mathbb{Z}[X_1, \ldots, X_n]$) which vanish on S_n. If S is defined as the solution of a recurrence which is polynomial with integer coefficients as discussed above then the recurrence itself produces elements of $I_{S,n}$ for n sufficiently large. When do these elements generate $I_{S,n}$? A specific example may be useful. If F is the sequence of Fibonacci numbers, then $I_{F,3}$ contains $X_1 + X_2 - X_3$, determined by the generating recurrence. $I_{F,3}$ is not principal since it also contains $(X_1X_3 - (X_2)^2)^2 - 1$ (from the classical Cassini identity).

(from the classical Cassini identity).

Suppose $H = \{h_0, h_1, \ldots\}$ is the sequence studied in this paper, so $h_{n+2} = h_{n+1} + (h_n)^2$ with $(h_0, h_1) = (0, 1)$. Is $I_{H,3}$ a principal ideal generated by $(X_1)^2 + X_2 - X_3$? Is $I_{H,4}$ generated by $(X_1)^2 + X_2 - X_3$ and $(X_2)^2 + X_3 - X_4$? In other words, does the sequence H satisfy any finite width polynomial identity which is *not* implied by the generating relation? This seems unlikely but we do not know a proof.

There are More Than $2^{n/17}$ n-Letter Ternary Square-Free Words

Shalosh B. Ekhad and Doron Zeilberger
Department of Mathematics,
Temple University, Philadelphia, PA 19122, USA.
Email: zeilberg@math.rutgers.edu

Abstract: We prove that the "connective constant" for ternary square-free words is at least $2^{1/17}$ = 1.0416... improving on Brinkhuis and Brandenburg's lower bounds of $2^{1/24}$=1.0293... and $2^{1/21}$=1.033... respectively. This is the first improvement since 1983.

A word is *square-free* if it never stutters, i.e. if it cannot be written as axxb for words a,b and non-empty word x. For example, "example" is square-free, but "exampample" is not. See Steven Finch's Mathematical Constants site[4] for a thorough discussion and many references. Let a(n) be the number of ternary square-free n-letter words (A006156, M2550 in the Sloane-Plouffe[5] listing, 1,3,6,12,18,30,42, ...). Brinkhuis[3] and Brandenburg[2] (see also [1]) showed that a(n) is greater than $2^{n/24}$, and $2^{n/21}$ respectively. Here we show, by extending the method of [3], that a(n) is greater than $2^{n/17}$, and hence that mu:=the limit of $a(n)^{1/n}$ as n goes to infinity, is larger than $2^{1/17}$=1.0416... .

Definition: A triple-pair [[U0,V0],[U1,V1],[U2,V2]] where U0, V0, U1, V1, U2, V2 are words in the alphabet {0,1,2} of the same length k, will be called a **k-Brinkhuis triple-pair** if the following conditions are satisfied.

- The 24 words of length 2k, [U or V]0 [U or V]1 , [U or V]0 [U or V]2, [U or V]1 [U or V]2, [U or V]1 [U or V]0, [U or V]2 [U or V]0, [U or V]2 [U or V]1, (i.e. U0U1, U0V1, ..., V2V1), are all square-free.
- For every length r, between k/2 and k , the 12 words consisting of the heads and tails of U0,U1, U2,V0,V1,V2 of length r are all distinct.

It is easy to see (directly, or by adapting the argument in [3]), that if [[U0,V0],[U1,V1],[U2,V2]] is a k-Brinkhuis triple-pair, then for every square-free word $x=x_1...x_n$ of length n in the alphabet {0,1,2}, the 2^n words of length nk, [U or V]x_1[U or V]x_2...[U or V]x_n are also all square-free. Thus the mere existence

of a k-Brinkhuis triple-pair implies that a(nk) is greater than 2^n *a(n), which implies that mu is greater than $2^{1/(k-1)}$.

Theorem: The following is an 18-Brinkhuis triple-pair

[[210201202120102012, 210201021202102012],
[021012010201210120, 021012102010210120],
[102120121012021201, 102120210121021201]].

Proof: Purely routine!

Remark: The above 18-Brinkhuis triple-pair was found by the first author by running procedure FindPair (); in the Maple package JAN, written by the second author.

Another Remark: Brinkhuis[3] constructed a 25-Brinkhuis triple-pair in which U0 and V0 were palindromes, and U1, U2, were obtained from U0 by adding, component-wise, 1 and 2 mod 3, respectively, and similarly for V1, V2. Our improved example resulted from relaxing the superfluous condition of palindromity, but we still have the second property. It is very likely that by relaxing the second property, it would be possible to find even shorter Brinkhuis triple-pairs, and hence get yet better lower bounds for mu. Alas, in this case the haystack gets much larger!

Errata and Addenda: ``There Are More Than 2** (n/17) n-Letter Ternary Square-Free Words'' By S. B. Ekhad and D. Zeilberger

Appeared in Journal of Integer Sequences, 98.1.9.

Added March 30, 2001: Jon McCammond wrote a more efficient program (using GAP) that showed that even with the much larger haystack, in which the components Brinkhuis pairs are not related, one still gets the same kind of needles, i.e. 2^(1/17) is best possible (with this method).

Added June 12, 2001: Erratum: Uwe Grimm pointed out that the definition of Brinkhuis triple-pair, as stated, is insufficient to guarantee square-freenes-preservation of the homomorphisms, by presenting a counterexample (see Uwe Grimm's message). However, this is easily fixed. The first condition for being a Brinkhuis triple-pair is equivalent to demanding that

for every square-free word of length 2: [a,b] (there are six of them) the four words
[U or V]_a [U or V]_b
are all square-free.

This condition needs to be replaced by the following condition.

For every square-free word of length 3: [a,b,c] (there are twelve of them) the eight words
[U or V]_a [U or V]_b [U or V]_c ,
are square-free.

It is readily checked (by hand, or use procedure Images1 in JAN), that the proposed Brinkhuis triple-pair is indeed one, even in this new, stronger sense, hence the conclusion of the paper is upheld.

I than Uwe Grimm for his careful reading, and for spotting this inaccuracy.

On Cayley's Enumeration of Alkanes (or 4-Valent Trees)

E. M. Rains and N. J. A. Sloane
Information Sciences Research
AT&T Shannon Lab
Florham Park, NJ 07932-0971

Email addresses: rains@research.att.com, njas@research.att.com

Abstract: Cayley's 1875 enumerations of centered and bicentered alkanes (unlabeled trees of valency at most 4) are corrected and extended – possibly for the first time in 124 years.

1. Introduction

In 1875 Cayley attempted to enumerate alkanes C_nH_{2n+2}, or equivalently n-node unlabeled trees in which each node has degree at most 4, and published a short note [Cay75] containing the table:

n	1	2	3	4	5	6	7	8	9	10	11	12	13	
centered	1	0	1	1	2	2	6	9	20	37	86	183	419	(1)
bicentered	0	1	0	1	1	3	3	9	15	38	73	174	380	(2)
total	1	1	1	2	3	5	9	18	35	75	159	357	799	(3)

(The terms "centered" and "bicentered" are defined below.) This table was reproduced by Busacker and Saaty in 1965 [BuS65], and the three sequences were included in [HIS].

In fact the last two columns are in error, as had already been pointed out by Herrmann in 1880 [Her80]. Herrmann uses a different method from Cayley, and gives the correct values 355 (for n=12) and 802 (for n=13) for sequence (3). However, neither in [Her80] nor in his two later notes [Her97], [Her98] does he mention sequences (1) and (2).

The alkane sequence (3) is also discussed in the works by Schiff [Sch75], Losanitsch [Los97], [Los97a], Henze and Blaire [HeB31], Perry [Per32], Polya [Polya36], [Polya37], Harary and Norman [HaN60], Lederberg [Led69], Read [Rea76], Robinson, Harary and Balaban [RoHB76], and Bergeron, Labelle and Leroux [BeLL98]. The simplest generating function is due to Harary and Norman (see Section 4 of [Rea76] or p. 289 of [BeLL98]). However, none of these authors use Cayley's method, and as far as we can tell none of them discuss sequences (1) and (2).

In 1988 R. K. Guy wrote to N.J.A.S., pointing out that there were errors in these three sequences, and suggested that Polya counting theory be used to extend (1) and (2). (The correct version of (3), sequence A602, was already present in [HIS].) To do so is the goal of the present note.

We confess to having another, more ignoble reason for wishing to extend sequences (1) and (2). The sequences in the data-base [EIS] are numbered (A1, A2, A3, ...), and several people have suggested that the "diagonal" sequence, whose *n*th term is the *n*th term of A*n*, should be added to [EIS]. The fact that (1) is sequence A22 provided additional motivation for extending it to at least the 22nd term! (The "diagonal" sequence is now in the data-base, sequence A31135, as is the even less well-defined A37181 whose *n*th term is 1 + *n*th term of A*n*.)

The hard part was determining exactly what Cayley was attempting to count, since [Cay75] is somewhat unclear, and contains many typographical errors. Once the problem was identified, it turned out to be quite easy to calculate these sequences - so in fact it is very likely that this has been done in the 124 years since [Cay75] appeared. But we have been unable to find any record of it in the literature.

2. Generating functions

A tree of diameter 2*m* has a unique node called the *center*, at the midpoint of any path of length 2*m*. A tree of diameter 2*m*+1 has a unique pair of nodes called *bicenters*, at the middle of any path of length 2*m* +1. These terms were introduced by Jordan around 1869 ([Har69], p. 35).

Cayley's approach [Cay75] to counting alkanes uses the notions of center and bicenter to reduce the problem to simpler questions about rooted trees. This turns out to be an awkward way to attack the problem (since the notion of diameter is irrelevant), and may explain why no one else has used this approach.

It is simpler to make use of the notion of "centroid" and "bicentroid", also due to Jordan (see Harary [Har69], p. 36, for the definition). In 1881 Cayley [Cay81] found recurrences for the numbers of *n*-node trees with a centroid (sequence A676) and with a bicentroid (A677), which gave him a simpler way to enumerate unrooted trees (A55). However, as far as we know Cayley did not use the centroid/bicentroid method to enumerate alkanes (A602). This was apparently first done by Polya [Polya36], [Polya37] in

1936.

However, our concern here *is* with centered and bi-centered trees.

We will say that a tree is *k-valent* if the degree of every node is at most *k*. Alkanes are precisely the 4-valent trees.

We wll also consider rooted trees, and define a *b-ary* rooted tree to be either the empty tree or a rooted tree in which the out-degree of every node (the valency excluding the edge connecting it to the root) is at most *b*. This generalizes the notion of a *binary* rooted tree, the case *b*=2, which is either the empty tree or a rooted tree in which every node has 0, 1 or 2 sons. (The literature contains several other definitions of binary and *b*-ary trees. These terms sometimes refer specifically to planar trees. Our trees are not planar, and in particular there is no notion of right or left.)

We will find generating functions for centered and bicentered *k*-valent trees.

Fix *k*, and let $T_{h,n}$ be the number of (*k*-1)-ary rooted trees with *n* nodes and height at most *h*. (The height of a node in a rooted tree is the number of edges joining the node to the root.) By convention the empty tree has height -1. Let $T_h(z) = \text{SUM}_{n>=0}\ T_{h,n}\ z^n$. Then $T_{-1}(z) = 1$, $T_0(z) = 1+z$, and for $h>1$,

$$T_{h+1}(z) = 1+ z\ \mathbf{S}_{k-1}(T_h(z)), \qquad (4)$$

where $\mathbf{S}_m(f(z))$ denotes the result of substituting $f(z)$ into the cycle index for the symmetric group of order *m*!. For example,

$$\mathbf{S}_3(f(z)) = (f(z)^3 + 3 f(z) f(z^2) + 2 f(z^3)) / 3!.$$

Equation (4) holds because if we remove the root and adjacent edges from a rooted tree of height *h*+1 we are left with an unordered (*k*-1)-tuple of trees of height *h*.

Let $C_{2_{h,n}}$ be the number of centered *k*-valent trees with *n* nodes and diameter 2*h*, and let $C_{2_h}(z) = \text{SUM}_{n>=0}\ C_{2_{h,n}}\ z^n$. By deleting the center node and adjacent edges, we see that any such tree corresponds to an unordered *k*-tuple of (*k*-1)-ary rooted trees of height at most *h*-1, at least two of which have height exactly *h*-1. Therefore

$$C_{2_h} = (1+ z\ \mathbf{S}_k(T_{h-1}(z))) - (1+ z\ \mathbf{S}_k(T_{h-2}(z))) - (T_{h-1}(z)-T_{h-2}(z))(T_{h-1}(z) - 1). \qquad (5)$$

The three expressions in (5) account for the *k*-tuples of rooted trees of height at most *h*-1, *k*-tuples of

rooted trees of height at most h-2, and rooted trees with exactly one subtree at the root with height h-1, respectively.

Finally, let C_n denote the number of centered k-valent trees with n nodes, and $C(z) = \text{SUM}_{n>=0}\, C_n z^n$. Then

$$C(z) = \text{SUM}_{h>=0}\, C_{2h}(z) .$$

For $k = 4$ we obtain

$$C(z) = z + z^3 + z^4 + 2\,z^5 + 2\,z^6 + 6\,z^7 + 9\,z^8 + 20\,z^9 + 37\,z^{10} + 86\,z^{11} + 181\,z^{12} + 422\,z^{13} + \ldots ,$$

which is the corrected version of Cayley's sequence (1), A22. (See the table below.)

Bicentered trees are easier to handle. Let $B_{2h+1,n}$ be the number of bicentered k-valent trees with n nodes and diameter $2h+1$, let $B_{2h+1}(z) = \text{SUM}_{n>=0}\, B_{2h+1,n}\, z^n$, let B_n be the total number of bicentered k-valent trees with n nodes, and let $B(z) = \text{SUM}_{n>=0}\, B_n z^n$. Since a bicentered tree corresponds to an unordered pair of (k-1)-ary rooted trees of height exactly h, we have

$$B_{2h+1}(z) = \mathbf{S}_2\,(T_h(z) - T_{h-1}(z)) ,$$

and then

$$B(z) = \text{SUM}_{h>=0}\, B_{2h+1}(z) .$$

For $k = 4$ we obtain

$$B(z) = z^2 + z^4 + z^5 + 3\,z^6 + 3\,z^7 + 9\,z^8 + 15\,z^9 + 38\,z^{10} + 73\,z^{11} + 174\,z^{12} + 380\,z^{13} + \ldots ,$$

Cayley's sequence (2), A200 (which as it turns out was correct).

The generating function for alkenes (A602) is then

$$C(z) + B(z) = z + z^2 + z^3 + 2\,z^4 + 3\,z^5 + 5\,z^6 + 9\,z^7 + 18\,z^8 + 35\,z^9 + 75\,z^{10} + 159\,z^{11} + 355\,z^{12} + 802\,z^{13} + \ldots ,$$

in agreement with Henze and Blair [HeB31] (except that the value they give for n = 19, 147284, is

incorrect: it should be 148284). Further terms are shown in the following table:

Table:Numbers of centered, bicentered and unrestricted 4-valent trees with *n* nodes

n	centered	bicentered	total
	(A22)	(A200)	(A602)
1	1	0	1
2	0	1	1
3	1	0	1
4	1	1	2
5	2	1	3
6	2	3	5
7	6	3	9
8	9	9	18
9	20	15	35
10	37	38	75
11	86	73	159
12	181	174	355
13	422	380	802
14	943	915	1858
15	2223	2124	4347
16	5225	5134	10359
17	12613	12281	24894
18	30513	30010	60523
19	74883	73401	148284
20	184484	181835	366319
21	458561	452165	910726
22	1145406	1133252	2278658
...	...	...	...

If we set $k = 3$ in the above formulae (corresponding to centered, bicentered and unrestricted 3-valent

trees), we obtain sequences A675, A673 and A672, for which the initial terms were (correctly) published by Cayley in another 1875 paper [Cay75a], and further terms were computed by R. W. Robinson in 1975 [Rob75].

For $k = 5$ and 6 the resulting sequences (A36648, A36649, A36650, A36651, A36652, A36653) appear to be new.

Abstract: The HR (or Hardy-Ramanujan) program invents and analyses definitions in areas of pure mathematics, including finite algebras, graph theory and number theory. While working in number theory, HR recently invented a new integer sequence, the refactorable numbers, which are defined and developed here. A discussion of how HR works, along with details of well known sequences reinvented by HR and other new sequences invented by HR is also given.

Contents

1. Introduction

The following sequence of integers has recently been accepted into the OnLine Encyclopedia of Integer Sequences, [9]:

[A033950]: 1, 2, 8, 9, 12, 18, 24, 36, 40, 56, 60, 72, 80, 84, 88, 96, 104, 108, 128, 132, 136, 152, 156, ...

The sequence is interesting for two reasons:

- It has a simple definition: those integers *n* for which the number of divisors of *n* divides *n*.
- It was invented by a computer program.

This note gives some results about the refactorables, followed by a discussion of the HR program which invented them and a look at some of the other sequences HR has invented or reinvented.

2. Refactorable Numbers

Notation. Throughout, the number of divisors of an integer, *n*, is written *tau*(*n*), the sum of the divisors of *n* is written *sigma*(*n*) and the number of integers less than and coprime to *n* is written *phi*(*n*).

Definition. An integer, *n*, is a **refactorable** number if and only if *tau*(*n*) divides *n*.

Lemma 1. (Theorem 273 from [4]) If the prime factorization of *n* is

$$n = p_1^{m_1} \ldots p_k^{m_k}$$

then *n* has $(m_1 + 1) \ldots (m_k + 1)$ divisors.

Lemma 2. An odd integer *k* is refactorable if and only if 2*k* is refactorable.

Proof. Suppose $k = p_1^{m_1} \ldots p_k^{m_k}$ By Lemma 1, if *k* is refactorable, $(m_1 + 1) \ldots (m_k + 1)$ divides *k*. Therefore the number of divisors of *2k*, namely $2(m_1 + 1)\ldots(m_k + 1)$, divides 2*k*, and so 2*k* is refactorable. The converse follows by reversing the steps of the argument. QED.

Theorem 1. There are infinitely many odd refactorable numbers, and infinitely many even refactorable numbers.

Proof. From Lemma 1, if p is a prime, $q = p^p - 1$ has p divisors, and so q is refactorable. The result now follows from Lemma 2. QED.

The set of integers of the form $p^p - 1$ forms a subsequence of the refactorable numbers:

[A036878]: 2, 9, 625, 117649, 25937424601, 23298085122481, 48661191875666868481, ...

A more interesting way to prove Theorem 1 is to take the integers in numerical order, find their prime factorizations and apply the map:

$$p_1^{m_1} \cdots p_k^{m_k} \longrightarrow p_1^{p_1^{m_1}-1} \cdots p_k^{p_k^{m_k}-1}$$

For example:

$$3 = 3^1 \quad \text{becomes} \quad 3^{3^1-1} = 9$$

and

$$6 = 2^1 3^1 \quad \text{becomes} \quad 2^{2^1-1} 3^{3^1-1} = 18$$

It is easy to see that the integers produced from this map must all be refactorable numbers, as they have $p_1^{m_1} \ldots p_k^{m_k}$ divisors, and for any prime p and any integer m we have $m <= p^m-1$, so the number of divisors divides the integer itself. The result of the transformation on a even number is another even number, and the result on an odd number is another odd number. It follows that there are infinitely many even and odd refactorable numbers.

This mapping of the integers onto the refactorables produces another interesting sequence:

[A036879]: 1, 2, 9, 8, 625, 18, 117649, 128, 6561, 1250, 25937424601, 56, 23298085122481, 235298, ...

This sequence does not of course include all refactorable numbers: it is easy to show that 12, for instance, does not belong to this sequence.

2.1 Membership Theorems

Since primes have two divisors, 2 is the only prime refactorable number.

Theorem 2. All odd refactorable numbers are squares.

Proof. Suppose n is as in Lemma 1, and is odd and refactorable. Since each $m_i + 1$ must divide n, each m_i is even, so n is a square. QED.

Theorem 2 makes it easy to search for odd refactorable numbers, which form this subsequence:

[A036896]: 1, 9, 225, 441, 625, 1089, 1521, 2025, 2601, 3249, 4761, 5625, 6561, 7569, 8649, ...

The odd numbers which square to give these are:

[A036897]: 1, 3, 15, 21, 25, 33, 39, 45, 51, 57, 69, 75, 81, 87, 93, ...

(It is easy to see that 3 is the only prime in this series.)

Theorem 3. No perfect number is refactorable.

Proof.
(a) Even perfect numbers. Using Theorem 277 from [4], we know that if k is an even perfect number, it has the form $2^{n-1}(2^n-1)$, where 2^n-1 is a prime, p, and using Theorem 18 from [4], we know that if 2^n-1 is prime, then so is n. Using Lemma 1, we know that $k = 2^{n-1}p$ must have $((n-1)+1)(1+1) = 2n$ divisors. If $2n$ divides k then either $n = 2$ or $n = p$ (as n is a prime). If $n = 2$ then the perfect number is 6, which is not refactorable. If $n = p$ then $n = 2^n-1$, which is impossible for a prime n.
(b) Odd perfect numbers. No odd perfect numbers are known. If one were to exist, say q, with divisors $d_1 < ... < d_k = q$, then each d_i must be odd, and by definition, $d_1 + ... + d_{k-1} = q$. The sum of an even number of odd integers is even, so, as q is odd, we know that $k-1$ must be odd, so q has an even number of divisors. Therefore q cannot be refactorable as it is odd and cannot be divisible by an even number. QED.

2.2 Pairs and Triples of Refactorable Numbers

Because odd refactorables are square numbers, we cannot have four or more consecutive refactorables, since positive squares always differ by more than 2. We cannot yet rule out triples of refactorable numbers, but we can show that it is very unlikely that they exist:

Theorem 4. If (a-1, a, a+1) is a triple of refactorable numbers, then a must be of the form:

$$\left(\sum_{i=0}^{n} 2^i \binom{2n+1}{2i}\right)^2$$

for some integer n.

Proof. As odd refactorable numbers are square, and as no two square numbers differ by 2, a must be odd and a square, say b^2. An instance of the Fermat-Euler theorem (Theorem 72 from [4]) states that $b^2 = 1 \pmod 4$, so $b^2 + 1 = 2 \pmod 4$. Therefore $a + 1$ is not divisible by 4 and so must have prime factorization $a + 1 = 2\ {p_1}^{m_1} \ldots {p_k}^{m_k}$, where the p_i's are distinct odd primes. This means that $tau(a+1) = 2(m_1+1)\ldots(m_k+1)$ and that each m_i+1 must be odd as $a+1$ is refactorable. So each m_i must be even and therefore $a+1$ is twice an odd square number. Therefore we can write $a+1 = 2c^2$, so $b^2 + 1 = 2c^2$. This means that (b,c) must be a solution of the Diophantine equation $x^2 - 2y^2 = -1$. Theorem 244 of [4] states that the positive integer solutions to this equation are given by

$$x + y\sqrt{2} = (1 + \sqrt{2})^{2n+1}$$

for integers n. Expanding the coefficient of x on the right-hand side, we get:

$$\sum_{i=0}^{n} 2^i \binom{2n+1}{2i}$$

and so a is as in the statement of the theorem. QED.

These numbers quickly become large. For example, if we take $n = 10$, then $a = 2982076586042449$. By considering $n <= 35$, it is easy to show that there are no triples between 1 and 10^{53}, and it would not be difficult to take this number further.

Conjecture 1. There are no triples of refactorable numbers.

There are, however, pairs of refactorable numbers, although these are fairly rare. The only pairs of refactorable numbers between 1 and 1,000,000 are:

[A036898]: (1 2), (8 9), (1520 1521), (50624 50625), (62000 62001), (103040 103041), (199808 199809), (221840 221841), (269360 269361), (463760 463761), (690560 690561), (848240 848241), (986048 986049)

It is easy to see that if (a, a+1) is a pair of refactorable numbers, and a is even, then a is a multiple of four (from the Fermat-Euler theorem as in the proof of Theorem 4).

If two refactorables are relatively prime, their product is also refactorable. So the products of pairs of consecutive refactorables produces another (possibly finite) sequence of refactorables:

[A036899]: 2, 72, 2311920, 2562840000, 3844062000, 10617344640, 39923436672, ...

Conjecture 2. There are infinitely many pairs of refactorable numbers.

2.3 Distribution

We cannot yet give an accurate measure for the number of refactorables less than a given n, but we can say how many there are with a given number of divisors:

Theorem 5. The number of refactorable numbers with n divisors is:

- 1, if n = 1 or 4.
- k!, if n is the product of k distinct primes (ie. it is square-free:[A005117]).
- infinite, otherwise.

Proof. Clearly, 1 is the only refactorable number with one divisor. If an integer s has four divisors, then it must be of the form p^3 or pq for distinct primes p, q. Taking the first case, if it is to be refactorable, then p = 2 and the refactorable number is 8. There are no refactorables of the form pq because 4 cannot divide the product of two distinct primes.
If n is the product of k distinct primes, $n = p_1 \ldots p_k$, then any integer s with n divisors must be of the form $s = a_1^{p_1 - 1} \ldots a_k^{p_k - 1}$ for distinct primes $a_1, \ldots, a_k$. If it is to be refactorable, then n must divide s, so $\{a_1, \ldots, a_k\} = \{p_1, \ldots, p_k\}$ and there are k! ways to choose the a_i's from the p_i's, hence k! possibilities for s.
Suppose now that n is not square-free, and $n = p_1^{m_1} \ldots p_k^{m_k}$. Firstly, if k = 1, then $n = p^m$ and $m > 1$.
Then for any prime q which is not p, the integer $s = q^{p-1}p^{p^{m-1}-1}$ has n divisors. Further, s is refactorable unless

$$p^{m-1} - 1 < m \iff p = m = 2 \iff n = 4 ,$$

and we have already dealt with the case where $n = 4$. Secondly, if $k > 1$, with say $m_i > 1$, for any prime q not in $\{p_1, ..., p_k\}$, the integer

$$s = q^{p_1-1} p_1^{m_1-1} \dots p_i^{m_i-1-1} \dots p_k^{m_k-1}$$

has n divisors. Now s is also refactorable unless, as above, $p_i = m_i = 2$. If there is an $i > 2$ for which $m_i > 1$, then choosing this i in the construction above works. This leaves only the case where $n = 2^2 p_2 \dots p_k$. In this case, for any prime q not in $\{p_1, ..., p_k\}$, the integer

$$s = q^{2^{p_2-1}} p_2 p_3^{p_3-1} \dots p_k^{p_k-1}$$

has $2p_2\ 2p_3 \dots p_k = n$ divisors, and is refactorable because $p_2 > 2$ implies $p_2 - 1 >= 2$. QED.

Theorem 5 tells us, for instance, that there are precisely two refactorable numbers with 6 divisors, namely 12 and 18, and precisely 6 refactorable numbers with 30 divisors, namely $2^1 3^2 5^4$, $2^1 3^4 5^2$, $2^2 3^1 5^4$, $2^2 3^4 5^1$, $2^4 3^1 5^2$ and $2^4 3^2 5^1$.

Also, for a given non-square-free integer $n = p_1^{m_1} \dots p_k^{m_k}$, if we can write:

$$n = (m_1+t_1) \dots (m_k+t_k)\ a_1 \dots a_j$$

for $j > 0$, and some $t_i > 0$, $a_i > 1$, then for any set of primes, $\{q_1, ..., q_j\}$, none of which are in $\{p_1, ..., p_k\}$, the number:

$$p_1^{m_1+t_1-1} \dots p_k^{m_k+t_k-1} q_1^{a_1-1} \dots q_j^{a_j-1}$$

will have n divisors and be refactorable.

So, for instance, because $36 = 2^2\ 3^2$,

36 = (2+1)(2+1)4 implies $36p^3$ has 36 divisors and is refactorable (for any prime $p > 3$).
36 = (2+1)(2+1)2*2 implies $36pq$ has 36 divisors and is refactorable (for any primes $p, q > 3$).
36 = (2+1)(2+2)3 implies $108p^2$ has 36 divisors and is refactorable (for any prime $p > 3$).
36 = (2+2)(2+1)3 implies $72p^2$ has 36 divisors and is refactorable (for any prime $p > 3$).
36 = (2+1)(2+4)2 implies $972p$ has 36 divisors and is refactorable (for any prime $p > 3$).

36 = (2+4)(2+1)2 implies 288p has 36 divisors and is refactorable (for any prime $p > 3$).

Note that the first such formula comes from the first non-square-free integer greater than 4, namely 8, and we find that 8p is refactorable with 8 divisors, for any prime $p > 2$.

To end the discussion on refactorable numbers, we give a table of the distribution of (i) refactorable numbers, (ii) odd refactorable numbers, (iii) even refactorable numbers, (iv) pairs of refactorable numbers, and we compare these with the distribution of the primes and pairs of primes.

n at most	primes	refactorables	odd refactorables	even refactorables	prime pairs	refactorable pairs
10	4	4	2	2	2	2
10^2	25	16	2	14	8	2
10^3	168	92	5	87	35	2
10^4	1229	665	15	650	205	3
10^5	9592	5257	34	5223	1224	5
10^6	78498	44705	87	44618	8169	13
10^7	664579	394240	237	394003	58980	27
10^8	5761455	?	650	?	440312	75
10^9	50847534	?	1813	?	3424506	187
10^{10}	455052511	?	5152	?	27412679	468
10^{11}	4118054813	?	14889	?	224376048	1219

Table 1: Distribution of refactorable numbers, odd and even refactorables and pairs of refactorables, compared with distribution of primes and prime pairs.

We used UBASIC and GAP to compile this table. Based on this empirical evidence, it appears that the number of refactorables is always at least half the number of primes. Using the prime number theorem, (Theorem 6 of [4]), we can conjecture that the number of refactorables less than x is at least $x/(2\log(x))$.

3. HR - Automatic Concept Formation

The research of the author includes understanding and automating the processes at work when

mathematicians invent new concepts, specifically in finite group theory. This has culminated in the HR system, named after Hardy and Ramanujan, to emphasize both a theory-driven and a data-driven approach to concept formation. HR starts with only the axioms of group theory and ends with definitions and models of concepts it has derived, such Abelian groups, cyclic groups, orders of elements and so on. It does this by:

1. Finding models of groups using the MACE model finder, [5].
2. Storing data from the group tables which details the core concepts in group theory, namely the group operation, the identity element and the inverses of elements.
3. Manipulating this data in one of eight ways to produce a new data-table from one (or two) old ones.
4. Assigning definitions to each new data-table using the information about how they were constructed.

Most of the concepts HR invents are calculations which can be made directly from the group table of a finite group. However, it also makes sequences of groups, for instance, the sequence formed by taking the subgroup generated by the center of the previous group (which produces sequences of length two only). The sequences produced were mostly disappointing. For this reason, we looked towards number theory to see if it was possible to find more interesting sequences using HR's limited set of production rules.

3.1 HR Working in Number Theory

In number theory, HR generated three initial tables for the integers up to 100:

- The set of triples [a, b, c] for which $a = b * c$.
- The set of triples [a, b, c] for which $a = b + c$.
- The set of pairs [a, b] for which b is a digit in the decimal expansion of a.

These were quite arbitrary choices - other choices would lead to different concepts. HR performs concept formation in number theory using the same manipulations as in group theory. It also has three ways to produce sequences of numbers:

1. By taking the sequence of integers with a given property, e.g. the prime numbers.
2. By taking the output of some function on successive integers, e.g. the *tau* function.
3. By finding those integers which, for some function, output an integer larger than any output for a smaller integer, i.e. those integers which set a record, such as the highly composite numbers.

The first time HR was tried in number theory, it invented the refactorable numbers. When we first saw this sequence, we did not know how it was found, but it looked interesting - it had a mix of odd and even numbers, sufficiently many terms between one and a hundred, and no obvious pattern. Therefore we

looked it up in the Online Encyclopedia, and were surprised to find that it was not listed. Only then did we look at the output from HR to see its definition (expecting an unintuitive, complicated explanation), and were then even more surprised that this sequence was missing from the Encyclopedia.

We must point out that HR did only the easy part - it invented the concept - we have done all the rest of the above work. However, HR does make conjectures about refactorables. For example, it made the following conjecture, which we thought was true until a very large counterexample was found:

Conjecture. Given a refactorable number n, let

$$f(n) = |\{(a,b) \text{ in } \mathbf{N} \times \mathbf{N} : ab = n, a =\backslash= b\}| .$$

Then $f(n)$ is **not** a divisor of n if and only if n is a square number.

Proof of [==>] Suppose n is refactorable, that $f(n)$ does not divide n and that n is **not** a square. Then $f(n)$ is equal to the number of divisors of n, and so must divide n, a contradiction.
Disproof of [<==] 36360900, 79388100 and 155600676 are the first three square refactorable number which are divisible by $f(n)$.

Since HR only knew the factorizations of the integers up to 100, the conjecture was not implausible.

Note that there can be no odd refactorable numbers n for which $f(n)$ divides n, because if n is odd and refactorable, it must be a square, and if so, $f(n)$ is one less than the number of divisors of n, so, as n is refactorable, $f(n) + 1$ must divide n, and as n is odd, we cannot have both $f(n)$ and $f(n) + 1$ dividing n, as one of these must be even.

We note that HR has in effect discovered the concept of square numbers, for which both $tau(n)$ and $tau(n)$-1 divide n.

The odd or even square refactorable numbers are:

[A036907]: 1, 9, 36, 225, 441, 625, 1089, 1521, 2025, 2601, 3249, 3600, 4761, 5625, 6561, 7569, 8100, ...

3.2 Recent Developments

3.2.1 Data Mining Using the Encyclopedia

Having down-loaded a copy of the Online Encyclopedia, we have enabled HR to check each sequence it

makes against the database and flag those which it has reinvented. After tidying up the data, we were also able to write an add-on program enabling HR to perform some data mining with the encyclopedia. We are still implementing, experimenting and collating results, but it seems that it is certainly possible to find previously unknown results using data mining. For example, we asked HR to identify any sequences for which the refactorables are a subsequence. It first found [A009230], in which the nth term is lcm(n, $d(n)$), which was not too surprising since for every refactorable number r, lcm(r, $tau(r)$) = r.

Next, HR spotted that the refactorables are a subsequence of [A047466], the integers congruent to 0, 1, 2 or 4 (mod 8). This was an unknown result, which we subsequently proved:

Theorem 6. Refactorable numbers are congruent to 0, 1, 2 or 4 (mod 8).

Proof. Odd refactorables are squares, and therefore congruent to 1 modulo 8. If a refactorable number were congruent to 6 mod 8 then it would be of the form $2(4n+3)$, and by Lemma 2, $4n+3$ would also be refactorable, a contradiction. QED.

This gives us another insight into triples of refactorables:

Corollary. If (a-1, a, a+1) is a triple of refactorable numbers, then $a = b^2$ for some odd number b and $b^2 = 16c + 1$ for some c.

Proof. By Theorem 6, odd refactorables are congruent to 1 (mod 8), hence $a+1 = 8n + 2 = 2(4n + 1)$ for some n. Therefore, as $a + 1$ is refactorable and $4n + 1$ is odd, we see by Lemma 2 that $4n + 1$ is an odd refactorable number. Hence, by Theorem 6 again, $4n + 1 = 8c+1$, so $a + 1 = 2(8c+1)$ and we see that $a = 16c+1$. As a is an odd refactorable, by Theorem 2 we can write $a = b^2$ for some b, and $a = b^2 = 16c+1$. QED.

Another data mining investigation using the encyclopedia, this time to find super-sequences of the perfect numbers ["even" being understood here], showed that perfect numbers are a subsequence of [A009242], with nth term equal to lcm(n, $sigma(n)$). Therefore HR had spotted that, for all (even) perfect numbers p, there is an n such that lcm(n, $sigma(n)$) = p. In the same session, HR also spotted that the even perfect numbers are a subsequence of [A007517], in which the nth term is $phi(n)(sigma(n)-n)$. We have subsequently proved both of these results:

Theorem 7. For any even perfect number p, there is an integer a for which lcm(a, $sigma(a)$) = p, and an integer b for which $phi(b)(sigma(b)-b) = p$.

Proof. From Theorem 277 of [4], we note that $p = 2^{n-1}(2^n-1)$ for some n, where 2^n-1 is a prime. If we take $a = 2^{n-1}$ then

$$sigma(a) = 1 + 2 + ... + 2^{n-1} = 2^n - 1$$

and so lcm(a, $sigma(a)$) = 2^{n-1} (2^n-1) = p, because 2^n-1 is prime.

If we take $b = 2^n$ then $sigma(b) = 2^{n+1}$-1 and only the odd integers less than b will be coprime to it, so

$$phi(b) = b/2 = 2^{n-1}$$

Therefore

$$phi(b)(sigma(b) - b) = 2^{n-1} (2^{n+1} - 1 - 2^n) = 2^{n-1} (2^n - 1) = p.$$

QED.

So HR has highlighted the following appealing parallel between the refactorable numbers and the even perfect numbers:

- Refactorable numbers are of the form lcm(a, $tau(a)$) for some a.
- Perfect numbers are of the form lcm(a, $sigma(a)$) for some a.

We also note that

- Refactorable numbers are those n for which lcm(n, $tau(n)$) = n,
- Perfect numbers are those n for which lcm(n, $sigma(n)$) = $2n$.

3.2.2 A Mathematical Cycle

We have recently been able to complete a cycle of mathematical activities by using the automated theorem prover OTTER [6] to prove some of the conjectures that HR makes in group theory. HR now:

- Invents definitions
- Spots conjectures involving those definitions
- Proves some of the conjectures using OTTER
- Finds counterexamples to some of the conjectures that OTTER fails to prove

Therefore, starting with only the axioms of group theory, HR constructs a theory with (i) examples of groups, (ii) definitions of groups and models of those definitions, (iii) proven conjectures with proofs supplied by OTTER, (iv) open conjectures, where OTTER has failed to find a proof and MACE has failed to find a counterexample.

[2] gives a more detailed description of the HR system, and the following web page is devoted to HR:

http://dream.dai.ed.ac.uk/group/simonco/hr/

4. Other Sequences

4.1 Re-Invented Sequences

After a preliminary examination, we can claim that HR reinvented the following sequences:

1. Sequences resulting from factorization:

    - the square numbers [A000290].
    - the non-squares [A000037].
    - the prime numbers [A000040].
    - the squares of primes [A001248].
    - the primes and squares of primes [A000430].
    - 1 and the odd primes [A006005].
    - 0 if prime, 1 otherwise [A005171].
    - the composite numbers [A002808].
    - the highly composite numbers [A002182].
    - *tau*(*n*), the number of divisors of *n* [A000005].
    - the number of proper divisors [A032741].
    - integers with 4 [A030513], 5 [A030514], etc. divisors.
    - integer square roots or zero [A037213].
    - writing out the divisors [A027750].
    - writing out the proper divisors [A027751].
    - the squarefree integers. [A005117].
    - the powers of 2 [A000079].
    - integers with at most 2 prime factors [A037143].
    - integers not divisible by 3 [A001651].

2. Sequences resulting from addition:

    - the even numbers [A005843].
    - the odd numbers [A005408].
    - writing out the numbers less than n [A005408].
    - 1 together with the even numbers [A004277].
    - 2 together with the odd numbers [A004280].
    - 2,4 and the odd numbers [A004281].

3. Sequences resulting from examination of digits:

    - the repunits [A000042].

- integers with only 2's as digits [A002276].
- integers with a 1 [A011531], 2 [A011532], 3 [A011533], etc. as a digit.
- the repdigits [A010785].
- integers divisible by each non-zero digit [A002796].
- each digit is prime [A046034].
- the numbers with two distinct digits [A031955].
- the number of distinct digits in *n* [A043537].
- number with distinct digits [A010784].
- numbers divisible by every digit [A034838].
- no base 2 digit is a base 10 digit [A037344].
- the natural numbers in base 3 [A007089].

More interesting than the fact that HR reinvented these sequences are the ways in which HR defines them. For example, even numbers are defined as integers n for which there is a natural number m such that $m + m = n$. The natural numbers in base 3 were defined as integers in base 10 which have no digits which can be written as $a + b$ where $a > 0$, $b > 0$ and $a \neq b$. Powers of two were defined as those integers with no odd divisors.

4.2 New Sequences Invented by HR

HR invented many other sequences which were not found in the encyclopedia. Most did not seem of any great interest. However, we deemed the following seven of sufficient interest to be submitted to the encyclopedia.

1. 1, 2, 14, 23, 29, 34, 46, 63, 68, 74, 76, 78, 88, 94, ... [A036433],
   the number of divisors is a digit in the decimal expansion of n. This sequence contains all primes with a 2 in them, and those primes starting with a 2, [A045708].

2. 1, 4, 9, 11, 14, 19, 41, 44, 49, 91, 94, 99, ... [A036435],
   those integers where all the digits are nonzero squares.

3. 0, 1, 0, 1, 1, 0, 2, 0, 1, 1, 0, 2, 1, 1, 1, 0, 0, ... [A036431],
   $f(n) = |\{a < n : a + tau(a) = n\}|$.

4. 1, 3, 6, 8, 11, 16, 17, 20, 22, 23, 27, 29, ... [A036434],
   integers which cannot be written as $a + tau(a)$ for some a (i.e. those n for which $f(n) = 0$).

5. 1, 2, 7, 38, 122, 2766, 64686, ... [A036432],
   integers that set a record for $f(n)$.

6. 1, 4, 6, 10, 12, 14, 22, 24, 26, 27, ... [A036438],
   integers which can be written as $m * tau(m)$ for some m (which of course include twice the primes, [A001747]).

7. 1, 6, 8, 10, 14, 15, 22, 26, 27, ... [A036436],
   integers for which $tau(n)$ is a square. This sequence contains the multiplicatively perfect numbers [A007422], n such that the product of the divisors of n equals n^2.

HR has also found some interesting finite sequences of integers. For example, HR invented those integers which have more distinct digits than any smaller number

1, 10, 102, 1023, 10234, 102345, 1023456, 10234567, 102345678, 1023456789 [A038378].

5. Conclusions

We have shown that refactorable numbers are of some interest, and hope that someone will take up the challenge of proving the conjectures from this paper (before we do).

Also, we have shown that HR is capable of producing interesting concepts. Automated concept formation programs have some advantages over humans, in that they have no pride (are not ashamed to look at concepts with simple descriptions) and are very thorough. The use of computers with integer sequences has also been explored in [7], where the Seek-Whence program was used to identify definitions of integer sequences. Indeed, the Superseeker server for the Online Encyclopedia of Integer Sequences does a certain amount of concept formation in attempting to find a match between a given sequence and one in the database. A similar program to HR is Graffiti, [3], which makes conjectures in graph theory. Another program, [1], automatically invents theorems in plane geometry.

Machine discovery in mathematics and in science in general is a productive and interesting area which is gaining recognition and attention. HR and refactorable numbers were themselves recently mentioned in the popular press, [8], which reflects the interest that machine discovery is attracting. As more work is done in this area, we hope to make discovery programs as much a part of the mathematician's tool box as computer algebra packages.

6. Acknowledgements

This work is supported by EPSRC research grant GR/L 11724. I would like to thank Prof. Alan Bundy and Dr. Toby Walsh (who gave refactorables their name) for their valuable contributions to this work.

8. Addenda, April 19, 1999

In this paper we tried to make two points: (i) that the HR program we have implemented can invent new and interesting concepts in number theory and (ii) that one concept output by HR, namely the refactorable numbers, had many interesting properties. Because refactorables and associated sequences were missing from the Encyclopedia of Integer Sequences, [9], and after a preliminary search of the relevant literature, we concluded that the refactorable numbers were a genuinely new invention.

However, on 23rd March 1999, we received notification from Robert Kennedy and Curtis Cooper, of Central Missouri State University, that they had read the above paper and that the concept of

refactorables had been defined already as `tau numbers' in a 1990 paper, [10], which proved that the natural density of the tau numbers is zero.

This news detracts from our original paper in only one way, namely that the title is inaccurate, refactorables were a machine re-invention. Indeed, the news that they have been developed so recently adds both to the point that HR can invent and re-invent concepts of interest and, of course, to the point that refactorables are interesting.

To add to the argument that HR produces interesting, novel concepts in number theory, we present the following very simple function defined by HR recently:

$$f(n) = |\{(a,b) : a * b = n \text{ and } a \mid b\}|.$$

This has been added to the encyclopedia:

[A046951]: 1, 1, 1, 2, 1, 1, 1, 2, 2, 1, 1, 2, 1, 1, 1, 3, 1, 2, 1, 2, 1, 1, 1, 2, 2, 1, 2, 2, 1, 1, 1, 3, 1, 1, 1, 4, 1, ...

This was interesting because of its similarity to the tau function, [A000005]: (*tau(n)* = number of divisors of *n*). HR went on to define the integer sequence of numbers which set a record for *f* (ie. those integers, *a*, for which for all *b*, $0 < b < a$, $f(a) > f(b)$):

[A046952]: 1, 4, 16, 36, 144, 576, 1296, 2304, 3600, 14400, 32400, 57600, 129600, 518400, ...

It was easy to spot that these are all square numbers, but a little investigating revealed the following result:

Theorem 1. The nth integer setting the record for *f* as above is the square of the nth highly composite number [A002182] (the highly composite numbers have more divisors than any smaller integer).

To prove this, we need the following lemma:

Lemma 1. *f(n) = tau(square root of the largest square dividing n)*. Note that the square root of the largest square dividing *n*, which we write as *s(n)*, is integer sequence [A000188].

Proof of Lemma 1.
Writing $n=p_1^{k_1}...p_m^{k_m}$, the largest square dividing *n* is $p_1^{2[k_1/2]}...p_m^{2[k_m/2]}$, the square root of which is: p_1

$^{[k_1/2]}...p_m^{[k_m/2]}$, where $[z]$ denotes the integer part of fraction z. The pairs of integers dividing n are of the form:

$$(a,b) = (p_1^{x_1}...p_m^{x_m}, p_1^{k_1 - x_1}...p_m^{k_m - x_m})$$

and $a|b$ if for all i, $x_i =< k_i - x_i$, ie. $x_i =< k_i/2$. Therefore, each x_i can be $0,1,2,...,[k_i/2]$, and:

$$f(n) = ([k_1/2] + 1)([k_2/2] + 1)...([k_m/2] + 1) = tau(p_1^{[k_1/2]}...p_m^{[k_1/2]}) = tau(s(n)),$$

using Theorem 273 from [4]. QED

Proof of Theorem 1.
Suppose that a sets a record for f. Therefore, $f(a) > f(1), f(a) > f(2), ..., f(a) > f(a-1)$, and by lemma 1, this means that $tau(s(a)) > tau(s(1)), tau(s(a)) > tau(s(2)), ..., tau(s(a)) > tau(s(a-1))$. Suppose now that c^2 is the largest square less than or equal to a. Then we see that:

$$\begin{gathered} tau(s(a)) > tau(s(1)) = tau(1) \\ tau(s(a)) > tau(s(4)) = tau(2) \\ \vdots \quad \vdots \\ tau(s(a)) > tau(s((c-1)^2)) = tau(c-1) \end{gathered}$$

If $a > c^2$, the largest square dividing a will be less than c^2 and $s(a) < c$. But then, $s(a) = c - k$ for some k, and $tau(s(a)) = tau(c-k)$, which is a contradiction. Hence $a = c^2$, $s(a) = c$, and $tau(c) > tau(c - i)$ for all $i < c$, which makes c a highly composite number, and a the square of a highly composite number.

Suppose now that b is a highly composite number, and $a=b^2$. Therefore, $s(a) = b$, and, as b is highly composite, if, for some k, $tau(s(a-k)) > tau(s(a))$, then $s(a-k) > s(a) = b$, which is impossible. Hence, for all $k < a$, $tau(s(a)) > tau(s(a - k))$, and by lemma 1, $f(a) > f(a - k)$, thus a sets a record for f. QED

Coincidentally, the previous time there was a similar confusion over a machine invented concept, Douglas Lenat, who wrote the AM program, [11], thought for a while that what he called maximally divisible numbers were a machine invention. These turned out to be the highly composite numbers we've discussed here, which were originally developed by Ramanujan, [12].

This time, we will only claim that it is possible that the function f above was invented by HR, and that it is possible that, while the concept of the squares of highly composite numbers may have been looked at before, HR may have been the first to define them as setting the record for f. It was fortunate that tau numbers had not been added to the encyclopedia, because we may have decided not to develop them. However, the story of refactorable/tau numbers emphasises the need for databases of mathematical knowledge such as the Encyclopedia of Integer Sequences, [9], which can be used by people and

computers alike to check the novelty of inventions.

Abstract: Let the integer sequence A be constructed by the greedy algorithm as follows: Set a[0]=0 and, for n>0, choose a[n] to be the smallest integer greater than a[n-1] such that no member of s={a[0],..., a[n]} is the average of three other members of s. A simple alternative description of A is given in terms of its representation in base 4.

1. Introduction.

It is well known that some sequences which are difficult to calculate directly from their definition are quite easy to compute by an alternative method based on the form of their terms when written in a certain number base. An example, given in [1, Sec. E10], is the integer sequence S containing no 3-term arithmetic progression, constructed by the greedy algorithm as follows: Set a[0]=0. Each subsequent term a[n], for n>0, is chosen to be the least integer greater than a[n-1] so that a[0],a[1], ..., a[n] does not contain a 3-term arithmetic progression. This produces the sequence

0, 1, 3, 4, 9, 10, 12, 13, 27, 28, 30, 31, 36, 37, 39, 40, 81, 82, ...

which in base 3 is

0, 1, 10, 11, 100, 101, 110, 111, 1000, 1001, 1010, 1011, 1100, 1101, 1111, 10000, 10001, ...

Thus it appears that S is the sequence of positive integers that do not contain 2 when written in base 3, and this can easily be shown to be the case.

No equally simple way seems to exist for describing the analogous greedy sequence constructed so as to

contain no 4-term arithmetic progression. It turns out, however, that further progress in this direction can be made if we view the above sequence S not as one containing no 3-term arithmetic progression, but instead as one in which no term is the average of two others, an obviously equivalent condition. Additionally, we can restate the condition that an integer N contains no 2 when written in base 3 as the condition that N = M + r where M contains only 0's and 1's in base 3, and ends in 0, with r = 0 or 1. We pursue this idea in the next section.

2. A Nonaveraging Sequence.

Erdös and Straus [2] define a nonaveraging set A by the property that no member shall be the average of any subset of A with more than one element. (See also [1, Sec. C16]). It is straightforward to carry this concept over to integer sequences. Here we consider the less restrictive case of the integer sequence A defined by the greedy algorithm by a[0] = 0 and, for n>0, a[n] is the least integer such that no member of S = {a[0], a[1],..., a[n]} is the average of three other members of S. A computer program was written to calculate the terms of A, finding

0, 1, 2, 3, 4, 12, 13, 14, 15, 16, 48, 49, 50, 51, 52, 60, 61, 62, 63, 64, 192, 193, ... ,

which was found to be absent from N. J. A. Sloane's On-Line Encyclopedia of Integer Sequences (http://www.research.att.com./~njas/sequences/). It has recently been added as sequence number A036779 (January 1999).

In an attempt to discover a simple alternative description of this sequence, it was written in base 4, giving

0, 1, 2, 3, 10, 30, 31, 32, 33, 100, 300, 301, 302, 303, 310, 330, 331, 332, 333, 1000, 3000, 3001, ...

Each base 4 digit occurs in the terms of this sequence, so clearly no explanation will be as simple as the one in the previous section. However, just as in the terms shown, it was found that if N is any one of the first several hundred terms of A, then M and r exist such that N = M + r where M, when written in base 4, ends with 0, and contains only the digits 0 and 3, and where r is 0,1,2,3 or 4. In addition, each of the first several hundred integers which may be so written is found to be a term of the sequence. The general validity of this characterization will now be established.

3. Nonaveraging Property Characterized by Form in Base 4.

We define two sequences as follows:
(D1) Let A be the integer sequence defined by the greedy algorithm, with a[0] = 0 and a[n] chosen to be the smallest integer greater than a[n-1] such that no member of {a[0], a[1],..., a[n]} is the average of three other members.

(D2) Let B be the subsequence of the nonnegative integers N that can be written as N = M + r, where the base 4 representation of M ends with 0 and contains only the digits 0 and 3, and where r is 0, 1, 2, 3, or 4.

The following lemma shows that B has the nonaveraging property of A.

Lemma 1. *There does not exist a term of B which is the average of three other terms of B.*
Proof (by contradiction). Suppose that there do exist four distinct terms t, u, v, and w of B such that t is the average of u, v, and w, i.e. 3t=u+v+w. Write t in the base 4 form described in (D2) above, that is, in the form

$$t = M1 + r1 = t_{k1}t_{k1-1}...t_2t_1 + r1$$

where the t_i are the digits of M1 when written in base 4, with t_{k1}=3, t_1=0, all other t_i=0 or 3, and r1 in [0...4]. Write each of u = M2 + r2, v = M3 + r3, and w = M4 + r4 in the corresponding form, i.e. u = $u_{k2}...u_1$ + r2, etc. We now write T = 3t, *without* reducing digits mod 4, to get

$$T = 3t = T_{k1}T_{k1-1}...T_2T_1 + R$$

where T_{k1} = 9, T_1 = 0, all other T_i = 0 or 9, and R is in [0, 4, 8, 12]. There are now two cases, according to whether R<12 or R=12. If R<12 or, equivalently, R<30(base 4) then, since T = u + v + w, we clearly must have k4 = k3 = k2 = k1 with u_{k1} = v_{k1} = w_{k1} = 3, u_1 = v_1 = w_1 = 0, and for all other i, u_i = v_i = w_i = 0 or 3. In other words, we must have M1, M2, M3, and M4 all equal to a common integer, say N, giving t=N+r1, u=N+r2, v=N+r3, and w=N+r4, where r1, r1, r3, and r4 all have values in 0...4, with r1=(r2+r3 +r4)/3. But this is a contradiction, since it is easily verified that none of the integers 0...4 is the average of three others. On the other hand, if R=12 then either each of r2, r3, and r4 must be 4 thus giving u = v = w, contradicting the distinctness of the terms, or, since R=12=30(base 4), R can be carried into T to give T_j = 3 for some j>1, with all other T_i = 0 or 9 in Eq. (3.2). But this latter situation means that two of u_2, v_2, and w_2 must be 0 or 3, thus requiring that two of u, v, and w must be equal, again contradicting the distinctness of the terms and completing the proof.

The next lemma shows that no additional terms can be inserted into B without violating the nonaveraging property, thus showing that B has the "greedy" property of A.

Lemma 2. *Let n be an integer that is not a term of B. Then there exist three distinct terms u, v, and w of B, each smaller than n, such that u is the average of v, w, and n.*
Proof. Write n in base 4: n = $n_k n_{k-1}...n_2n_1$(base 4). If n_k is 1 or 2 then "carry" that digit to the right by adding 4*n_k to n_{k-1}. It is easy to see that the maximum value of the excess of this sum over one of 3, 6, or 9, is 2. Continue this process to the right on the digits n_i until i = 1, then set r = n_1 followed by n_1 = 0. Clearly r lies in 0...11. We now have n expressed in the form n = D + r = $d_k d_{k-1}...d_2d_1$(base 4) + r,

where $d_1 = 0$, all other $d_i = 0$, 3, 6, or 9, and r is in 0..11. Now, for each i = 2...k, choose v_i and w_i to be 0 or 3 in such a way that $d_i + v_i + w_i = 9$. Direct calculation shows that rv and rw can always be chosen so that r+rv+rw=3ru where ru, rv, and rw are distinct and each in 0...4. Clearly v, w, and u=(v+w+n)/3 are terms of B, and the proof is complete.

As an illustration of the constructive nature of the proof of Lemma 2, consider n = 2500 = 213010(base 4) = 93000(base 4) + 4. Choose v = 3000(base 4) + 1, w = 3000(base 4) + 4. Then u = (99000(base 4) + 9)/3 = 33000(base 4) + 3. Thus u, v, and w are distinct terms of B and u is the average of v, w, and n.

Lemmas (1) and (2), together with the fact that sequences A and B have the same initial terms, lead immediately to our main result, as follows:

Theorem. *If sequences A and B are as defined above in (D1) and (D2), then A=B.*

Another illustration. The theorem allows us to easily determine whether any given positive integer n is a term of the greedy integer sequence A with first term 0 and containing no term which is the average of three other terms. For example, n = 123456789(base 10) = 13112330310111(base 4) does *not* have the required form in base 4 and thus is not a term of A, whereas n = 217105166(base 10) = 30330030030030 (base 4) + 2 does have the required form and thus is a term of A. The determination of these facts by computation directly from the definition of A would appear to be impossible for all practical purposes.

Abstract: We determine, for each positive integer n, the smallest number that can be obtained by starting with $\{1, 2, ..., n\}$ and repeatedly replacing two numbers by the difference of their squares.

0. Introduction

Problem 178 in [V] asks:

> The numbers from 1 to 2001 are written on a sheet of paper. Choose two of these numbers, say a and b, remove them from the list, and add $|a^2 - b^2|$ (the nonnegative difference between their squares) to the list. Repeat this procedure over and over again. Each time, you take away two numbers from the list, square them, and adjoin to the list the nonnegative difference (it might be 0) of their squares. After a number (how many?) of such operations, you will have only one number left on the paper. Can you choose the numbers so that this last remaining number is zero?

(We wish to thank Loren Larson, who is preparing an English version of [V], for this translation.)

The answer is "no", since the number of odd numbers in the set is initially 1001, and its parity never changes. But this led Richard K. Guy [personal communication] to ask the more general question:

> Start with a multiset S of integers. Repeatedly replace two members a and b by $|a^2 - b^2|$, until a single integer remains. How small can the remaining value be?

In this paper we answer this question whenever S has the form $\{1, 2, ..., n\}$ for a positive integer n. We also give some partial results for other intervals.

First, some notation and terminology:

We let $f(a,b) = |a^2 - b^2|$.

If a multiset T can be obtained from a multiset S by repeatedly replacing elements a and b by $f(a,b)$, we will say that T is a reduction of S, or that S can be reduced to T. If T is a singleton, $\{t\}$, we will also say that S can be reduced to t.

If S is a nonempty multiset of integers then we let $r(S)$ be the smallest number such that S can be reduced to $r(S)$.

If n is a positive integer, we write $r(n)$ for $r(\{1, 2, ..., n\})$.

It is easy to find by hand that

$r(1) = 1$,

$r(2) = f(1,2) = 3$,

$r(3) = f(f(1,2), 3) = 0$,

$r(4) = f(f(f(1,2), 3), 4) = 16$,

$r(5) = f(f(0,1), 4) = 15$, where $0 = f(f(2,3), 5)$, and

$r(8) = f(f(f(2,4), f(6,7)), f(0,5)) = 0$, where $0 = f(f(1,3), 8)$.

By exhaustive computer search, we also obtain

$r(6) = f(f(f(1,4), f(3,5)), f(2,6)) = 63$ and

$r(7) = f(f(0,1), 3) = 8$, where $0 = f(f(f(4,5), 7), f(2,6))$.

(Unfortunately, we know of no succinct proof of these two values.)

As we will prove, the sequence continues as shown here:

n	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
$r(n)$	1	3	0	16	15	63	8	0	3	1	0	0	1	3	0	4	3	3	4	0

This is sequence A038122 in [EIS].

Our main result states that, for n greater than or equal to 8, the sequence is periodic with period 12.

Theorem: For $n>0$, let $s(n)$ be defined by the table below:

n mod 12	0	1	2	3	4	5	6	7	8	9	10	11
$s(n)$	0	1	3	0	4	3	3	4	0	3	1	0

Then, for n not equal to 4, 5, 6, or 7, we have $r(n) = s(n)$. Furthermore, $r(4) = 16$, $r(5) = 15$, $r(6) = 63$, and $r(7) = 8$.

Our proof consists of three parts: First, we prove congruences for $r(S)$ for an arbitrary multiset S, which will imply that $r(n) >= s(n)$. Next, we will show that $r(n+24) <= r(n)$ for all n. Finally, we will compute the values of $r(n)$ for n from 1 to 23 and from 28 to 31. From this information, our result will follow by induction.

1. Congruences

Lemma 0: Suppose that $|S| >= 2$. If the number of odd elements of S is even, then $r(S)$ is divisible by 4. Otherwise, $r(S)$ is odd.

Note: The first part of this is not true if $|S| = 1$; e.g. $r(\{2\}) = 2$ is not divisible by 4.

Proof: As noted earlier, the parity of the number of odd elements doesn't change when we replace a and b by $f(a,b)$. So in the first case, $r(S)$ is even. But a difference of squares can't be congruent to 2 (mod 4), so $r(S)$ must be divisible by 4. In the second case, $r(S)$ must be odd. QED

Lemma 1: If the number of elements of S which are not divisible by 3 is even, then $r(S)$ is divisible by 3. Otherwise, $r(S)$ is not divisible by 3.

Proof: If a and b are either both divisible by 3 or both not divisible by 3, then $f(a,b)$ is divisible by 3. Otherwise it is not. In either case, replacing a and b by $f(a,b)$ does not change the parity of the number of elements which are not divisible by 3. So if that number is even, then $r(S)$ is divisible by 3; otherwise it is not. QED

Applying Lemmas 0 and 1 to the case $S = \{1, 2, ..., n\}$, we find the following information about $r(n)$ modulo 6 or 12:

n mod 12	$r(n)$ mod 2 or 4	$r(n)$ mod 3	$r(n)$ mod 6 or 12

0	0 (mod 4)	0	0 (mod 12)
1	1 (mod 2)	1 or 2	1 or 5 (mod 6)
2	1 (mod 2)	0	3 (mod 6)
3	0 (mod 4)	0	0 (mod 12)
4	0 (mod 4)	1 or 2	4 or 8 (mod 12)
5	1 (mod 2)	0	3 (mod 6)
6	1 (mod 2)	0	3 (mod 6)
7	0 (mod 4)	1 or 2	4 or 8 (mod 12)
8	0 (mod 4)	0	0 (mod 12)
9	1 (mod 2)	0	3 (mod 6)
10	1 (mod 2)	1 or 2	1 or 5 (mod 6)
11	0 (mod 4)	0	0 (mod 12)

From this table we obtain:

Lemma 2: $r(n) >= s(n)$ for all $n >= 1$.

2. The inductive step

Next we show that information about $r(S)$ and $r(T)$ can sometimes give information about $r(S \text{ union } T)$:

Lemma 3: If $r(T) = 0$ and either 0 or 1 is an element of S, then $r(S \text{ union } T) <= r(S)$.

Proof: Since T can be reduced to 0, S union T can be reduced to S union {0}. If 0 is in S then S union {0} contains two 0's; replacing them by $f(0,0) = 0$ reduces S union {0} to S. Similarly, if 1 is in S then replacing 0 and 1 by $f(0,1) = 1$ reduces S union {0} to S. Finally, S can be reduced to $r(S)$, so we conclude that S union T can be reduced to $r(S)$. Hence $r(S \text{ union } T) <= r(S)$. QED

Lemma 4: For any integer n, $r([n,n+23]) = 0$.

Here $[x,y]$ denotes the set of integers $>= x$ and $<= y$.

Proof: First we replace each pair $n+i$ and $n+23-i$ ($0 <= i <= 11$) by the difference of their squares, namely $f(n+i, n+23-i) = (23-2i)\,|2n+23|$. Letting $m = |2n+23|$, we have reduced $[n,n+23]$ to $\{m, 3m, 5m, ..., 23m\}$.

Next, we reduce this set to {0,0} via

$$f(f(3m,7m), f(9m,11m)) = 0$$

and

$$f(f(f(m,5m), f(13m,15m)), f(f(17m,19m), f(21m,23m))) = 0.$$

Finally, reducing {0,0} to $f(0,0)=0$ completes the proof. QED

Combining Lemmas 3 and 4 yields:

Lemma 5: For $n >= 25$, $r(n) <= r(n\text{-}24)$.

Proof: Apply Lemma 3 with $S = [1,n\text{-}24]$ and $T = [n\text{-}23,n]$: By Lemma 4 with n changed to n-23, $r(T) = 0$. Hence

$r(n) = r(S \text{ union } T) <= r(S) = r(n\text{-}24)$. QED

Now suppose that $n >= 25$ and that $r(n\text{-}24) = s(n\text{-}24)$. Then

$r(n) <= r(n\text{-}24) = s(n\text{-}24) = s(n)$.

But, by Lemma 2, $r(n) >= s(n)$, so $r(n) = s(n)$. So if the Theorem is true for a value of n other than 4, 5, 6, or 7, then it is also true for n+24. So to complete the proof, we need only show that it is true for $n <= 24$ and for $28 <= n <= 31$. We've already discussed the values of $r(n)$ for $n <= 8$; in the next section we prove the remaining values.

3. Specific values of *r*(*n*)

Each reduction below shows that $r(n) <= s(n)$ for one value of n. Combining this with Lemma 2 gives the stated equality.

In each reduction, we explicitly show the zeros that occur as intermediate values. For example, for $r(10)$, we first reduce {4,5,9} to 0, then reduce {0,6,8,10} to 0, then reduce {0,2,3,7} to 0, and finally reduce {0,1} to 1.

Verifying these reductions is easy, although in some cases finding them was not, since the size of the problem grows rapidly with the size of the set. Specifically, the number of possible reductions for a set of n elements is $(2n\text{-}3)!! = 1 * 3 * 5 * ... * (2n\text{-}3)$. To see this by induction on n, suppose that we have a reduction on a set S of n elements. Then we can add another element a to it by changing some X to $f(X,a)$, where X is either one of the original n elements, or one of the n-1 expressions of the form $f(Y,Z)$ that occur in the original reduction. So there are $2n$-1 ways to add the new element for each reduction of S. (This is not a new result; it is essentially Problem 1.36 of [L].)

With the computer resources that we have available, we can do an exhaustive search of the roughly 14 billion reductions of a set of 12 elements in about 3.5 hours. For larger sets, we made reasonable guesses about initial steps which reduced certain subsets to 0, and then used computer searches on the reduced sets. Sometimes we had to try several different combinations of initial steps before finding one that worked.

```
r(9)  = 3,  because
        f(f(f(f(3,4), 6), f(7,8)), f(5,9)) = 0  and

$f(f(0,6), f(8,10)) = 0,$ and
$f(f(f(1,2), 0), f(4,5)) = 0.$

$r(12) = 0,$ because
$f(f(f(3,4), 1), f(f(6,7), 11)) = 0$ and
$f(f(f(2,5), f(9,10)), f(8,12)) = 0.$

$r(13) = 1,$ because
$f(f(3,7), f(9,11)) = 0,$
$f(f(0,6), f(8,10)) = 0,$
$f(f(0,5), f(12,13)) = 0,$
$f(f(0,2), 4) = 0,$ and
$f(0,1) = 1.$

$r(14) = 3,$ because
$f(f(5,10), f(11,14)) = 0,$
$f(f(6,7), 13) = 0,$
$f(f(f(f(3,4), 8), 12), f(0,9)) = 0,$ and
$f(f(0,1), 2) = 3.$

$r(15) = 0,$ because
$f(f(1,4), f(7,8)) = 0,$
$f(f(2,5), f(10,11)) = 0,$
$f(f(3,6), f(13,14)) = 0,$ and
$f(f(0,9), f(12,15)) = 0.$

$r(16) = 4,$ because
$f(f(5,10), f(11,14)) = 0,$
$f(f(6,7), 13) = 0,$
$f(f(1,3), 8) = 0,$
$f(f(0,9), f(12,15)) = 0,$
$f(f(0,4), 16) = 0,$ and
$f(0,2) = 4.$

$r(17) = 3,$ because

$f(f(4,7), f(16,17)) = 0,$
$f(f(f(11,12), f(13,14)), f(5,15)) = 0,$
$f(f(0,3), 9) = 0,$
$f(f(0,6), f(8,10)) = 0,$ and
$f(f(0,1), 2) = 3.$

$r(18) = 3,$ because
$f(f(4,12), f(14,18)) = 0,$
$f(f(5,9), f(13,15)) = 0,$
$f(f(f(f(6,7), 11), f(8,10)), f(f(0,3), f(16,17))) = 0,$ and
$f(f(0,1), 2) = 3.$

$r(19) = 4,$ because
$f(f(f(11,12), f(14,15)), f(f(9,10), 7)) = 0,$
$f(f(8,13), f(16,19)) = 0,$
$f(f(1,6), f(17,18)) = 0,$
$f(f(0,3), f(4,5)) = 0,$ and
$f(0,2) = 4.$

$r(20) = 0,$ because
$f(f(f(11,14), f(17,18)), f(f(10,13), 19)) = 0,$
$f(f(9,15), f(16,20)) = 0,$
$f(f(1,4), f(7,8)) = 0,$ and
$f(f(f(f(f(0,2), 3), 6), 5), f(0,12)) = 0.$

$r(21) = 3,$ because
$f(f(f(10,11), 6), f(f(13,14), 18)) = 0,$
$f(f(f(3,5), 17), f(4,7)) = 0,$
$f(f(9,15), f(16,20)) = 0,$
$f(f(8,12), f(19,21)) = 0,$ and
$f(f(0,1), 2) = 3.$

$r(22) = 1,$ because
$f(f(f(f(2,4), 13), 20), f(f(f(3,5), 16), 15)) = 0,$
$f(f(7,11), f(f(9,10), 17)) = 0,$
$f(f(8,12), f(19,21)) = 0,$
$f(f(6,14), f(18,22)) = 0,$ and
$f(0,1) = 1.$

$r(23) = 0,$ because
$f(f(f(10,11), f(13,14)), f(6,18)) = 0,$
$f(f(f(1,3), f(4,5)), 17) = 0,$
$f(f(9,15), f(16,20)) = 0,$
$f(f(8,12), f(19,21)) = 0,$ and
$f(f(2,7), f(22,23)) = 0.$

$r(24) = 0$, by Lemma 4 with $n=1$.

$r(28) = 4$, because
$f(f(7,14), f(23,26)) = 0$,
$f(f(f(18,19), f(21,24)), f(f(22,25), f(27,28))) = 0$,
$f(f(f(f(3,4), 6), 1), f(f(9,10), f(11,12))) = 0$,
$f(f(5,13), f(16,20)) = 0$,
$f(f(0,8), f(15,17)) = 0$, and
$f(0,2) = 4$.

$r(29) = 3$, because
$f(f(f(19,20), f(22,25)), f(f(23,26), f(28,29))) = 0$,
$f(f(f(3,6), 12), f(f(10,14), f(15,18))) = 0$,
$f(f(f(5,7), 21), f(11,16)) = 0$,
$f(f(4,13), f(24,27)) = 0$,
$f(f(8,9), 17) = 0$, and
$f(f(0,1), 2) = 3$.

The values of $r(30)$ and $r(31)$ are obtained from those of $r(18)$ and $r(19)$ with the help of Lemma 3:

$r([19,30]) = 0$, because
$f(f(f(19,20), 21), f(f(24,25), f(29,30))) = 0$ and
$f(f(0,28), f(f(22,23), f(26,27))) = 0$;
therefore $r(30) = r(18) = 3$.

$r([20,31]) = 0$, because
$f(f(f(20,24), 29), f(f(21,25), f(30,31))) = 0$ and
$f(f(0,28), f(f(22,23), f(26,27))) = 0$;
therefore $r(31) = r(19) = 4$.

This completes the proof of the Theorem.

4. Translation invariant reductions

In Lemma 4 we showed that $r(\{n, n+1, ..., n+23\}) = 0$ for every n. There are other results of this type involving smaller sets. For example,

$$r(\{n-6, n-2, n-1, n+1, n+2, n+6\}) = f(f(f(n-1,n-2), n-6), f(f(n+1,n+2), n+6)) = 0; \quad (4.0)$$

$$r(\{n\text{-}5,\ n\text{-}4,\ n\text{-}2,\ n\text{-}1,\ n\text{+}1,\ n\text{+}2,\ n\text{+}4,\ n\text{+}5\}) = f(f(f(n\text{-}5,n\text{-}4),\ f(n\text{-}2,n\text{+}1)),\ f(f(n\text{-}1,n\text{+}2),\ f(n\text{+}4,n\text{+}5))) = 0. \quad (4.1)$$

(Equation (4.1) with n=23 and 24 was used in proving the values of $r(28)$ and $r(29)$.)

Each of these examples is symmetric: There is some integer k such that the reduction is unchanged if we change $n+i$ to $n+k-i$ for each i. But there are also asymmetric examples, such as

$$r(\{n,\ n\text{+}1,\ n\text{+}3,\ n\text{+}5,\ n\text{+}12,\ n\text{+}13,\ n\text{+}18,\ n\text{+}20\}) = f(f(f(n,n\text{+}5),\ f(n\text{+}1,n\text{+}12)),\ f(f(n\text{+}3,n\text{+}13),\ f(n\text{+}18,n\text{+}20))) = 0. \quad (4.2)$$

Open Problem 0: Find necessary and sufficient conditions on a multiset of integers $\{a_1, ..., a_k\}$ so that $r(\{n+a_1, ..., n+a_k\}) = 0$ for all n.

An obvious necessary condition is that both the number of even elements and the number of odd elements be even; otherwise we could pick n so that Lemma 0 would rule out a reduction to 0. Similarly, the number of elements in each congruence class mod 3 must be even.

If the equation $r(\{n+a_1, ..., n+a_k\}) = 0$ is not true for all n, then there are only finitely many values of n for which it is true. To see this, note that the result of any particular reduction of the set has the form $|p(n)|$ for some polynomial p. If one of these polynomials is identically zero, then $r(\{n+a_1, ..., n+a_k\}) = 0$ for all n. Otherwise, the equation is true only if n is one of finitely many roots of finitely many polynomials.

Beyond that, we have little information about this problem. Even for intervals, we haven't completely solved it. The mod 2 and mod 3 restrictions imply that if every interval of length k can be reduced to 0, then k must be a multiple of 12. We hoped for a while that every interval of length 12 could be reduced to 0; that would have simplified the proof of the Theorem. We found such reductions for the intervals $[n,n+11]$ with n = -5 to 14, 16, 17, 19, 20, and 26. However, an exhaustive computer search showed that this is not true in general; in particular the interval cannot be reduced to 0 for n = 15, 18, or 21 to 25.

For larger multiples of 12, we know from Lemma 4 that every interval of length 24 can be reduced to 0. We now show that the same is true for intervals of length 60: Starting with $[n,n+59]$, we first use (4.0) with n replaced by $n+6$ and $n+53$, reducing both

$\{n, n+4, n+5, n+7, n+8, n+12\}$ and

$\{n+47, n+51, n+52, n+54, n+55, n+59\}$

to 0. Next, for i = 1 to 3, 6, 9 to 11, and 13 to 29, we reduce $\{n+i,n+59-i\}$ to $(59-2i)m$, where $m = |2n+59|$. This gives us the set

$\{m, 3m, 5m, 7m, 9m, 11m, 13m, 15m, 17m, 19m, 21m, 23m, 25m, 27m,$

$29m, 31m, 33m, 37m, 39m, 41m, 47m, 53m, 55m, 57m\}$.

Finally, we use

$f(f(5m,29m), f(47m,55m)) = 0,$

$f(f(7m,19m), f(37m,41m)) = 0,$

$f(f(17m,27m), f(53m,57m)) = 0,$

$f(f(23m,31m), f(33m,39m)) = 0,$

and

$f(f(f(m,13m), f(3m,9m)), f(f(11m,15m), f(21m,25m))) = 0$

to complete the reduction to 0.

In conjunction with the result for intervals of length 24, this implies that every interval whose length is a multiple of 12, except for 12 itself, and with the possible exception of 36, can be reduced to 0. This leaves us with:

Open Problem 1: Can every interval of length 36 be reduced to 0?

Abstract: In the "tennis ball" problem we are given successive pairs of balls numbered (1,2), (3,4),... At each stage we throw one ball out of the window. After *n* stages some set of *n* balls is on the lawn. We find a generating function and a closed formula for the sequence 3,23,131,664,3166,14545,65187,287060,1247690,..., the *n*-th term of which gives the sum over all possible arrangements of the total of the numbers on the balls on the lawn. The problem has connections with "bicolored Motzkin paths" and the ballot problem.

1. Introduction.

The tennis ball problem goes as follows. At the first turn you are given balls numbered 1 and 2. You throw one of them out the window onto the lawn. At the second turn balls numbered 3 and 4 are brought in and now you throw out on the lawn any of the three balls in the room with you. Then balls 5 and 6 are brought in and you throw out one of the four available balls. The game continues for *n* turns. The first question is how many different arrangements on the lawn are possible. It is easy to see that there are 2, 5 and 14 possibilities after 1, 2 and 3 turns. This suggests the Catalan numbers which turns out to be the

case. A more delicate question is "what is the total sum of the balls on the lawn over all these possibilities"? Here the first few terms are 3, 23, 131 and 664. As an example consider the five possibilities after two turns. They are $\{1,2\}$, $\{1,3\}$, $\{1,4\}$,$\{2,3\}$ or $\{2,4\}$.The total sum is $(1+2)+(1+3)+(1+4)+(2+3)+(2+4)=23$.

We will find both a generating function and a closed formula for this sequence. First we return to the first question and transform it to a question about paths.

- Consider paths in the plane which satisfy the following conditions:
- The possible steps are $U = Up = (1,1)$, $D = Down = (1,-1)$ and $Level = (1,0)$.We allow the level steps to be one of two colors, *L* or *l*.
- The paths start at $(0,0)$ and consist of *n* steps.
- The paths never go below the *x*-axis.

  Such paths are called **bicolored Motzkin paths** (see [5]). If there had been only one kind of level step and the paths ended on the *x-axis* we would have regular Motzkin paths (see [1],[3], or [7] for more information on Motzkin paths and Motzkin numbers).

Let $b(n,k)$ be the number of possible paths that end at (n,k). Here is a table of small values

$n\backslash k$	0	1	2	3	4
0	1	0	0	0	0
1	2	1	0	0	0
2	5	4	1	0	0
3	14	14	6	1	0
4	42	48	27	8	1

We can make three observations. One is that with the four kinds of steps we get the recursion

$$b(n+1,k) = b(n,k-1) + 2b(n,k) + b(n,k+1).$$

This holds for $k, n \geq 0$ if we specify that $b(0,0) = 1$ and $b(n,-1) = 0$. Both conditions make sense in terms of these paths.

Secondly we have

$$b(n,k) = \frac{k+1}{n+1}\binom{2n+2}{n-k}.$$

Given the recursion, this is easily established by induction.

Thirdly $b(n,0) = \frac{1}{n+2}\binom{2(n+1)}{n+1}$, the $(n+1)^{st}$ Catalan number (see [6] and [7] for different proofs).

Now we return to the balls on the lawn after n turns. Let us look at a typical example after 6 turns.

$$\underset{l}{12'} \;/\; \underset{U}{3'4'} \;/\; \underset{L}{5'6} \;/\; \underset{L}{7'8} \;/\; \underset{D}{9,10} \;/\; \underset{l}{11,12'}$$

The balls on the lawn are denoted by "l". As we read from left to right one pair at a time, we must always have as many or more pairs with both balls selected as with no balls selected with equality at the end. If both balls are selected mark the pair with a *U*, if neither is selected mark with a *D*, if the odd member is the one selected use an *L*, if the even number was selected then use an *l*. This sets up an obvious correspondence with the bicolored Motzkin paths ending at height zero and this shows that the number of possibilities after *n* turns is the Catalan number C_{n+1}.

We now want to shift back to subdiagonal paths from $(0,0)$ to $(n+1,n+1)$ using unit east and north steps. If we number the steps along each such path starting at the origin using the numbers to 2*n* +1, then the numbers of the horizontal steps correspond to the numbers of the balls on the lawn except that we ignore the initial horizontal step numbered 0. All subdiagonal paths must go from $(0,0)$ to $(1,0)$ at the first step so let us look on $(1,0)$ as our starting point and $(n+1,n)$ as the terminal point. We then look at steps in pairs to set up a correspondence with bicolored Motzkin paths

$$\begin{array}{lcl} EE & \leftrightarrow & U \\ EN & \leftrightarrow & L \\ NE & \leftrightarrow & l \\ NN & \leftrightarrow & D \end{array} \quad \text{where } E=(0,1) \text{ and } N=(1,0)$$

To evaluate the sum over all possible sets of balls on the lawn takes a bit more doing and its worthwhile to separate out some definitions and lemmas first.

---

2. Definitions and notation.

The n^{th} Catalan number is $C_n = \frac{1}{n+1}\binom{2n}{n}$ .The generating function for the sequence of Catalan numbers is $C = C(z) = \sum_{n=0}^{\infty} C_n z^n = \frac{1-Q}{2z}$ where $Q = \sqrt{1-4z}$ .Similarly $B = B(z) = \sum_{n=0}^{\infty} \binom{2n}{n} z^n = \frac{1}{Q}$ is the generating function for the sequence of central binomial coefficients.

The following lemmas can be proved combinatorially but instead we refer to Concrete Mathematics [4], page 203, formulas (5.80) and (5.82) for the first two lemmas and leave the others as exercises.

Lemma 1

$$C^d = \sum_{j=0}^{\infty} \frac{d}{2j+d}\binom{2j+d}{j} z^j$$

Lemma 2

$$C^d = \sum_{j=0}^{\infty} \frac{d}{j+d}\binom{2j+d-1}{j+d-1} z^j$$

Lemma 3

$$BC^d = \sum_{j=0}^{\infty} \binom{2j+d}{j} z^j$$

Lemma 4

$$B = \frac{C}{1 - zC^2} \text{ or alternatively } \frac{1}{1 - zC^2} = \frac{B}{C}$$

Lemma 5

$$2B = C\,(1 + B)$$

Lemma 6

$$B^3 = \sum_{n=0}^{\infty} (2n+1) \binom{2n}{n} z^n$$

Lemma 7

The number of subdiagonal paths from $(0, 0)$ to (i, j) will be denoted $N\,(i, j)$ and

$$N\,(i, j) = \frac{i + 1 - j}{i + 1} \binom{i + j}{i}.$$

This is the cornerstone result about ballot numbers and a reference which summarizes this and much of the related literature is[2].

We now want to embark on the main computation. Note first that

$$M_n = \sum_{i=0}^{n} \sum_{j=0}^{i} N\,(i, j) \cdot (i + j) \cdot N\,(n + 1 - j, n - i)\,.$$

Before launching into the evaluation lets look at each term. There are $N\,(i, j)$ paths from $(0, 0)$ to (i, j) and $N\,(n + 1 - j, n - i)$ paths from $(i + 1, j)$ to $(n + 1, n + 1)$.What does it mean for a path to have arrived at (i, j)? Of the balls $\{1, 2, \ldots, i + j - 1\}$, *i*-1 of them are on the lawn and *j* of them are to stay in the room. The horizontal step $(i, j) \to (i + 1, j)$ indicates that ball

number *i*+*j* is to be on the lawn and hence the term $(i+j)$ .By Lemma 7 we then get

$$M_n = \sum_{i=0}^{n} \sum_{j=0}^{i} \frac{i+1-j}{i+1} \binom{i+j}{i} \cdot (i+j) \cdot \frac{i+2-j}{n+2-j} \binom{2n+1-i-j}{n+1-j}$$

We want to find a closed form for the generating function

$$M(z) := \sum_{n=0}^{\infty} M_n z^n$$

If we set *n*=*m*+*i* and then *i*=*j*+*d* we obtain

$$M(z) = \sum_{m=0}^{\infty} \sum_{j=0}^{\infty} \sum_{d=0}^{\infty} \frac{d+1}{j+d+1} \binom{2j+d}{j} (2j+d) \times$$

$$\times \frac{d+2}{m+d+2} \binom{2m+1+d}{m+d+1} z^{m+j+d}.$$

We sum on *m* first; then invoke Lemma 2.

$$\begin{aligned} M(z) &= \sum_{j=0}^{\infty} \sum_{d=0}^{\infty} \frac{d+1}{j+d+1} \binom{2j+d}{j} (2j+d)\, z^{j+d} \times \\ &\qquad \times \sum_{m=0}^{\infty} \frac{d+2}{m+d+2} \binom{2m+1+d}{m+d+1} z^m \\ &= \sum_{j=0}^{\infty} \sum_{d=0}^{\infty} \frac{d+1}{j+d+1} \binom{2j+d}{j} (2j+d)\, z^{j+d} C^{d+2} \end{aligned}$$

By rewriting 2*j*+*d*=2*j*+*d*+1-1 we get $M(z) = P - R$where

$$P = \sum_{j=0}^{\infty} \sum_{d=0}^{\infty} (2j+d+1) \frac{d+1}{j+d+1} \binom{2j+d}{j} z^{j+d} C^{d+2}$$

and

$$R = \sum_{j=0}^{\infty} \sum_{d=0}^{\infty} \frac{d+1}{j+d+1} \binom{2j+d}{j} z^{j+d} C^{d+2}.$$

However, with the aid of Lemmas 3 and 4, we obtain

$$\begin{aligned}
P &= \sum_{d=0}^{\infty} (d+1) C^{d+2} \sum_{j=0}^{\infty} \frac{2j+d+1}{j+d+1} \binom{2j+d}{j} z^{j+d} \\
&= \sum_{d=0}^{\infty} (d+1) C^{d+2} z^d \sum_{j=0}^{\infty} \binom{2j+d+1}{j} z^j \\
&= \sum_{d=0}^{\infty} (d+1) C^{d+2} z^d B C^{d+1} \\
&= BC^3 \sum_{d=0}^{\infty} (d+1) C^{2d} z^d \\
&= BC^3 \frac{1}{(1-zC^2)^2} = BC^3 \left(\frac{B}{C}\right)^2 = B^3 C.
\end{aligned}$$

For the second term we have, via Lemmas 2 and 4,

$$\begin{aligned}
R &= \sum_{j=0}^{\infty} \sum_{d=0}^{\infty} \frac{d+1}{j+d+1} \binom{2j+d}{j} z^{j+d} C^{d+2} \\
&= \sum_{d=0}^{\infty} C^{d+2} z^d \sum_{j=0}^{\infty} \frac{d+1}{j+d+1} \binom{2j+d}{j} z^j \\
&= \sum_{d=0}^{\infty} C^{d+2} z^d C^{d+1} \\
&= C^3 \frac{1}{1-zC^2} = C^3 \cdot \frac{B}{C} = C^2 B
\end{aligned}$$

Thus $M(z) = B^3C - C^2B.$

---

3. Remarks.

1.

$$M(z) = \frac{C^3B^3}{z}\left(1+\frac{2}{B}\right) = \frac{C^3}{z(1-4z)}(B+2).$$

2.

$$M_n = \frac{2n^2+5n+4}{n+2}\binom{2n+1}{n} - 2^{2n+1}$$

3.

There is also a connection with hypergeometric functions.

$$C^d = {}_1F_2\left(\frac{d}{2}, \frac{d+1}{2}; d+1; 4z\right)$$

and

$$BC^d = {}_1F_2\left(\frac{d+1}{2}, \frac{d+2}{2}; d+1; 4z\right)$$

The first and third of these remarks can be shown by routine algebraic manipulations and the second follows from the first as follows:

$$\begin{aligned} zC^3B^3\left(1+\frac{2}{B}\right) &= \frac{zC^3}{Q^3}(1+2Q) = \frac{z}{Q^3}(1+2Q)\left(\frac{1-Q}{2z}\right)^3 \\ &= \frac{1}{8z^2Q^3}\left(1-Q-3Q^2+5Q^3-2Q^4\right) \\ &= \frac{1}{2z^2Q^3}\left(-1+7z-8z^2+Q-5Qz\right) \\ &= \tfrac{1}{2}\left[-\tfrac{B^3}{z^2}+7\tfrac{B^3}{z}-8B^3+\tfrac{1}{z^2}B^2-5\tfrac{B^2}{z}\right]. \end{aligned}$$

since Q^2=1-4z. But $B^2=\sum_{n=0}^{\infty}4^n z^n$ while $B^3=\sum_{n=0}^{\infty}(2n+1)\binom{2n}{n}$.Thus extracting n^{th} terms yields

$$\begin{aligned} M_n &= \frac{1}{2}\Bigg[-(2n+5)\binom{2n+4}{n+2}+7(2n+3)\binom{2n+2}{n+1} \\ &\qquad -8(2n+1)\binom{2n}{n}+4^{n+2}-5\cdot 4^{n+1}\Bigg] \\ &= \frac{2n^2+5n+4}{n+2}\binom{2n+1}{n}-2^{2n+1}. \end{aligned}$$

Two other remarks can be made here. First, an asymptotic result,

$$M_n \sim 4^n\left(4\sqrt{\frac{n}{\pi}}-2\right).$$

Second, the expected value of the balls on the lawn is $\frac{n(4n+5)}{6}$ if we assume each available ball is equally likely to be picked at each turn.

Problem 19(s) of reference [7] is succinct but less colorful. It asks one to show that the Catalan numbers count sequences of positive integers such that $a_1 < a_2 < \cdots < a_n$ and $a_i \le 2i$.The references there point out a connection with an indexing of the weights of the $(n-1)\,st$ fundamental representation of the symplectic group $Sp(2n-2,\mathbf{C})$.

The problem was brought to our attention by Ralph Grimaldi, see [6], who refers to the logic text [8] where it is pointed out that after an infinite number of turns the balls remaining in the room can be either the empty set, a finite set of arbitrary size or even an infinite set such as all the even numbered balls.

Abstract: We study rectangular and trapezoidal arrangements of identical objects and answer the following questions. How many such arrangements are possible with *n* objects? For which numbers *k*, does there exist a number *n* of objects that allows exactly *k* such arrangements? In those cases where it exists, what is the least such number *n*?

1. Introduction

Dehaene shows in his excellent book *The Number Sense* [Deh97] that children have considerably more built-in knowledge about numbers than previously assumed. Careful experiments have overthrown several of Piaget's theories about the cognitive development of children. For mathematically inclined parents, this will not come as a surprise, because they are not afraid to challenge their children from an early age on. This article was inspired by such a challenge.

O O O O O
O O O O O
O O O O O

Figure 1: Rectangular arrangement of 15 go stones

My three-year-old daughter Iris likes to play with the stones of my go set. Counting them is no longer a challenge for her. Nowadays we consider groupings. Having given her 15 stones, I let her make groups of three stones, then ask how many groups there are. At first, the idea of counting the groups, instead of

the stones, seems a bit confusing, but Iris soon caught on. Another task is to make three groups of five stones each, then counting the total number. The relationship between these two groupings---five groups of three and three groups of five---can be visualized by arranging the 15 stones in a three by five rectangular array (see Figure 1). In one case, the rows, in the other, the columns can be viewed as groups.

Playing with rectangles leads to multiplication and division. (But I do not bother Iris with those words.) If, as a father, you want to pick a number of go stones that allows your daughter to make many rectangular arrangements, then you need a number with many factors. Prime numbers are a particularly bad choice, because they only allow a degenerate rectangle. Prime numbers, which can be called `rectangle-free', are rather sparse. All this is well known to me.

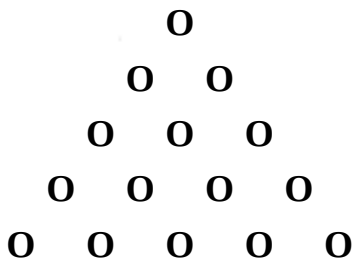

Figure 2: Triangular arrangement of 15 go stones

There are other appealing arrangements of go stones, such as equilateral triangles. The 15 stones can be arranged in a base-five triangle as shown in Figure 2. Unfortunately, each number allows only at most one such triangular arrangement, and most numbers are `triangle-free'. The triangular numbers are given by

$$1+2+...+n = n(n+1)/2$$

where n is the number of stones on the triangle's base. Such a number can be split into groups of consecutive sizes starting at size 1. Again, all well known to me.

The next thing that crossed my mind were trapezoidal arrangements. These offer more freedom than triangular numbers. Figure 3 shows two such arrangements with 15 stones. Some of the questions that intrigued me are: How many trapezoidal arrangements are there for a given number of stones? Does there exist, for each number k, a number that allows exactly k such arrangements? What is the smallest such number for a given k?

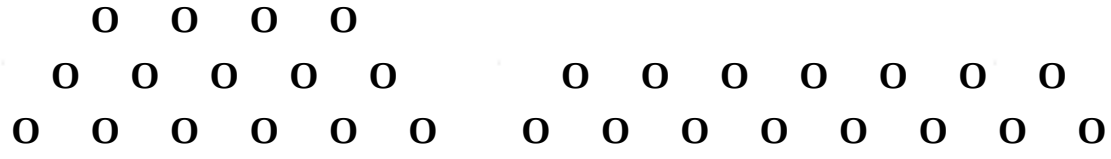

Figure 3: Two trapezoidal arrangements of 15 go stones

2. Definitions

A trapezoidal arrangement of n stones, in the sense that we study it here, consists of some rows of stones, where each next row contains one more stone than the row it succeeds. If the first row contains a stones and there are k rows, then the total number of stones is

$$a + (a+1) + ... + (a+k-1) = k(2a+k-1)/2$$

We introduce the notation $S.a.b$ for the sum of the numbers from a to and excluding b:

$$S.a.b = (\text{SUM } i: a<=i<b: i) = (b-a)(a+b-1)/2$$

The k-row trapezoid whose shortest row has a stones, contains a total of $S.a.(a+k)$ stones. We have the following summation formula for stacking `matched' trapezoids:

$$S.a.b + S.b.c = S.a.c$$

Substituting a:=1 and transferring $S.a.b$ to the other side, yields

$$S.b.c = S.1.c - S.1.b \qquad (1)$$

Note that $S.1.n$ are the triangular numbers. Therefore, each trapezoidal arrangement corresponds to the difference of two triangular numbers and vice versa.

Let $T.n$ be the number of trapezoidal arrangements of n for $1<=n$:

$$T.n = (\#\ a,b: 1<=a<b: n=S.a.b)$$

On account of (1), $T.n$ is also the number of ways to write n as the difference of two triangular numbers. Here is a table of $T.n$ for $1<=n<=20$ (in appendix A, we present some programs to compute $T.n$):

n:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
$T.n$:	1	1	2	1	2	2	2	1	3	2	2	2	2	2	4	1	2	3	2	2

Is there any order to be discovered behind $T.n$? Let $L.T.t$ be the least number that allows exactly t trapezoidal arrangements, that is,

$$L.T.t = (\text{MIN } n: 1<=n \text{ AND } T.n=t: n) \qquad (2)$$

Here is a table of $L.T.t$ for $1<=t<=10$:

t	1	2	3	4	5	6	7	8	9	10
$L.T.t$:	1	3	9	15	81	45	729	105	225	405

It is not self-evident that $L.T.t$ is well defined for all t. Can all n with given $T.n=t$ be simply characterized, especially for $t=1$ and $t=2$? The values n with $T.n=1$ can be called `trapezoid-free', because they only allow a degenerate trapezoidal arrangement in a single row.

3. Analysis

From the table above for $T.n$, one might conjecture that $T.n=1$ if and only if n is a power of two. The values for $L.T.t$, given in the table above, have factors three and five only. Is there an explanation? Note that these sequences do not appear in [Slo95].

3.1. Rectangular arrangements

First we consider these questions for rectangular arrangements. Define $R.n$ as the number of rectangular arrangements of n stones, modulo rotation:

$$R.n = (\#\ a,b:\ 1<=a<=b:\ n=ab)$$

Function L defined by (2) can be applied to R as well: $L.R.r$ is the least number that allows exactly r rectangular arrangements. Here is a table for $R.n$ with $1<=n<=20$:

n:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
$R.n$:	1	1	1	2	1	2	1	2	2	2	1	3	1	2	2	3	1	3	1	3

And a table for $L.R.r$ with $1<=r<=10$:

r	1	2	3	4	5	6	7	8	9	10
$L.R.t$:	1	4	12	24	36	60	192	120	180	240

Again, but this time more to my surprise, these sequences do not appear in [Slo95].

As already noted in the introduction, we have:

$R.n=1$ if and only if n is one or prime

To compute *R.n* in general, consider the prime factorization of *n*:

$$n = 2^{e_2} * 3^{e_3} * 5^{e_5} * \ldots \qquad (3)$$

with $0<=e_p$ for all primes *p*, and $0<e_p$ for only finitely many. Each divisor *d* of *n* is of the form

$$d = 2^{f_2} * 3^{f_3} * 5^{f_5} * \ldots$$

where $0<=f_p<=e_p$. Thus, the number *D.n* of divisors of *n* in (3) can be computed by

$$D.n = (e_2+1)(e_3+1)(e_5+1)\ldots \qquad (4)$$

Note that all divisors come in pairs *d* and *n*/*d*, except that *d*=*n*/*d* when *n* is a square. Note that *n* is a square if and only if each e_p is even, and hence if and only if *D.n* is odd. For *R.n* we are not interested in all divisors, only those at most Sqrt.*n*; thus, we have

$$R.n = \text{Ceiling.}(D.n / 2)$$

Hence, to compute *L.R.r* for a given *r*, we need to find the least *n* with *D.n*=2*r*-1 or *D.n*=2*r*, that is,

$$L.R.r = L.D.(2r\text{-}1) \text{ MIN } L.D.(2r)$$

where *L.D.d* is the least number with exactly *d* divisors. Sequence *L.D* is listed in [Slo95], but without additional information.

L.D.d exists for every *d*, because $n=2^{d\text{-}1}$, having exactly *d* divisors on account of (4), is an upper bound. *L.D.d* can be computed as follows. On account of (4), for given *d*, *L.D.d* is the least *n* satisfying (3) and

$$d = (e_2+1)(e_3+1)(e_5+1)\ldots \qquad (5)$$

Note that for $p<q$ and $e<=f$ we have

$$p^e q^f = p^e q^{f\text{-}e} q^e > p^e p^{f\text{-}e} q^e = p^f q^e$$

Thus, when computing *L.D.d*, we can restrict ourselves to *n* satisfying

$$e_2 >= e_3 >= e_5 >= \ldots \qquad (6)$$

Each of the---finitely many---factorizations of d satisfying (5) and (6) contributes exactly one candidate n. It is, in general, not the case that the sorted *prime* factorization of d yields the least n. For example, for d=8 there are three factorizations to consider:

d:	8	4*2	2*2*2
n:	2^7	2^3*3^1	$2^1*3^1*5^1$
	128	24	30

*L.D.*8=24 is obtained from the factorization 8=4*2.

3.2. Trapezoidal arrangements

Every trapezoidal arrangement of n stones can be associated with a rectangular arrangement of n stones. This is easy to see when the rows in the trapezoid are all shifted horizontally, say to the left, to introduce a right angle. Figure 4 shows the two trapezoids of Figure 3 in that format.

```
O O O O
O O O O O      O O O O O O O
O O O O O O    O O O O O O O O
```

Figure 4: Two right-angled trapezoidal arrangements of 15 go stones

In a trapezoid with an odd number of rows, say $2k+1$, the triangle sticking out over the bottom k rows can be rotated to fill the `missing' triangle on the top k rows. If the shortest row has a stones, then the resulting rectangle has height $2k+1$ and width $a+k$ (the average length of the rows in the trapezoid). In the example above, this transformation applies to the trapezoid on the left, and it yields a 3x5 rectangle (the rotated triangle consists of a single stone).

In a trapezoid with an even number of rows, say $2m$, the top m rows can be rotated to the right, matching the the slanted side of the bottom m rows. If the shortest row has a stones, then the resulting rectangle has height m and width $2a+2m-1$ (the length of the shortest plus the longest row). In the example above, this transformation applies to the trapezoid on the right, and it yields a 1x15 rectangle.

For both of these transformations, the resulting rectangle has an odd side: $2k+1$ in the first case, and $2(a+m-1)+1$ in the second. The resulting odd sides are unique, because if they were equal, the other sides would be equal as well, and hence $k=a+m+1$ and also $a+k=m$, which is impossible.

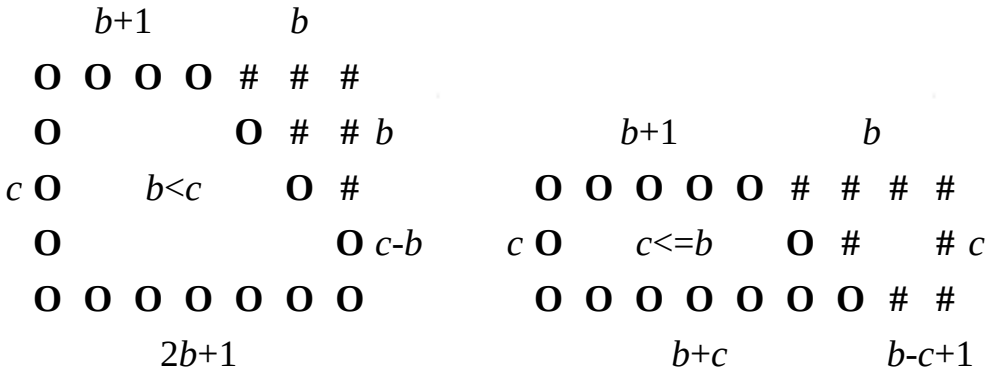

Figure 5: Cutting a cx $(2b+1)$ rectangle into two stackable trapezoids

Conversely, each rectangular arrangement of n stones with an odd side can be transformed into a trapezoidal arrangement of n stones. Assume the rectangle has odd width $2b+1$ and (arbitrary) height c (see Figure 5). The rectangle can be cut diagonally into two trapezoids, one with a *shortest* row of $b+1$ stones, one with a *longest* row of b stones. These two trapezoids have `matching' shortest and longest rows. When stacked together by rotating one on top of the other, the result is a single trapezoid. If $b<c$, the resulting trapezoids stands `sideways', with $2b+1$ (vertical) rows and a shortest row of $c-b$ stones. If $c<=b$, the resulting trapezoid has $2c$ rows and a shortest row of $b-c+1$ stones. In case $b=c-1$ or $b=c$, the resulting trapezoid is a triangle.

The transformations from trapezoid to rectangle and back are each other's inverse. Consequently, each *odd* divisor of n yields a unique trapezoidal arrangement of n stones, and we have

$$T.n = D'.n$$

where $D'.n$ is the number of odd divisors of n. When n is written as in (3), $D'.n$ can be computed by

$$D'.n = (e_3+1)(e_5+1)... \qquad (7)$$

that is, all factors two are ignored. From this we infer:

$T.n=1$ if and only if n is a power of two
$T.n=2$ if and only if n is an odd prime times a power of two

The ascending sequence of all n with $T.n=2$, that is, all products of an odd prime and a power of two, is not listed in [Slo95]. $L.D'.d$ exists for every d, because $n=3^{d-1}$, having exactly d odd divisors on account of (7), is an upper bound. $L.T.t$ can be determined in a way analogous to $L.D.d$. Since factors two in n do not contribute to the number of odd divisors, the *least* numbers n with exactly a given number of odd divisors have no factors two. This explains why in the table for $L.T.n$ shown earlier, only numbers with factors three and five appear (for a factor seven to appear, n must be larger than listed).

Conclusion

For positive integer *n*, we have defined the numbers *R.n* and *T.n* of, respectively, rectangular arrangements (modulo rotation) and trapezoidal arrangements of *n* identical objects. *R.n* trivially equals the number of divisors of *n* that are at most Sqrt.*n*. It turns out that *T.n* equals the number of *odd* divisors of *n*. Note that *T.n* also equals the number of ways that *n* can be written as the difference of two triangular numbers (considering zero a triangular number).

The numbers that allow exactly *one* trapezoidal arrangement, that is, numbers *n* with *T.n*=1, are the powers of two, a well-known sequence. The numbers *n* with *T.n*=2 are the products of an odd prime and a power of two. Concerning the difference of triangular numbers, Dickson [Dic66] refers only to [Bar10, Bar11]. However, Barbette's analysis is incorrect, claiming that *T.N* equals ``1, 2, or more than 2 ... according as *N* is a power of 2, an odd prime, or a composite number not a power of 2" [Dic66,p. 373].

For each positive integer *k*, there exists an *n* that allows exactly *k* such arrangements. The least such numbers *n* form another sequence, which is not monotonic.

Abbr.	Nr. in [EIS]	Description
S.1.n	A000217	Triangular numbers: *S.a.b*=(SUM *i*:*a*<=*i*<*b*:*i*)
T.n	A001227	# trapezoidal arrangements of *n*,

L.D.d	A005179	Least *n* with *D.n*=*d*
T.n=1	A000079	Unique trapezoidal arrangements, powers of 2
T.n=2	A038550+	Exactly 2 trapezoidal arrangements,
		odd prime times power of 2

Table 1: Sequences in this article with their absolute catalogue number in [EIS]

None of these sequences, except the powers of two, appears in [Slo95]. Afterwards, we did find *T.n* in [EIS]. Table 1 gives an overview of all sequences featured in this article. The leftmost column lists our notation, the middle column gives the absolute catalogue number in [EIS], + denoting newly

contributed sequences.

A. Programs

Exploiting that *S.a.b* is descending in *a* and ascending in *b*, an $O(n)$ program to determine *T.n* without multiplicative operators can be derived in the style of [Kal90]:

```
function T(const n: integer): integer
  { assumes 1<=n ; returns T.n }
; var t, x, y, s: integer
  { let U.x.y = (# a,b: x<=a<b AND y<=b: n=S.a.b),
    then T.n=U.1.2, and U.x.y=0 for x>n }
; begin
    t:=0 ; x:=1 ; y:=2 ; s:=1
    { inv: t+U.x.y=T.n and s=S.a.b }
  ; while x<=n do
      if s<n then begin s:=s+y ; y:=y+1 end
      else if s>n then begin s:=s-x ; x:=x+1 end
      else { s=n } begin t:=t+1 ; s:=s-x+y ; x:=x+1 ; y:=y
+1 end
  end { function T }
```

A slightly different linear program can be derived by rewriting *T.n* to

T.n = (# *a*,*k*: 1<=*a* AND 1<=*k*: *n*=*S.a.*(*a*+*k*))

in which *S.a.*(*a*+*k*)=*k*(2*a*+*k*-1)/2 is ascending in both *a* and *k*. This program can be further refined to an O(Sqrt.*n*) program to compute *T.n*:

```
function T(const n: integer): integer
  { assumes 1<=n ; returns T.n }
; var t, i, h: integer
  { let U.i = (# a,k: 1<=a AND 1<=k<i: n=S.a.(a+k)),
    then T.n=U.i if S.1.(i+1)>n }
; begin
    t:=0 ; i:=1 ; h:=1
    { inv: t=U.i and h=S.1.(i+1) }
  ; while h<=n do begin
      if (n-h) mod i = 0 then t:=t+1
    ; i:= i+1 ; h:=h+i
    end { while }
  end { function T }
```

Abstract: We introduce a generalization of the Connell Sequence which relies on two parameters**:** the modulus *m* and the successive row length difference *r*. We show its relationship with polygonal numbers, examine its limiting behavior, and find an expression for the general term.

1. Introduction

In 1959 Ian Connell [1] introduced to the public a curious sequence which now bears his name

1, 2, 4, 5, 7, 9, 10, 12, 14, 16, 17, **...**

(A001614 in the *On-Line Encyclopedia of Integer Sequences*), in which the first odd number is followed by the next two even numbers, which in turn are followed by the next three odd numbers, and so on.

Lakhtakia and Pickover [3] arranged this sequence as a concatenation of finite subsequences,

Subsequence Number :	Subsequence :
1	1
2	2, 4
3	5, 7, 9

4	10, 12, 14, 16
...	...

where the nth subsequence contains n elements, the last of which is n^2. So if we let $c(n)$ denote the nth element of the Connell sequence then

$$c(T_n) = n^2 , \qquad (1)$$

where $T_n = n (n + 1)/ 2$ denotes the nth triangular number. Lakhtakia and Pickover [3] used (1) to show that

$$\lim_n c(n) / n = 2 , \qquad (2)$$

thus explaining the limiting behavior of the Connell sequence. The same authors remarked that (2) could have been obtained directly from the formula for $c(n)$ given by Connell [1]

$$c(n) = 2n - \text{Floor}((1 + \text{Sqrt}(8n - 7)) / 2) . \qquad (3)$$

Stevens [4] defined a generalized Connell k-sequence C_k for integers $k >= 2$ (whereby the classical Connell sequence becomes the special case C_2). In this paper we further generalize the Connell sequence by affixing another parameter onto Stevens's sequence C_k.

2.Generalized Connell Sequence with Parameters

For fixed integers $m >= 2$ and $r >= 1$ we construct a sequence as follows**:** take the first integer which is congruent to 1 (mod m) (that being 1 itself), followed by the next $1 + r$ integers which are congruent to 2 (mod m), followed by the next $1 + 2r$ integers which are congruent to 3 (mod m), and so on. If $m = 2$ and $r = 1$ (the smallest possible cases) we have the Connell sequence. Here is the formal definition.

Definition 1: Let $m >= 2$ and $r >= 1$ be integers. We denote by $C_{m,r}(n)$ the nth term of the generalized Connell sequence with parameters m and r, or, simply, the **Connell (*m* , *r*)-*sequence*.** The sequence is defined as follows:

1. The sequence is formed by concatenating subsequences $S_1, S_2, \ldots$, each of finite length.

2. The subsequence S_1 consists of the element 1.

3. If the nth subsequence S_n ends with the element e, then the $(n+1)$th subsequence S_{n+1} begins with the element $e+1$.

4. If S_n consists of t elements, then S_{n+1} consists of $t + r$ elements.

5. Each subsequence is nondecreasing, and the difference between two consecutive elements in the same subsequence is m.

The sequence C_k of Stevens [4] is the sequence $C_{k,1}$. When $(m , r) = (3 , 2)$ we obtain $C_{3, 2}$ **:**

n	S_n
1	1
2	2, 5, 8
3	9, 12, 15, 18, 21
4	22, 25, 28, 31, 34, 37, 40
...	...

The final elements 1, 8, 21, 40, **...** in the subsequences appear to be the octagonal numbers, $E_n = n(3n-2)$. The nth subsequence S_n contains exactly $2n - 1$ elements, and from the identity $1 + 3 + \ldots + (2n-1) = n^2$ we obtain

$$C_{3,2}(n^2) = E_n .$$

Just as the Connell sequence relates triangular numbers to squares (see (1)), the sequence $C_{3,2}$ relates squares to octagonal numbers. Triangular numbers, squares, and octagonal numbers are all examples of *polygonal numbers.*

3. Relationships with Polygonal Numbers

Definition 2: For integers $k >= 3$, the nth k-gonal number is

$$P_k(n) = n ((k -2) n - k + 4) / 2 \ .$$

We shall demonstrate the relationship between generalized Connell sequences and polygonal numbers. Consider the sequence $C_{m,r}$. By induction (see conditions 2 and 4 in Definition 1), S_n contains exactly $(n - 1) r + 1$ elements. Therefore to reach the end of nth subsequence S_n , we must count exactly

$$| S_1| + | S_2| + \ ... \ + | S_n | = P_{r+2}(n)$$

elements of the sequence $C_{m,r}$. Hence the last element of S_n is $C_{m,r} (P_{r+2}(n))$. Thus S_{n+1} begins (see condition 3 of Definition 1) with the element $C_{m,r} (P_{r+2}(n)) + 1$, and, since $| S_{n+1} | = nr + 1$, it ends (see condition 5 of Definition 1) with
the element $C_{m,r} (P_{r+2}(n)) + 1 + m (nr + 1)$. But this last element is also expressible as $C_{m,r} (P_{r+2} (n + 1))$. Therefore, assuming the induction hypothesis $C_{m,r} (P_{r+2}(n)) = P_{mr+2}(n)$, we obtain

$$C_{m,r} (P_{r+2}(n + 1)) = P_{mr+2}(n) + 1 + m (nr + 1) = P_{mr+2}(n + 1) ,$$

and hence by induction we have for all positive integers n,

$$C_{m,r} (P_{r+2}(n)) = P_{mr+2}(n) . \qquad (4)$$

(1) is the special case of (4) when $(m , r) = (2 , 1)$. As we remarked in Section 2, $C_{3,2}(P_4(n)) = P_8 (n)$. Another example is given by $C_{3,1}$ (A033292) **:**

n	S_n
1	1
2	2, 5
3	6, 9, 12
4	13, 16, 19, 22
...	...

Here the pentagonal numbers $P_5(n) = n(3n - 1)/2$ at the end of each subsequence.

It is interesting to note that, since all elements of S_n are congruent to $n \pmod m$, we obtain the following property of polygonal numbers: $P_{mr+2}(n)$ is congruent to $n \pmod m$.

4. Limiting Behavior

We will determine the behavior of $C_{m,r}(n)/n$ as n goes to infinity, following Lakhtakia and Pickover [3], by computing $\lim_n C_{m,r}(n)/n$ from (4). Let n be a positive integer. There is a positive j, and a fixed i such that $1 <= i <= 1 + rj$, for which $n = P_{r+2}(j) + i$. Thus $C_{m,r}(n)$ belongs to the subsequence S_{j+1}. As $C_{m,r}(P_{r+2}(j))$ is the last element of S_j, we have from Definition 1 and (4)

$$\begin{aligned} C_{m,r}(n) &= C_{m,r}(P_{r+2}(j) + i) \\ &= C_{m,r}(P_{r+2}(j)) + 1 + (i - 1)m \\ &= P_{mr+2}(j) + 1 + (i - 1)m. \end{aligned}$$

Thus, since $1 <= i <= 1 + rj$ and $n = P_{r+2}(j) + i$, we have $A <= C_{m,r}(n)/n <= B$, where

$$A = (P_{mr+2}(j) + 1)/(P_{r+2}(j) + 1 + rj),$$

$$B = (P_{mr+2}(j) + 1 + jmr)/(P_{r+2}(j) + 1).$$

Recalling Definition 2, it is a simple matter to verify that A and B both converge to the limit m as j tends toward infinity. Therefore

$$\lim_n C_{m,r}(n)/n = m. \qquad (5)$$

5. A Direct Formula

To find a formula for $C_{m,r}(n)$ we modify Korsak's [2] proof of (3). Define the sequence T by

$$T(n) = mn - C_{m,r}(n).$$

We assume $n > 1$ and write $n = P_{r+2}(j) + i$ exactly as in Section 4. Then after some algebra we find that $T(n) = (j + 1)(m - 1)$, so $j + 1 = T(n)/(m - 1)$. Since $n >= P_{r+2}(j) + 1$,

$$rj^2 - (r - 2)j - (2n - 2) <= 0,$$

a quadratic inequality in j which implies

$$j + 1 <= (3r - 2 + \text{Sqrt}(8r (n -1) + (r - 2)^2)) / 2k ,$$

and hence

$$j + 1 = \text{Floor}((3r - 2 + \text{Sqrt}(8r (n -1) + (r - 2)^2)) / 2k) .$$

Thus

$$T(n) = (m - 1) \text{Floor}((3r - 2 + \text{Sqrt}(8r (n -1) + (r - 2)^2)) / 2k) ,$$

and so

$$C_{m,r}(n) = nm - (m - 1) \text{Floor}((3r - 2 + \text{Sqrt}(8r (n -1) + (r - 2)^2)) / 2k) . \quad (6)$$

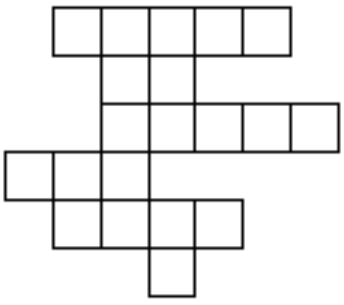
Counting Horizontally Convex Polyominoes

Dean Hickerson
Dept. of Mathematics
University of California, Davis
Email address: dean@math.ucdavis.edu

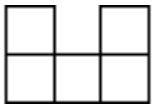
Abstract: We present a new proof that the number, a(n), of horizontally convex n-ominoes satisfies the recurrence a(n) = 5 a(n-1) - 7 a(n-2) + 4 a(n-3).

0. Introduction

A finite union of closed unit squares whose vertices have integer coordinates is called a polyomino if its interior is connected. A polyomino of area n is called an n-omino. We will consider two polyominoes to be the same if one is a translate of the other. A polyomino P is horizontally convex if each horizontal line meets P in a single line segment, or not at all. For example, the first polyomino below is horizontally convex; the second one is not.



Horizontally convex



Not horizontally convex

Let a(n) be the number of horizontally convex n-ominoes. The table below shows the values of a(n) for n up to 12; see sequence A001169 in [EIS] for more values:

n	1	2	3	4	5	6	7	8	9	10	11	12
a(n)	1	2	6	19	61	196	629	2017	6466	20727	66441	212980

Remarkably, a(n) satisfies a third order linear recurrence.

Theorem: For n>=5,

$$a(n) = 5\,a(n-1) - 7\,a(n-2) + 4\,a(n-3). \tag{0.0}$$

From this it can be shown that

$$a(n) \sim u\,v^n, \tag{0.1}$$

where

$$v = 3.2055694304... \tag{0.2}$$

is the unique real root of

$$v^3 - 5\,v^2 + 7\,v - 4 = 0, \tag{0.3}$$

and

$$u = \frac{163 - 129\,v + 41\,v^2}{944} = 0.1809155018... \tag{0.4}$$

The recurrence (0.0) was apparently first proved by Pólya in 1938, although his proof does not seem to have been published. (In [P] he says "The proofs of the results stated will be given in a continuation of this paper.", but no such continuation seems to exist.)

All of the published proofs are "2-dimensional" in the following sense: Instead of working with functions of one variable, like a(n), they introduce the function a(r,n), which is the number of

horizontally convex n-ominoes with exactly r squares in the top row. Obviously

$$a(n) = \sum_{r=1}^{n} a(r,n) \quad \text{for} \quad n>=1. \tag{0.5}$$

Also,

$$a(r,n) = \sum_{s=1}^{n-r} (r+s-1)\, a(s,n-r) \quad \text{for} \quad 1 <= r < n, \tag{0.6}$$

since we may add a row of r squares to the top of a polyomino counted by a(s,n-r) in exactly r+s-1 ways.

It is not obvious that these equations imply a recurrence involving only a(n). But it can be shown that they do, either directly as in [K0] or by means of generating functions as in [K1], [S0, pp. 111-113], [S1, pp. 256-259], and [T, pp. 7-8].

In contrast, the proof given here is 1-dimensional: We introduce 4 new functions of n, each of which counts certain restricted types of horizontally convex n-ominoes. We find linear relations among these functions and combine them to obtain the recurrence.

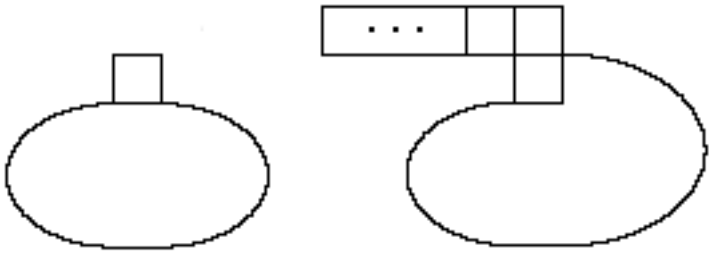
1. Proof of the Theorem

Definition: If n>=1, then:

b(n) is the number of horizontally convex n-ominoes in which the top row has exactly one square;

c(n) is the number of horizontally convex n-ominoes in which the top row has at least two squares and the rightmost square in the top row is directly above the leftmost square in the second row.

The figures below suggest the approximate shapes of polyominoes counted by b(n) and c(n).



Counted by b(n) Counted by c(n)

Lemma 0: For n>=2,

$$a(n) = a(n-1) + b(n) + c(n). \quad (1.0)$$

Proof: If we add a square to the right end of the top row of a horizontally convex (n-1)-omino, we obtain a horizontally convex n-omino in which the top row has at least two squares and the rightmost square in the top row is not above the leftmost square in the second row; such n-ominoes are counted by a(n) - b(n) - c(n). Conversely, each such n-omino is obtained from a unique horizontally convex (n-1)-omino by this process. Hence a(n) - b(n) - c(n) = a(n-1). QED

Lemma 1: For n>=3,

$$c(n) = c(n-1) + a(n-2). \quad (1.1)$$

Proof: Let P be a polyomino counted by c(n). If P has at least three squares in the top row, we can delete the leftmost square to obtain a polyomino counted by c(n-1). If P has exactly two squares in the top row, we can delete both of them to obtain a horizontally convex (n-2)-omino. These processes are reversible, so we obtain (1.1). QED

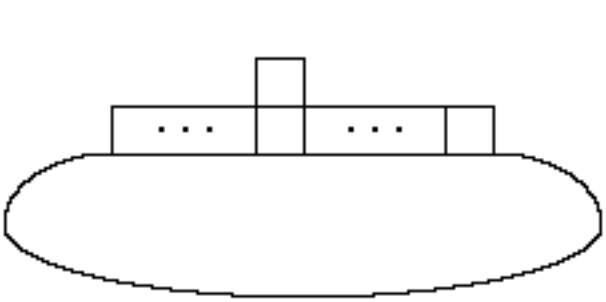
To obtain an equation for b(n), we introduce two more functions:

Definition: If n>=1, then:

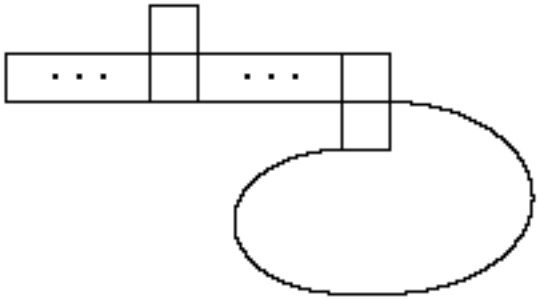
d(n) is the number of horizontally convex n-ominoes in which the top row has exactly one square and this square is not above the rightmost square in the second row;

e(n) is the number of horizontally convex n-ominoes in which the top row has exactly one square, this square is not above the rightmost square in the second row, and the rightmost square in the second row is above the leftmost square in the third row.

The figures below suggest the approximate shapes of polyominoes counted by d(n) and e(n).



Counted by d(n)



Counted by e(n)

Lemma 2: For n>=2,

$$b(n) = a(n-1) + d(n). \tag{1.2}$$

Proof: b(n) - d(n) is the number of horizontally convex n-ominoes in which the top row has exactly one square, which is above the rightmost square in the second row. Deleting the top square from such a polyomino gives a horizontally convex (n-1)-omino. Conversely, adding a square above the rightmost square in the top row of a horizontally convex (n-1)-omino gives a polyomino counted by b(n) - d(n). QED

Lemma 3: For n>=3,

$$d(n) = b(n-1) + e(n). \tag{1.3}$$

Proof: d(n) - e(n) is the number of horizontally convex n-ominoes in which the top row has exactly one square, this square is not above the rightmost square in the second row, and the rightmost square in the second row is not above the leftmost square in the third row. (Note that this includes some n-ominoes in which there is no third row.) If we delete the rightmost square in the second row of such a polyomino, we obtain a polyomino counted by b(n-1). Conversely, adding a square to the right end of the second row of a polyomino counted by b(n-1) gives one counted by d(n) - e(n). (The condition n>=3 is needed to ensure that a polyomino counted by b(n-1) has at least two rows.) QED

Combining Lemmas 2 and 3 gives

$$b(n) = b(n-1) + a(n-1) + e(n) \tag{1.4}$$

for n>=3.

Lemma 4: For n>=2,

$$e(n) = e(n-1) + c(n-1). \tag{1.5}$$

Proof: Let P be a polyomino counted by e(n). If the top square of P is directly above the leftmost square in the second row of P, then deleting the top square gives a polyomino counted by c(n-1). Otherwise, deleting the leftmost square in the second row gives a polyomino counted by e(n-1). These operations are reversible, so (1.5) follows. QED

It is now a straightforward matter to combine equations (1.0), (1.1), (1.4), and (1.5) to obtain the Theorem: By (1.0),

$$a(n) - a(n-1) = b(n) + c(n) \quad \text{for } n>=2.$$

Hence, for n>=3,

$$\begin{aligned} a(n) - 2\,a(n-1) + a(n-2) &= (b(n) + c(n)) - (b(n-1) + c(n-1)) \\ &= (b(n) - b(n-1)) + (c(n) - c(n-1)) \\ &= a(n-1) + e(n) + a(n-2), \end{aligned}$$

by (1.1) and (1.4). Thus

$$a(n) - 3\,a(n-1) = e(n) \quad \text{for } n>=3.$$

So, for n>=4,

$$\begin{aligned} a(n) - 4\,a(n-1) + 3\,a(n-2) &= e(n) - e(n-1) \\ &= c(n-1), \end{aligned}$$

by (1.5). Finally, for n>=5,

$$\begin{aligned} a(n) - 5\,a(n-1) + 7\,a(n-2) - 3\,a(n-3) &= c(n-1) - c(n-2) \\ &= a(n-3), \end{aligned}$$

by (1.1). This implies the Theorem.

2. Concluding remarks

The functions b(n), c(n), d(n), and e(n) all satisfy the same recurrence as does a(n) (for sufficiently large n), since each can be expressed as a linear combination of a(n), a(n-1), a(n-2): In fact it is easy to show that

$$b(n) = 3\,a(n-1) - 4\,a(n-2) \quad \text{for} \quad n>=4; \tag{2.0}$$

$$c(n) = a(n) - 4\,a(n-1) + 4\,a(n-2) \quad \text{for} \quad n>=4; \tag{2.1}$$

$$d(n) = 2\,a(n-1) - 4\,a(n-2) \quad \text{for} \quad n>=4; \tag{2.2}$$

$$e(n) = a(n) - 3\,a(n-1) \quad \text{for} \quad n>=3. \tag{2.3}$$

Consequently, each satisfies an asymptotic formula like (0.1), with the same value of v but different values of u.

A short table of these functions is given below. More values are given in [EIS]; see A001169 for a(n), A049219 for b(n), A049220 for c(n), A049221 for d(n), and A049222 for e(n).

n	a(n)	b(n)	c(n)	d(n)	e(n)
1	1	1	0	1	0
2	2	1	0	0	0
3	6	3	1	1	0
4	19	10	3	4	1

The Fifth Taxicab Number is 48988659276962496

David W. Wilson
263 E. Ricker Road
Loudon, NH 03301
Email address: wilson@ctron.com

Abstract: The *n*th taxicab number is the least number which can be expressed as a sum of two positive cubes in *n* distinct ways, up to order of summands. A brief history of taxicab numbers is given, along with a description of the computer search used by the author to find the 5th taxicab number, 48988659276962496. Additional results from the search are summarized.

1. Introduction

The *n*th *taxicab number* is the least integer which can be expressed as a sum of two positive cubes in (at least) *n* distinct ways, up to order of summands. In [HW54], there is a constructive proof that for any $n >= 1$, there exist numbers which can be expressed in exactly *n* ways as a sum of two cubes (hereafter, we will call such numbers *n-way sums*). This guarantees the existence of a least *n*-way sum (that is, the *n*th taxicab number) for $n >= 1$, however, the construction given in [HW54] is of no help in finding the least *n*-way sum.

The first taxicab number is trivially

$$\begin{aligned} Ta(1) &= 2 \\ &= 1^3 + 1^3. \end{aligned}$$

The second taxicab number was first published by Frénicle de Bessy in 1657:

$$\begin{aligned} Ta(2) &= 1729 \\ &= 1^3 + 12^3 \\ &= 9^3 + 10^3. \end{aligned}$$

This particular number was immortalized by the following well-known incident involving G. H. Hardy and Srinivasa Ramanujan:

> I [G. H. Hardy] remember once going to see him [Ramanujan] when he was lying ill at Putney. I had ridden in taxi-cab No. 1729, and remarked that the number (7.13.19) seemed to be rather a dull one, and that I hoped it was not an unfavourable omen.
>
> "No," he replied, "it is a very interesting number; it is the smallest number expressible as the sum of two [positive] cubes in two different ways." [R27, p. xxxv]

The appelation *taxicab number*, as well as the name *Hardy-Ramanujan number* for the number 1729, arose from this incident.

Subsequent taxicab numbers were discovered by computer search. In 1957, Leech obtained

$$\begin{aligned} \mathrm{Ta}(3) &= 87539319 \\ &= 167^3 + 436^3 \\ &= 228^3 + 423^3 \\ &= 255^3 + 414^3, \end{aligned}$$

and in 1991 Rosenstiel, Dardis, and Rosenstiel [RDR91] found

$$\begin{aligned} \mathrm{Ta}(4) &= 6963472309248 \\ &= 2421^3 + 19083^3 \\ &= 5436^3 + 18948^3 \\ &= 10200^3 + 18072^3 \\ &= 13322^3 + 16630^3. \end{aligned}$$

This paper announces the author's discovery, in November 1997, of the fifth taxicab number

$$\begin{aligned} \mathrm{Ta}(5) &= 48988659276962496 \\ &= 38787^3 + 365757^3 \\ &= 107839^3 + 362753^3 \\ &= 205292^3 + 342952^3 \\ &= 221424^3 + 336588^3 \\ &= 231518^3 + 331954^3. \end{aligned}$$

The taxicab numbers form sequence A011541 in [OEIS].

2. Background

An *n-way sum* is an integer *s* which can be expressed as the sum of two cubes in exactly *n* different ways, i.e:

$$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = \ldots = a_n^3 + b_n^3.$$

where $a_i <= b_i$ for $1 < i < n$. Without loss of generality, we assume $a_1 < a_2 < \ldots < a_n$.

A *primitive n-way sum* is an *n*-way sum for which the a_i and b_i taken together have no common factor. If an *n*-way sum is non-primitive, it can be divided by $\gcd(a_1, b_1, a_2, b_2, \ldots, a_n, b_n)^3$, reducing it to a primitive sum. For this reason, only primitive sums are considered interesting.

There are two techniques which are useful for constructing new primitive *n*-way sums from known ones. I call these techniques *combination* and *magnification*.

The combination technique

The combination technique is used to combine two primitive *n*-way sums into a primitive (*n*+1)-way sum.

First, a preliminary definition:

Definition: Let *n* be a positive integer, and let *c* be the least positive integer such that there exists integer *d* with $n = cd^3$. *c* is called the *cubefree part* of *n*. The cubefree part of *n* is what is left after all nontrivial cubes have been divided out of *n*.

In order to apply the combination technique to two *n*-way sums, both sums must have the same cubefree part. Let *s* and *s´* be *n*-way sums with cubefree part *c*. Then we have

$$s = cd^3 = a_1^3 + b_1^3 = a_2^3 + b_2^3 = \ldots = a_n^3 + b_n^3$$
$$s' = cd'^3 = a_1'^3 + b_1'^3 = a_2'^3 + b_2'^3 = \ldots = a_n'^3 + b_n'^3.$$

These can be combined to give

$$\begin{aligned} s'' &= c(dd')^3 \\ &= sd'^3 = (a_1d')^3 + (b_1d')^3 = (a_2d')^3 + (b_2d')^3 = \ldots = (a_nd')^3 + (b_nd')^3 \\ &= s'd^3 = (a_1'd)^3 + (b_1'd)^3 = (a_2'd)^3 + (b_2'd)^3 = \ldots = (a_n'd)^3 + (b_n'd)^3 \end{aligned}$$

This gives 2*n* representations of *s*´´ as a sum of two cubes. At least *n* of these representations must be distinct, since they are multiples of the *n* distinct representations of *s*. If exactly *n* of the representations are distinct, we can then divide out common factors to arrive at the same primitive *n*-way sum for *s* and *s*´, whence *s* = *s*´, contrary to assumption. We must conclude that at least *n* + 1 of these representations are distinct, and that *s*´´ is at least an (*n*+1)-way sum.

As an example, consider the two primitive 3-way sums:

$$327763000 = 300^3 + 670^3 = 339^3 + 661^3 = 510^3 + 580^3$$
$$26059452841 = 417^3 + 2962^3 = 1290^3 + 2881^3 = 2193^3 + 2494^3$$

327763000 and 26059452841 each have the cubefree part 327763, which means that these sums can be combined. We obtain

$$26059452841000 = 327763000 \cdot 43^3 = (300 \cdot 43)^3 + (670 \cdot 43)^3 = (339 \cdot 43)^3 + (661 \cdot 43)^3 = (510 \cdot 43)^3 + (580 \cdot 43)^3$$
$$= 26059452841 \cdot 10^3 = (417 \cdot 10)^3 + (2962 \cdot 10)^3 = (1290 \cdot 10)^3 + (2881 \cdot 10)^3 = (2193 \cdot 10)^3 + (2494 \cdot 10)^3.$$

Out of six representations, four are distinct, and we obtain the 4-way sum:

$$26059452841000 = 4170^3 + 29620^3 = 12900^3 + 28810^3 = 14577^3 + 28423^3 = 21930^3 + 24940^3.$$

The magnification technique

The magnification technique is used to obtain a primitive (*n*+1)-way sum from a primitive *n*-way sum.

The idea is simple. If we have a primitive *n*-way sum

$$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = \ldots = a_n^3 + b_n^3$$

we know that every cubic multiple of that sum will also be a (non-primitive) *n*-way sum:

$$sd^3 = (a_1 d)^3 + (b_1 d)^3 = (a_2 d)^3 + (b_2 d)^3 = \ldots = (a_n d)^3 + (b_n d)^3.$$

For some fortunate choice of multiple d^3, we might hope for the serendipitous appearance of a new representation:

$$sd^3 = (a_1d)^3 + (b_1d)^3 = (a_2d)^3 + (b_2d)^3 = \ldots = (a_nd)^3 + (b_nd)^3 = a'^3 + b'^3.$$

It turns out that often enough this hope is justified. For example, starting again with the 3-way sum

$$327763000 = 300^3 + 670^3 = 339^3 + 661^3 = 510^3 + 580^3,$$

we multiply 327763000 successively by $d^3 = 1^3, 2^3, 3^3$, etc, each time checking for a new representation. Finally, at $d^3 = 43^3$, an unexpected(?) solution arises:

$$327763000\cdot 43^3 = (300\cdot 43)^3 + (670\cdot 43)^3 = (339\cdot 43)^3 + (661\cdot 43)^3 = (510\cdot 43)^3 + (580\cdot 43)^3 = 4170^3 + 29620^3,$$

and we have found the 4-way sum 26059452841000.

From a computational standpoint, exploiting the magnification technique to find *n*-way sums is essentially a search procedure, whose feasibility relies heavily on the speedy detection of the extra representation, which is to say, the efficient complete solution of $s = a^3 + b^3$ for *a* and *b* given *s*. When implementing the magnification technique, I found that even a Bresenham search was not practical for the large *s* with which I was concerned. Fortunately, I was able to construct a more efficient algorithm to solve $s = a^3 + b^3$, using some known favorable properties of *s*.

First, we note that *s* is of the form

$$s = (\text{cube})\cdot(n\text{-way sum})$$

We know the cube factor beforehand. The *n*-way sum factor by definition has *n* distinct representations as $a^3 + b^3 = (a + b)(a^2 - ab + b^2)$, that is, *n* distinct representations as a product of two integers. From this observation we conclude that *n*-way sums should be highly factorable (for example, the 3-way sum $327763000 = 2^3\cdot 5^3\cdot 31\cdot 97\cdot 109$). This means that *s* should be highly factorable, and in practice even large *s* can be factored quickly using trial division.

Given that *s* is highly factorable, the following is an efficient method for solving $s = a^3 + b^3$:

- Use trial division to obtain the prime factorization of *s*.
- Use the prime factorization to build a list of all factors of *s*.
- From this factor list, compose a list of all pairs (p, q) with $p <= q$ and $pq = s$.
- For each pair (p, q) in the pair list, solve $p = a + b$ and $q = a^2 - ab + b^2$ for *a* and *b*.
- If *a* and *b* are both positive integers, then (a, b) solves $s = pq = (a + b)(a^2 - ab + b^2) = a^3 + b^3$.

It is not hard to show that this method generates all solutions to $s = a^3 + b^3$.

3. The Search for Ta(5)

The search for the fifth taxicab number arose from an attempt to extend sequence A003826 of [OEIS], the sequence of primitive 4-way sums. Prior to my work, A003826 contained four entries, first published in [RDR91]. In order to extend this sequence, I wrote a computer program to search for *n*-way sums. The program was written in the C programming language with 64-bit arithmetic, and ran on a Sun Sparc 5 workstation.

The approach was straightforward: Generate a sequence S of all triples of the form $(a, b, s = a^3 + b^3)$ with $a <= b$, sorted on s, and detect and record runs of contiguous triples in S having equal s values. A run of n contiguous triples (a_1, b_1, s), (a_2, b_2, s), ..., (a_n, b_n, s) in S indicates that s is the n-way sum

$$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = \ldots = a_n^3 + b_n^3.$$

The run detection part is relatively easy, so the problem really devolves to the efficient generation of S. My algorithm was:

1. Initialize priority queue Q to contain all triples of the form $(a = k, b = k, s = 2k^3)$ with $1 <= s < 2^{64}$ (this avoids 64-bit overflow of s, and translates to $1 <= k < 2^{21} = 2097152$). Q assigns higher priority to triples with smaller values of s.
2. Obtain triple (a, b, s) with smallest s value (high priority element) from Q.
3. Pass triple (a, b, s) to the run detector.
4. Let $(a, b, s) := (a, b + 1, a^3 + (b + 1)^3)$.
5. Add (a, b, s) back into Q.
6. Go to step 2.

The run detector, for its part, detects and prints runs of $n >= 3$ contiguous triples with equal s values passed to it, which correspond to n-way sums. The run detector need store no more than five triples at any time.

The only technical concern with this algorithm is that s might overflow in step 4. However, I determined beforehand that I would manually interrupt the program long before this could happen, which is also why there is no termination condition on the main loop.

I wrote several versions of this program. In the first, Q was implemented as a linked list. This program verified Leech's 1957 value for Ta(3) in less than a second. After running a month, it also verified the four least primitive 4-way sums given in [RDR91], but was unable to find any new 4-way sums.

Some time later, I applied the combination technique discussed in section 2 to the n-way sums that had

been computed by this first version of this program. This led me to discover the primitive 5-way sum

$$\begin{aligned} t &= 490593422681271000 \\ &= 48369^3 + 788631^3 \\ &= 233775^3 + 781785^3 \\ &= 285120^3 + 776070^3 \\ &= 543145^3 + 691295^3 \\ &= 579240^3 + 666630^3 \end{aligned}$$

Since Ta(5) <= $t < 2^{64}$, this discovery showed that Ta(5) could in principle be found using the same basic 64-bit algorithm with which I had attacked A003826.

However, a quick estimate convinced me that verifying Ta(5) = t using the algorithm as it then stood would take several years. This prompted me to make several improvements to the algorithm. Most notably, Q was reimplemented as a heap, and a and b replaced by pointers into an array of precomputed cubes. These and other optimizations speeded up the program considerably, reducing a month-long computation via the first version to less than one day. I estimated that Ta(5) = t could now be verified in approximately 8 months.

I began running the new program in earnest in October 1997. After I had run the program for about a month, I applied the magnification technique described in section 2 to its results. This led to the discovery of the yet smaller 5-way sum 48988659276962496. On November 17, the program verified that this 5-way sum was indeed Ta(5).

I later found that many of the basic search techniques I used to find Ta(5) had been used earlier by Bernstein on a variety of similar Diophantine problems. [B98] details Bernstein's techniques and discoveries. Though Bernstein did eventually apply his methods to sums of cubes, his independent discovery of Ta(5) = 48988659276962496 came a few months after mine.

4. Search Results

The main product of my search for the Ta(5) was a exhaustive list of all 3, 4, and 5-way sums of two cubes less than $5 \cdot 10^{16}$ (2-way sums were too numerous to record). The following table summarizes the counts of various types of n-way sums found in the search:

Table 1: Counts of *n*-way sums of two cubes

$$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = \ldots = a_n^3 + b_n^3$$

$$s <= 5 \cdot 10^{16}$$

Type of sum	$n = 3$	$n = 4$	$n = 5$
All **No constraints**	16159	143	1
Primitive **gcd(a_1, b_1, a_2, b_2, ..., a_n, b_n) = 1**	1630	35	1
Coprime Pair **gcd(a_i, b_i) = 1 for some i**	892	9	1
All Pairs Coprime **gcd(a_i, b_i) = 1 for all i**	81	0	0
Prime Occurrence **a_i or b_i prime for some i**	419	5	1
Prime Pair **a_i, b_i both prime for some i**	27	1	1

In the following tables, primes are in red, and nonprime members of a coprime pair are in green.

The search program found the 1630 least primitive 3-way sums of two cubes, too many to include in this article. Instead, I have composed several small tables of selected 3-way sums.

81 3-way sums of two cubes in which all pairs are coprime were found. Table 2 list the first 30 of these. Sums with all pairs coprime are hard to find, as they cannot be generated using the combination or magnification techniques described in Section 2, and their discovery lends some credence to the search algorithm. The ***s*** column of this table forms sequence A023050 of [OEIS].

Table 2: 30 least 3-way sums of two cubes with all pairs coprime

$$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = a_3^3 + b_3^3$$

$$\gcd(a_1, b_1) = \gcd(a_2, b_2) = \gcd(a_3, b_3) = 1$$

27 3-way sums of two cubes were found in which a prime pair occurs. Table 3 lists them all. Immediately it appears that a 3-way sum with a prime pair will not admit another coprime pair. I am hesitant to conjecture this, though, since the analogous assertion for 2-way sums is not true (e.g, $6058655748 = 61^3 + 1823^3 = 1049^3 + 1699^3$ [K99] and $6507811154 = 31^3 + 1867^3 = 397^3 + 1861^3$ [H99]).

Table 3: 27 least 3-way sums of two cubes involving a prime pair
$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = a_3^3 + b_3^3$
a_i and b_i both prime for some i

35 primitive 4-way sums were found. This corroborates and greatly extends the list of four originally included in [RDR91]. The ***s*** column of Table 5 forms sequence A003826 of [OEIS]. As can be seen, only nine of the 4-way sums (nos. 6, 7, 17, 19, 22, 25, 27, 30, and 35) involve a coprime pair, only five (nos. 7, 17, 22, 25, 30) include a prime, and just one (no. 25) involves a prime pair. Note also that no. 25 bolsters the theory that prime pairs in 3-way sums do not admit other coprime pairs.

Table 5: 35 least primitive 4-way sums of two cubes
$s = a_1^3 + b_1^3 = a_2^3 + b_2^3 = a_3^3 + b_3^3 = a_4^3 + b_4^3$
$\gcd(a_1, b_1, a_2, b_2, a_3, b_3, a_4, b_4) = 1$

34	41799396718910376	120876	342090	150376	337370	176544	331098	206703	320649
35	43819222861788696	132598	346184	155591	342145	181032	335862	202470	328716

The only 5-way sum discovered directly by the search was, of course

$$\begin{aligned} Ta(5) &= 48988659276962496 \\ &= 38787^3 + 365757^3 \\ &= 107839^3 + 362753^3 \\ &= 205292^3 + 342952^3 \\ &= 221424^3 + 336588^3 \\ &= 231518^3 + 331954^3. \end{aligned}$$

here colored to indicate primality. Surprisingly, this 5-way sum includes a prime pair, again confirming that a prime pair in a 3-way sum admits no other coprime pair.

On the lighter side, a single primitive 3-way sum was found containing only even digits, and one containing only odd digits:

$$\begin{aligned} 24248680282008000 &= 78300^3 + 287520^3 \\ &= 208059^3 + 247941^3 \\ &= 227520^3 + 231900^3 \end{aligned}$$

$$\begin{aligned} 9539173995131151 &= 7308^3 + 212079^3 \\ &= 129367^3 + 194642^3 \\ &= 160534^3 + 175463^3 \end{aligned}$$

5. Other Results

By combining results of the search as described in Section 2, it was possible to generate several additional primitive sums beyond the search range. For example, the following are some 5-way sums

and a 6-way sum:

$$\begin{aligned}
490593422681271000 &= 48369^3 + 788631^3 \\
&= 233775^3 + 781785^3 \\
&= 285120^3 + 776070^3 \\
&= 543145^3 + 691295^3 \\
&= 579240^3 + 666630^3
\end{aligned}$$

$$\begin{aligned}
6355491080314102272 &= 103113^3 + 1852215^3 \\
&= 580488^3 + 1833120^3 \\
&= 788724^3 + 1803372^3 \\
&= 1150792^3 + 1690544^3 \\
&= 1462050^3 + 1478238^3
\end{aligned}$$

$$\begin{aligned}
27365551142421413376 &= 167751^3 + 3013305^3 \\
&= 265392^3 + 3012792^3 \\
&= 944376^3 + 2982240^3 \\
&= 1283148^3 + 2933844^3 \\
&= 1872184^3 + 2750288^3
\end{aligned}$$

$$\begin{aligned}
1199962860219870469632 &= 591543^3 + 10625865^3 \\
&= 935856^3 + 10624056^3 \\
&= 3330168^3 + 10516320^3 \\
&= 6601912^3 + 9698384^3 \\
&= 8387550^3 + 8480418^3
\end{aligned}$$

$$\begin{aligned}
111549833098123426841016 &= 1074073^3 + 48137999^3 \\
&= 8787870^3 + 48040356^3 \\
&= 13950972^3 + 47744382^3 \\
&= 24450192^3 + 45936462^3 \\
&= 33784478^3 + 41791204^3
\end{aligned}$$

$$\begin{aligned}
8230545258248091551205888 &= 112393173^3 + 201891435^3 \\
&= 17781264^3 + 201857064^3 \\
&= 63273192^3 + 199810080^3 \\
&= 85970916^3 + 196567548^3 \\
&= 125436328^3 + 184269296^3 \\
&= 159363450^3 + 161127942^3
\end{aligned}$$

These sums were known to me prior to my discovery of Ta(5), and are very small compared to what can be obtained by the methods described in [HW54]. 8230545258248091551205888 is currently the least known 6-way sum.

Moments of Generalized Motzkin Paths

Robert A. Sulanke
Boise State University
Boise, ID 83725 USA
Email address: sulanke@math.idbsu.edu

Abstract: Consider lattice paths in the plane allowing the steps (1,1), (1,-1), and (w,0), for some nonnegative integer w. For $n > 1$, let $E(n,0)$ denote the set of paths from (0,0) to (n,0) running strictly above the x-axis except initially and finally. Generating functions are given for sums of moments of the ordinates of the lattice points on the paths in $E(n,0)$. In particular, recurrencess are derived for the cardinality, the sum of the first moments (essentially the area), and the sum of the second moments for paths in $E(n,0)$. These recurrences unify known results for w= 0, 1, 2, i.e. those for the Dyck (or Catalan), Motzkin, and Schröder paths, respectively. The sum of the second moments is seen to equal the number of unrestricted paths running from (0,0) to (0,n-2).

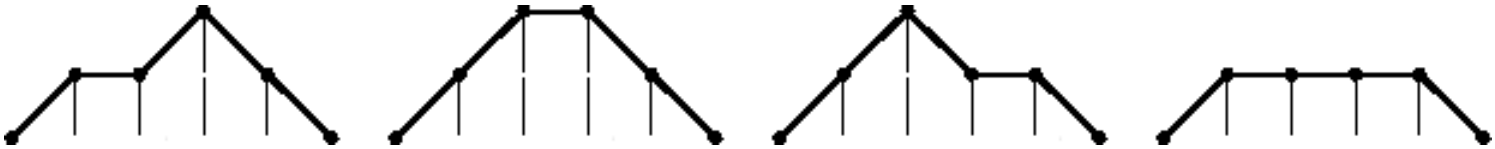
Contents:

1. Introduction: the paths and their moments

Let w be a fixed nonnegative integer. We will consider those lattice paths in the Cartesian plane whose permitted step types are the *up diagonal step* (1,1) denoted by U, the *down diagonal step* (1,-1) denoted by D, and the *horizontal step* (w,0) denoted by H. When w= 0, only U-steps and D-steps are permitted. We weight the steps by assigning 1 to each U-step, 1 to each D-step, and an indeterminate t to each H-step. The t-weight of a path P, denoted by $|P|$, is the product of the weights of its steps; and the t-weight of a set of paths S, denoted by $|S|$, is the sum of the t-weights of the paths in S.

Often we will suppress the parameter w and the indeterminate t in our notation. Let $U(x,y)$ denote the set of all *unrestricted* lattice paths using the permitted step types and running from (0,0) to (x,y). We define the set of *generalized Motzkin paths*, denoted by $M(x,y)$, to be the set of paths in $U(x,y)$ that never run below the x-axis except initially and perhaps finally. Of particular interest is the set of *elevated paths*, denoted by $E(x,y)$, consisting of those paths in $M(x,y)$ that never touch the x-axis except initially and perhaps finally. For an example, see Figure 1 and the left column of Table 1 which give the four paths in $E(5,0)$ when $w = 1$.

Figure 1: The 4 elevated Motzkin paths of $E(5,0)$, for $w = 1$, bound a total area of 20 units. Equivalently the sum of their path ordinates is 20.



Let $f_n(w)$ denote $|E(n,0)|$ for $n >= 2$, with $f_0(w) = f_1(w) = 0$. For $t = 1$, there are three classical sequences covered by this notation, specifically for $w = 0$, 1 or 2. When $w = 0$, there are no horizontal steps and the paths of $E(n,0)$ are the so-called elevated Dyck (or Catalan) paths; the corresponding sequence $(f_n(0))_{n >= 2} = (1, 0, 1, 0, 2, 0, 5, 0, 14, \ldots)$ is the sequence of (aerated) Catalan numbers. For $w = 1$ and $t = 1$, $(f_n(1))_{n >= 2}$ is the sequence of Motzkin numbers. For $w = 2$ and $t = 1$, $(f_n(2))_{n >= 2}$ is the sequence of (aerated) large Schröder numbers. See Table 2 in Section 7. In 1948, using different indexing, Motzkin [12] introduced the sequence $(f_n(1))_{n >= 2}$, where $f_n(1)$ denotes the number of ways to join n-2 points on a circle by nonintersecting chords. Donaghey and Shapiro [4] made an early study of this sequence which included lattice paths equivalent to those of $M(n,0)$ with $w = 1$.

Consider a path P in $E(n,0)$ as a rectilinear curve. Let (0, $P(0)$), (1, $P(1)$), ..., (n, $P(n)$) be the list of *all* lattice points (points with integer coordinates) on the path P. We will refer to the values $P(0)$, $P(1)$, $P(2)$, ..., $P(n)$ as the *path ordinates* of P. Define the r^{th} moment of P to be

$$\frac{1}{n-1}\sum_{j=1}^{n-1} P(j)^r.$$

The zeroth moment of P equals 1. By the elementary formula for the area of a trapezoid, we see that $\sum_{0<j<n} P(j)$ equals the area bounded by the path P and the x-axis.

path	contribution	contribution	contribution	contribution
	to $f_5(1)$	to $g_5(1)$	to total area	to $h_5(1)$
UHUDD	t	$5t/4$	5	$7t/4$

UUHDD	t	$6t/4$	6	$10t/4$
UUDHD	t	$5t/4$	5	$7t/4$
UHHHD	t^3	$4t^3/4$	4	$4t^3/4$

Table 1: This table gives the contributions to $f_5(1) = 3t+t^3$, $g_5(1) = 4t+t^3$, $h_5(1) = 6t+t^3$, and the total area by the the four paths of $E(5,0)$ for $w = 1$.

For fixed $w >= 0$ and for $n >= 2$, we define the following *sums of t-weighted moments* for the path set $E(n,0)$:

$$f_n(w) = \sum_{P \in E(n,0)} |P| \tag{1}$$

$$a_n(w) = \sum_{P \in E(n,0)} |P| \sum_{j=1}^{n-1} P(j) \tag{2}$$

$$g_n(w) = \sum_{P \in E(n,0)} \frac{|P|}{n-1} \sum_{j=1}^{n-1} P(j) \tag{3}$$

$$h_n(w) = \sum_{P \in E(n,0)} \frac{|P|}{n-1} \sum_{j=1}^{n-1} P(j)^2. \tag{4}$$

The main results of this paper are the three recurrences for these sequences, given uniformly in equations (5), (6), and (7), and the generating function for the factorial moments given in Proposition 5. In Section 2 we state these recurrences, which we then establsh by generating function methods in Sections 3, 4, and 5. In Section 6 we prove a surprising result relating second moments to central unrestricted numbers. In Section 7 we will give some examples of these sequences.

2. The recurrences

For any $w >= 0$, consider the following unified set of recurrences for the sequences, $(f_n)_{n >= 2}$, $(g_n)_{n >= 2}$, and $(h_n)_{n >= 2}$, which we have defined above in terms of t-weighted elevated paths:

$$n\, f_n = 4(n\text{-}3)\, f_{n\text{-}2} + (2n - 3\,w)\, t\, f_{n\text{-}w} - (n - 3\,w)\, t^2\, f_{n\text{-}2w}, \tag{5}$$

$$(n\text{-}1)g_n = 4(n\text{-}3)\, g_{n\text{-}2} + (2n - 2w\text{-}2)tg_{n\text{-}w} - (n - 2\, w\text{-}1)t^2\, g_{n\text{-}2w}, \tag{6}$$

$$(n\text{-}2)h_n = 4(n\text{-}3)\, h_{n\text{-}2} + (2n - w - 4\,)th_{n\text{-}w} - (n - w - 2)t^2\, h_{n\text{-}2w}. \tag{7}$$

These recurrences are valid except for certain initial values, as specified in the propositions below. We first state these recurrences for the known case of elevated Dyck (or Catalan) paths.

Proposition 1. For $w = 0$, the sequences $(f_n(0))_{n >= 2}$, $(g_n(0))_{n >= 2}$, and $(h_n(0))_{n >= 2}$ satisfy

$$n\, f_n(0) = 4(n\text{-}3)\, f_{n\text{-}2}(0) \tag{8}$$

$$(n\text{-}1)\, g_n(0) = 4(n\text{-}3)\, g_{n\text{-}2}(0) \tag{9}$$

$$(n\text{-}2)\, h_n(0) = 4(n\text{-}3)\, h_{n\text{-}2}(0) \tag{10}$$

for $n >= 3$, subject to the initial conditions that $f_n(0) = g_n(0) = h_n(0) = 0$ for $n < 2$ and $f_2(0) = g_2(0) = h_2(0) = 1$.

The proof of this Proposition is covered by the proofs of Propositions 2, 3, and 4. Recurrence (8) dates from about 1758, when Euler [5] recorded it, slightly re-indexed, when he and Segner [14] were considering counting triangulations of convex polygons. See Section 8. It follows immediately that, for $k >= 0$,

$$f_{2k+2}(0) = \frac{1}{k+1}\binom{2k}{k}, \quad g_{2k+2}(0) = \frac{4^k}{2k+1}, \quad \text{and} \quad h_{2k+2}(0) = \binom{2k}{k}. \tag{11}$$

For $w >= 1$, we have the following more general result, which in proved in the next section:

Proposition 2. For $w >= 1$, the sequence $(f_n)_{n >= 2}$ satisfies recurrence (5) for $n > 2w$, with initial values satisfying $f_n = f_n(0) + (n\text{-}w\text{-}1)t\, f_{n\text{-}w}(0)$ for $n <= 2w$.

With $a_n = a_n(w)$ denoting the t-weighted area, $\sum_{P \in E(n,0)} |P| \cdot [\text{area under } P\,]$, the trapezoidal area formula shows that $a_n = (n\text{-}1)g_n$ for all $n >= 2$. The following result, proved in Section 5, generalizes one of Kreweras [9] for $w = 2$ and $t = 1$.

Proposition 3. For $w >= 1$, $(g_n)_{n >= 2}$ satisfies recurrence (6) for $n > w + 2$, with initial values $g_n = g_n(0)$ for $n <= w + 2$, and $g_{w+2} = g_{w+2}(0) + t$. Equivalently, for $w >= 1$, the sequence $(a_n)_{n >= 2}$ satisfies the recurrence

$$a_n = 4\,a_{n-2} + 2\,ta_{n-w} - t^2 a_{n-2w} \tag{12}$$

for $n > w + 2$, with initial values $a_n = (n-1)g_n(0)$ for $n <= w + 2$, and $a_{w+2} = (w+1)g_{w+2}(0) + (w+1)t$.

We remark that (10) is a well-known recurrence for the central binomial coefficients. In the case when $w = 1$ with $t = 1$, recurrence (7) dates from 1764, as Euler [6] proved that the central trinomial coefficients satisfy this recurrence when appropriately re-indexed. Our knowledge that these central coefficients are solutions to the recurrences (7) and (10) led to an interesting relationship between second moments and central numbers of the form $|U(n,0)|$ for arbitrary w. Specifically, in Section 6 we will see that $|U(n-2, 0)|$ satisfies a recurrence that is also satisfied by $h_n(t)$; thus we have a proof of identity (13) below. The proof of the first part of the following appears in Section 5.

Proposition 4. For $w >= 1$, the sequence $(h_n)_{n >= 2}$ satisfies recurrence (7) for $n >= 3$, with the initial values $h_n = 0$ for $n < 2$ and $h_2 = 1$. Moreover, for any w and for $n >= 2$,

$$h_n = |U(n-2,0)|. \tag{13}$$

3. Enumerating restricted paths

Consider the generating function $M(z) = \sum_{n\geq 0} |M(n,0)|\, z^n$. With the exception of the point path, each path in $M(n,0)$ either begins with an H-step or immediately leaves the x-axis and then later returns for a first time. Consequently, with L denoting $\cup_{n>=0} M(n,0)$ and with juxtaposition indicating concatenation, we have a decomposition that defines L recursively:

$$L = M(0,0) \cup HL \cup ULDL.$$

With z marking a horizontal unit and with t marking each H-step, the decomposition yields

$$M(z) = 1 + tz^w\, M(z) + z^2 M(z)^2, \tag{14}$$

and hence

$$M(z) = (1 - tz^w - \sqrt{1 - 4z^2 - 2tz^w + t^2 z^{2w}}\,)/2z^2. \tag{15}$$

Let $F(z) = \sum_{n \geq 2} f_n z^n$. Since $f_{n+2} = |M(n,0)|$,

$$F(z) = (1 - tz^w - \sqrt{1 - 4z^2 - 2tz^w + t^2 z^{2w}})/2. \tag{16}$$

Note that the coefficient of z^n both in the power series for $F(z)$ and in the power series for

$$\Phi(z) = -(\sqrt{1 - 4z^2 - 2tz^w + t^2 z^{2w}})/2$$

must agree for all coefficients f_n, except for $n = 0$ or $n = w$. Logarithmic differentiation yields

$$(1 - 4z^2 - 2tz^w + t^2 z^{2w})\Phi'(z) + (4z + wtz^{w-1} - wt^2 z^{2w-1})\Phi(z) = 0.$$

Upon comparing coefficients we obtain a sequence of recurrences, where we denote the n^{th} recurrence in the sequence as

$$\text{RECUR}(n): \quad n f_n = 4(n\text{-}3) f_{n\text{-}2} + (2n - 3w) t f_{n\text{-}w} - (n - 3w) t^2 f_{n\text{-}2w}$$

This recurrence is valid, yielding Proposition 2, except when the term f_0 or the term f_w is present. The term f_w appears in four recurrences, namely, RECUR(n) for $n = w$, $n = w + 2$, $n = 2w$ and $n = 3w$. In the highest indexed recurrence of these four, namely,

$$\text{RECUR}(3w): \quad 3w f_{3w} = 4(3w\text{-}3) f_{3w\text{-}2} + 3wt f_{2w} - 0\, t^2 f_w,$$

there is no requirement placed on the value of f_w. Hence the recurrence of (5) is valid for $n > 2w$. We obtain the initial conditions for (5) by enumerating the ways to insert either none or one horizontal step in each of the appropriate paths of $E(n,0)$ for $w = 0$, for $n <= 2w$, which are enumerated in Proposition 1.

4. Factorial moments

Here we extend a method for summing path ordinates, given by Woan, Shapiro, and Rogers [21], to one for summing falling factorials of ordinates for paths of $E(n,0)$. For a positive integer r we will consider the t-weighted sum of the falling factorial moments, given by (with the divisor n - 1 missing)

$$\mu(n,r) = \sum_{P \in E(n,0)} |P| \sum_{0<i<n} (P(i))_r,$$

where $(k)_r$ denotes the falling factorial. That is, $(k)_r = k(k\text{-}1)_{r\text{-}1}$ for positive integer r and $(k)_0 = 1$. The formulation of the next proposition is based on the studies of Shapiro, Woan, and Getu [15] and of Chapman [3], both of which considered moments of all degrees for Dyck paths, with [3] considering rising moments.

Proposition 5. For integer r, $r >= 1$,

$$\sum_{n>=0} \mu(n,r) z^n = \frac{r! z^2 (1+(w-1)tz^w)(1-tz^w - \sqrt{(1-tz^w)^2 - 4z^2}\ )^{r-1}}{2^{r-1}(\sqrt{(1-tz^w)^2-4z^2}\ )^{r+1}}.$$

Proof. We use the following temporary notation. Let $B(A) = 1$ if A is a true statement and $B(A) = 0$ if is false. Let ``($i$,$k$) step end of $P$'' abbreviate ``(i,k) is an end point of a step of path P''. Let ``($i$,$k$) interior of $P$'' abbreviate ``(i,k) is an interior lattice point on a horizontal step of path P''. Such a horizontal step will run from (j,k) to (j+w,k) in our notation. Let Q be any path in $E(j,k)$. Let R and R' denote arbitrary paths that never pass below the x-axis with R running from (j,k) to (n,0) and R' running from (j+w,k) to (n,0). By symmetry, R can be matched with a path in $E(n\text{-}j, k)$. Let $m(j,k)$ denote $|E(j,k)|$.

For $n >= 2$,

$$\begin{aligned}
\mu(n,r) &= \sum_{P \in E(n,0)} |P| \sum_{0<i<n} (P(i))_r \\
&= \sum_{P} \sum_{k>0} \sum_{0<i<n} (k)_r |P|\ B(P(i)=k) \\
&= \sum_{k>0} \sum_{0<i<n} \sum_{P} (k)_r |P|\ B(P(i)=k) \\
&= \sum_{k>0} (k)_r \sum_{0<i<n} \sum_{P} |P|\ (B((i,k) \text{ step end of } P\ ) + B((i,k) \text{ interior of } P\ )) \\
&= \sum_{k>0} (k)_r \sum_{j>0} [\ \sum_{Q,R} |Q| \cdot |R| + \sum_{Q,R'} (w-1)t|Q| \cdot |R'|\ ] \\
&= \sum_{k} (k)_r\ [\ \sum_{j} m(j,k)m(n-j,k) + (w-1)t \sum_{j} m(j,k)m(n-j-w,k)\ ]
\end{aligned}$$

With M denoting $M(z)$, we claim that the following string of equations holds:

$$\sum_{n>=2} \mu(n,r) z^n = \sum_k (k)_r \left[\sum_n \sum_j m(j,k) m(n-j,k) z^n \right.$$
$$\left. +(w-1) t z^w \sum_n \sum_j m(j,k) m(n-j-w,k) z^{n-w} \right]$$
$$= [1+(w-1)tz^w] \sum_k (k)_r (zM)^{2k} \tag{17}$$
$$= (1+(w-1)tz^w) \frac{r!(z^2M^2)^r}{(1-z^2M^2)^{r+1}} \tag{18}$$
$$= r!(1+(w-1)tz^w) \cdot \frac{(z^2M^2)}{(1-z^2M^2)^2} \cdot \frac{(z^2M^2)^{r-1}}{(1-z^2M^2)^{r-1}} \tag{19}$$
$$= \frac{r!z^2(1+(w-1)tz^w)(1-tz^w-\sqrt{(1-tz^w)^2-4z^2}\ )^{r-1}}{2^{r-1}(\sqrt{(1-tz^w)^2-4z^2}\ )^{r+1}}.$$

To establish this string we first note that each path in $E(j,k)$ must depart from each line $y = c$, for integer c, $0 <= c < k$, for a last time. Hence a simple convolution argument shows that the generating function for $m(j,k)$ satisfies

$$\sum_j m(j,k) z^j = (zM(z))^k. \tag{20}$$

This implies (17). Line (18) is a consequence of binomial theorem in the form
$r!y^r(1-y)^{-r-1} = \sum_{k>=r}(k)_r y^k$.

To handle the middle fraction in (19) we use (14) twice:

$$\begin{aligned}\frac{z^2M^2}{(1-z^2M^2)^2} &= \frac{z^2M^2}{((1-tz^w)M-2)^2}\\ &= \frac{z^2M^2}{(1-tz^w)^2M^2+4(1-(1-tz^w)M)}\\ &= \frac{z^2M^2}{(1-tz^w)^2M^2-4z^2M^2}\\ &= \frac{z^2}{(1-tz^w)^2-4z^2}.\end{aligned}$$

To handle the last fraction in (19) use the following result derived from formula (15), with $\Delta = (1-tz^w)^2 - 4z^2$:

$$\begin{aligned}\frac{z^2M^2}{1-z^2M^2} &= \frac{(2z^2M)^2}{4z^2-(2z^2M)^2}\\ &= \frac{(1-tz^w-\sqrt{\Delta})^2}{4z^2-(1-tz^w)^2+2(1-tz^w)\sqrt{\Delta}-\Delta}\\ &= \frac{(1-tz^w-\sqrt{\Delta})^2}{-2\Delta+2(1-tz^w)\sqrt{\Delta}}\\ &= \frac{1-tz^w-\sqrt{\Delta}}{2\sqrt{\Delta}}.\end{aligned}$$

5. Area and second moments

Setting *r* = 1 in Proposition 5, we obtain a generating function for sums of the *t*-weighted areas:

$$\sum_{n>=2} a_n z^n = \frac{z^2(1+(w-1)tz^w)}{(1-tz^w)^2-4z^2}. \tag{21}$$

Then the first part of Proposition 3 follows upon comparing coefficients in (21), rewritten as

$$(1-4z^2-2tz^w+t^2z^{2w})\sum_{n>=2}a_nz^n=z^2(1+(w-1)tz^w),$$

and checking the obvious initial conditions. Recurrence (6) is then immediately derived from (12) by (2) and (3).

There is an interesting corollary when $w = 1$. Using partial fractions decomposition, the generating function (21) yields

$$A(z)=\frac{z}{4}\left(\frac{1}{1-(2z+tz)}-\frac{1}{1+(2z-tz)}\right),$$

and so, for $w = 1$ and $n >= 2$,

$$a_n=\frac{1}{4}((t+2)^{n-1}-(t-2)^{n-1}).$$

To obtain the generating function for the second moments, $H(z)=\sum_{n>=2}h_nz^n$, we use the following, where the constant of integration is checked to be 0:

$$\begin{aligned}
H(z) &= \sum_{n>=2}\sum_{P\in E(n,0)}\frac{|P|}{n-1}\sum_j((P(j))_1+((P(j))_2)z^n \\
&= z\sum_{n>=2}\frac{1}{n-1}(\mu(n,1)+\mu(n,2))z^{n-1} \\
&= z\int\sum_{n>=2}z^{-2}(\mu(n,1)+\mu(n,2))z^n\,dz \\
&= z\int\sum_{n>=2}\frac{(1+(w-1)tz^w)(1-tz^w)}{(1-4z^2-2tz^w+t^2z^{2w})^{3/2}}\,dz
\end{aligned}$$

$$= \frac{z^2}{\sqrt{1-4z^2-2tz^w+t^2z^{2w}}}. \qquad (22)$$

Let $\Psi(z) := \sum_{n>=0} h_{n+2} z^n = H(z)/z^2$. From (22), differentiation with respect to z yields

$$(1-4z^2-2tz^w+t^2z^{2w})\Psi'(z) - (4z+wtz^{w-1}-wt^2z^{2w-1})\Psi(z) = 0.$$

Hence

$$(nh_{n+2} - 4\,(n-2)\,h_n - 2\,(n-w+2)t\,h_{n-w+2} + (n-2w+2)\,t^2\,h_{n-2w+2})$$
$$- (4\,h_n + wt\,h_{n-w+2} - 2\,wt^2\,h_{n-2w+2}) = 0.$$

Shifting the index yields the first part of Proposition 4, namely (7), where the initial conditions are easily checked.

6. Relating second moments to the central numbers

We begin with a straightforward extension of the André reflection method to paths that contain horizontal steps. We obtain the following string of bijections:

$M(n,0)$ = $U(n,0)$ - { P in $U(n,0)$: P intersects the line $y = -1$}

<-> $U(n,0)$ - { P' : P' runs from (0,-2) to (n,0) } (23)

<-> $U(n,0)$ - $U(n,2)$. (24)

To obtain (23), observe that each path P in the set { P in $U(n,0)$: P intersects the line y=-1} can be decomposed as $P = QR$, where Q terminates at the first intercept of the line $y = -1$ by the path P. Let Q' denote the reflection of the path Q about the line $y = -1$. The matching $P = QR$ with $P' = Q'R$ now defines the bijection indicated in (23). A simple translation yields (24).

Let $u(x,y)$ denote $|U(x,y)|$. Since any path to the point $(n+1,k)$ must end with a U, D, or H step, we have

$$u(n+1,k) = u(n, k-1) + u(n, k+1) + t\,u(n-w+1)$$

and $u(n, -1) = u(n, 1)$. Using (24) and these identities, we obtain

$$2f_{n+2} = 2u(n,0) - 2u(n,2)$$
$$= 4\,u(n,0) - 2u(n+1,1) + 2\,t\,u(n-w+1,1)$$
$$= 4\,u(n,0) + t\,u(n-w+2,0) - u(n+2,0) - (t^2u(n-2w+2,0) - t\,u(n-w+2,0))$$

$$= -u(n+2,0) + 4\,u(n,0) + 2\,t\,u(n-w+2,0) - t^2\,u(n-2w+2,0). \tag{25}$$

Returning to results (16) and (22), we observe that they imply

$$1 - tz^w - 2\sum_{n>=2} f_n z^n = \frac{1 - 4z^2 - 2tz^w + t^2 z^{2w}}{\sqrt{1 - 4z^2 - 2tz^w + t^2 z^{2w}}} \qquad \text{and}$$

$$z^{-2}\sum_{n>=2} h_n z^n = \frac{1}{\sqrt{1 - 4z^2 - 2tz^w + t^2 z^{2w}}}.$$

Comparing coefficients yields the mixed recurrence

$$2f_{n+2} = -h_{n+4} + 4\,h_{n+2} + 2t\,h_{n-w+4} - t^2\,h_{n-2w+4}. \tag{26}$$

But this recurrence for f_n and h_n has the same form as that for f_n and $u(n,0)$ given in (25). Since the initial conditions agree, we have the second statement of Proposition 4 by induction. Moreover, we have that the generating function for $u(n,0) = |U(n,0)|$ satisfies

$$\sum_{n>=0} |U(n,0)|z^n = \Psi(z).$$

We have omitted the explicit formulas for f_n and h_n, which are weighted sums of Catalan and binomial coefficients, respectively. In light of (13), we can find these sums by counting the ways to insert horizontal steps into the respective paths.

The first formula of (11) yields the following known relation between the Catalan numbers and the central binomial numbers. Upon replacing $2k+2$ by n in that formula, we find for $h = 0$, $n >= 2$ and n even,

$$f_n(0) = \frac{1}{(n-2)/2+1}\binom{n-2}{(n-2)/2} = \frac{1}{2(n-1)}\binom{2n}{n} = \frac{|U(n,0)|}{2(n-1)}.$$

The following gives an analogous result for general w:

Proposition 6. For $n > 2w$,

$$f_n = \frac{|U(n,0)| + (w-2)t|U(n-h,0)| + t^2(1-w)|U(n-2w,0)|}{2(n-1)}.$$

Proof: One can substitute expressions given by recurrence (7) and (26) into (5), which is valid for n > 2w. Our substitutions were facilitated using a computer algebra program. Equation (13) then is applied to complete the proof.

7. Examples

In Table 2, we record the previously studied, and named, examples satisfying the recurrences in Propositions 1 to 4, along with their reference number from Sloane's *On-Line Encyclopedia of Integer Sequences* [16]. These examples correspond to sets of elevated paths, $(E(n,0))_{n>=2}$, so in the table $n = 2, 3, 4 \ldots$ and $k = 1, 2, 3 \ldots$.

t	Sequence		Name	Sloane
1	$f_n(0)$	1, 0, 1, 0, 2, 0, 5, 0, 14, 0, 42	aerated Catalan nos.

Table 2

In Table 2, the ``walks on cubic lattice'' entry illustrates one role played by the indeterminate *t*. Corresponding to the case *w* = 1 and *t* = 4, Guy [7] found f_n (mildly re-indexed) to count the walks on a three-dimensional lattice that use unit steps in all six standard directions (i.e. the positive and negative unit steps parallel to the three axes), that start at (0,0,0), end on the *x*-*y* plane, and never pass beneath that plane. More generally, for *m* > 3, *w* = 1 and $t = 2^{m-1}$, we find that f_n counts the walks of length *n*-2 on the *m*-dimensional integer lattice that use the unit steps in all 2^m standard directions, start at the origin, end on the hyperplane, $x_1 + \ldots + x_{m-1} = 0$, and never pass through a lattice point $(x_1, \ldots, x_m)$ for which $x_m < 0$. To see this we identify the unit step in the positive x_m direction with the *U*-step, the unit step in the negative x_m direction with the *D*-step, and the set of the other 2^{m-1} steps, none of which affects the distance from the hyperplane, $x_1 + \ldots + x_{m-1} = 0$, with a weighed *H*-step.

Another example utilizing *t* is the enumeration of the horizontal steps over all paths in $E(n,0)$. Let $f_{n,k}$ denote the number of paths in $E(n,0)$ having *k* horizontal steps. We find that the generating function for the total number of horizontal steps on paths having *k* horizontal steps satisfies

$$\begin{aligned}\sum_{n>=0}\sum_{k>=0} k f_{n,k} t^k z^n &= \sum_{n>=0} \frac{d}{dt} f_n z^n \\ &= \frac{d}{dt} F(z) \\ &= z^w(-1 + (1 - tz^w)\Psi(z)).\end{aligned}$$

Consequentially, the total number of horizontal steps is expressible in terms of *t*-weighted unrestricted paths as follows: for *n* >= 0,

$$\sum_{k>=0} k f_{n,k} t^k = (u(n-w,0) - tu(n-2w,0))/2 = u(n-w-1,1).$$

8. Related Studies

As noted in [8], in the 1730's, Ming An-tu, a Mongolian mathematician, was aware of the Catalan numbers, $(c_n)_{n>=0}$

= (1, 1, 2, 5, 14, ...), in a non-combinatorial sitting. He discovered several recurrence for these numbers including the well-known convolution recurrence, $c_n = c_0c_{n-1} + c_1c_{n-2} + \ldots + c_{n-1}c_0$. In about 1758, Euler [5] and Segner [14] made the first European discovery of these numbers while counting the triangulations of a convex polygon. They observed that c_{n-2} is the number of ways to draw non-crossing diagonals between the vertices of a convex n-gon. Segner recorded and proved the above convolution recurrence in terms of triangulations of polygons. Euler observed, without giving a proof, that $c_n = (4n-2)/(n+1)\, c_{n-1}$, which is essentially (8), and then gave a closed form for c_n as a product of ratios that reduces to a ratio of product as in the first formula of (11).

There are several studies on lattice paths, in addition to those mentioned previously, that have influenced our results. Barcucci, Pinzani, and Sprugnoli [1] have made a systematic analysis containing recurrences - many mixed - for the Motzkin paths, i.e. $w = 1$ and $t = 1$, involving the sequences for count, central entries (central trinomial coefficients), and other related statistics. Recently the author [20] has established (5), (6), and (7) bijectively for Motzkin paths.

Besides Kreweras [9], Bonin, Shapiro, and Simion [2] have considered elevated Schröder paths and the recurrence (12) for $w = 2$. For $w = 2$ the author [18] has employed bijective schema to establish recurrences (5) and (12); in [19] he has considered (5), (6), and (7) in terms of parallelogram polyominoes. Most recently for $w = 2$, Merlini, Sprugnoli, and Verri [11] have given additional proofs for (5) with essentially an arbitrary t, while Pergola and Pinzani [13] have developed an encoding relating area to path count to obtain (12) bijectively.

Merlini, Sprugnoli, and Verri [10] have developed generating functions for the total area bounded by lattice paths where the permitted steps are more general than our U, D, and H. For Dyck paths, Chapman [3] has considered the generating functions for the sums of path moments and the relationship between the generating functions for elevated versus non-elevated paths.

Stanley [17] has given an extensive treatment of generalizations of the central entries, $|U(n,0)|$, under the name ``diagonals". In [17] his results for *differentiably finite power series* relate to our use of the generating functions Φ and Ψ of Sections 3 and 5. Correspondingly, he considered *polynomially recursive sequences*, for which our sequences (f_n), (g_n), and (h_n) are prime examples.

Acknowledgements: The author thanks Lou Shapiro for sharing an early draft of [21] and for his suggestions improving this paper. The author also thanks Joyce Sulanke for her assistance in translating [5], [6], and [14].

The Kaprekar Numbers

Douglas E. Iannucci

St. Thomas, VI 00802
Email address: diannuc@uvi.edu

Abstract: The (decimal) *n*-Kaprekar numbers are defined and are shown to be in one-one correspondence with the unitary divisors of $10^n - 1$. In particular, this establishes the correctness of an algorithm for generating the Kaprekar numbers proposed by Charosh in 1981. The even perfect numbers are shown to be Kaprekar numbers in the binary base.

1. INTRODUCTION

The *Kaprekar numbers* (sequence A006886 in **[4]**) were introduced by the eponymous D. R. Kaprekar **[3]** in 1980. They have been the subject of several articles, and are mentioned in David Wells's *Dictionary of Curious and Interesting Numbers* **[5].**

What makes the Kaprekar numbers curious or interesting? Let's consider an example. The number 703 is Kaprekar because

$$703^2 = 494209 \quad \text{and} \quad 494 + 209 = 703 .$$

Here are some further examples:

$9^2 = 81$,	$8 + 1 = 9$;
$45^2 = 2025$,	$20 + 25 = 45$;
$297^2 = 88209$,	$88 + 209 = 297$;
$4879^2 = 23804641$,	$238 + 4641 = 4879$;
$17344^2 = 300814336$,	$3008 + 14336 = 17344$;

$$538461^2 = 289940248521 , \qquad 289940 + 248521 = 538461 .$$

Formally, an n-Kaprekar number $k >= 1$ (for $n = 1, 2, ...$) satisfies the pair of equations

$$k = q + r ,$$

$$k^2 = q * 10^n + r$$

where $q >= 1$ and $0 <= r < 10^n$. As the 5-Kaprekar number $k = 4879$ shows, r may have fewer than n digits. We adopt the convention that 1 is an n-Kaprekar number for all $n >= 1$, since

$$1^2 = 0 * 10^n + 1, \qquad 1 = 0 + 1 ;$$

but by fiat 0 and 10^m for $m >= 1$ are not Kaprekar numbers.

Kaprekar **[3]** listed 9 as a Kaprekar number, but failed to list 99, 999, ... However, $10^n - 1$ (for all $n >= 1$) is n-Kaprekar since

$$\underbrace{99\ldots99}_{n\text{ nines}}{}^2 = \underbrace{9\ldots998}_{n-1\text{ nines}}\underbrace{0\ldots001}_{n-1\text{ zeros}} , \qquad \underbrace{9\ldots998}_{n-1\text{ nines}} + \underbrace{0\ldots001}_{n-1\text{ zeros}} = \underbrace{99\ldots99}_{n\text{ nines}} ;$$

that is,

$$(10^n - 1)^2 = (10^n - 2) * 10^n + 1 , \qquad 10^n - 1 = (10^n - 2) + 1 .$$

Charosh **[2]** noted Kaprekar's omission of the numbers $10^n - 1$ ($n >= 1$), as well as the 6-Kaprekar numbers 181819 and 818181. In fact, Charosh correctly devised a method by which to construct Kaprekar numbers of any size. In this paper, we will refine Charosh's result by establishing a bijection between the n-Kaprekar numbers and the unitary divisors of $10^n - 1$ (thus refining and proving Charosh's result). Recall that a is a *unitary divisor* of m if $ab = m$ and $(a, b) = 1$.

2. THE MAIN RESULT

For each integer $N > 1$, let $K(N)$ denote the set of positive integers k for which there exists integers q and r such that

$$k^2 = qN + r \qquad (0 <= r < N) \qquad \textbf{(1)}$$

$$k = q + r \quad . \qquad \textbf{(2)}$$

As a matter of convention, we shall ignore the vacuous solution $k = N$ (for which $q = N$ and $r = 0$). **(1)** and **(2)** imply

$$k(k - 1) = q(N - 1) \qquad \textbf{(3)}$$

Since we disregard the vacuous solution, we have $1 <= k <= N - 1$ (for if $k >= N$ then **(3)** implies $q > k$, contradicting **(2)**).

The set $K(N)$ is nonempty, for always 1 is in $K(N)$. Suppose k were in $K(N)$. Since $(k, k - 1) = 1$, it follows from **(3)** that $d \mid k$ and $d' \mid k - 1$ for some positive d and d' such that $dd' = N - 1$ and $(d, d') = 1$. Let $k' = N - k$. Because $1 <= k <= N - 1$, we have $k' > 0$. Since $k' = (N - 1) - (k - 1)$, we have $d' \mid k'$. Thus $k = dm$ and $k' = d'm'$ for some positive m and m', whence follows

$$dm + d'm' = N = dd' + 1 \qquad \textbf{(4)}$$

Definition: If $(a , b) = 1$, we denote by ***Inv***(a , b) the least positive integer m such that $am = 1 \pmod b$. It follows that $m =$ ***Inv***(a , b) if and only if $1 <= m < b$ and $am = 1 \pmod b$.

It is not difficult to show the next result.

Lemma 1: Suppose $(a , b) = 1$. Then $m =$ ***Inv***(a , b) and $n =$ ***Inv***(b , a) if and only if m and n are positive and $am + bn = ab + 1$.

Applying Lemma 1 to **(4)** gives

$$k = d\,\textbf{Inv}(d , d') ; \qquad k' = d'\,\textbf{Inv}(d ', d) . \qquad \textbf{(5)}$$

Conversely, let $dd' = N - 1$, $(d, d') = 1$, and let $m =$ ***Inv***(d, d') and $m' =$ ***Inv***(d', d). Then by Lemma 1 we have $dm + d'm' = N$. Therefore

$$\begin{aligned} d^2m^2 &= (N - d'm')^2 \\ &= N^2 - N\,d'm' - (dm + d'm')\,d'm' + (d'm')^2 \\ &= N^2 - N\,d'm' - mm'dd' \\ &= (N - d'm' - mm')\;N + mm' . \end{aligned}$$

Thus

$$\begin{aligned} (dm)^2 &= (N - d'm' - mm')\,N + mm' \qquad (mm' < N) , \\ dm &= (N - d'm' - mm') + mm' . \end{aligned}$$

That is, dm satisfies **(1)** and **(2)** (with $q = N - d'm' - mm'$ and $r = mm'$), whence dm is in $K(N)$. Note that $d'm'$ is in $K(N)$ by symmetry. We have proved the following results:

Theorem 1: k is in $K(N)$ if and only if $k = d\,\mathbf{Inv}(d, (N\text{-}1)/d)$ for some unitary divisor d of $N - 1$.

Corollary A: The elements k of $K(N)$ occur in complementary pairs. For each k in $K(N)$, $N - k$ is in $K(N)$.

Let $w(M)$ denote the number of distinct primes dividing M; then M has exactly $2^{w(M)}$ unitary divisors. The following result is immediate:

Corollary B: $K(N)$ contains exactly $2^{w(N - 1)}$ elements.

The convention that N not be an element of $K(N)$ was taken to ensure the bijection between the elements of $K(N)$ and the unitary divisors of $N - 1$.

3. APPLICATIONS

If we let $N = 10^n$ for some $n >= 1$ in Theorem 1, we get the set of n-Kaprekar numbers, which is thus given by

$$K(10^n) = \{\, d\,\mathbf{Inv}(d , d') \;:\; dd' = 10^n - 1 ,\ (d , d') = 1 \,\}.$$

The following table lists all n-Kaprekar numbers k for $1 <= n <= 6$, along with the associated unitary divisors d of $10^n - 1$. These same Kaprekar numbers were given by Charosh **[2]**. By Corollary A, the n-

Kaprekar numbers occur in complementary pairs which sum to 10^n .

n	*d*	*k*	*n*	*d*	*k*	*n*	*d*	*k*	*n*	*d*	*k*
1	1	1	**4**	909	7272	**6**	11	181819	**6**	259	208495
	9	9		1111	7777		297	329967		6993	356643
2	1	1		9999	9999		77	38962		407	533170
	9	45	**5**	1	1		2079	187110		10989	681318
	11	55		9	77778		13	461539		2849	390313
	99	99		41	4879		351	609687		76923	538461
3	1	1		369	82656		91	318682		481	812890
	27	297		271	17344		2457	466830		12987	961038
	37	703		2439	95121		143	643357		3367	670033
	999	999		11111	22222		3861	791505		90909	818181
4	1	1		99999	99999		1001	500500		5291	994708
	9	2223	**6**	1	1		27027	648648		142857	142857
	11	2728		27	148149		37	351352		37037	851851
	99	4950		7	857143		999	499500		999999	999999
	101	5050		189	5292						

For example, consider $n = 3$: 27 and 37 are unitary divisors of $10^3 - 1 = 27 * 37$. Then ***Inv***(27, 37) = 11 and ***Inv***(37, 27) = 19, and we obtain the complementary 3-Kaprekar numbers 27 * 11 = 297 and 37 * 19 = 703.

The universal Kaprekar number 1 corresponds to the unitary divisor 1 of $10^n - 1$, which is why we allow unity as a Kaprekar number. For each $n >= 1$, we disallow 10^n as a Kaprekar number since it is the vacuous solution to **(1)** and **(2)** when $N = 10^n$.

If we let $N = b^n$ in Theorem 1 for some $b >= 2$ and $n >= 1$, we get the base-*b* generalization of the Kaprekar numbers. The case $b = 2$ is especially interesting.

Theorem 2: Every even perfect number is a Kaprekar number in the binary base.

Proof: Let $n >= 1$. It is clear that $2^n - 1$ and $2^n + 1$ are relatively prime, and that

$$2^{n-1}(2^n - 1) \equiv 1 \pmod{2^n + 1}, \qquad 0 < 2^{n-1} < 2^n + 1 .$$

Therefore $2^{n-1} = \mathbf{Inv}(2^n - 1, 2^n + 1)$, and so $2^{n-1}(2^n - 1)$ is in $K(2^{2n})$ by Theorem 1. It is well known that every even perfect number has the form $2^{n-1}(2^n - 1)$ where $2^n - 1$ is prime; hence the result follows. **QED**

To illustrate Theorem 2, we see that $28 = 2^2(2^3 - 1)$ is perfect and 6-Kaprekar in the binary base: $(28)_2 = 11100$, and

$$11100^2 = 1100010000 , \qquad 1100 + 010000 = 11100 .$$

Similarly, $b^{n-1}(b^n - 1)$ and $b^{n-1}(b^n + 1)$ are complementary $2n$-Kaprekar numbers in the base b whenever b is even. This pattern, among others, was noted by Charosh **[2]** in the case when $b = 10$.

4. CONCLUDING REMARKS

It is not worth compiling a more extensive list of Kaprekar numbers, since they can be obtained from the prime factorization of $10^n - 1$ cf. Brillhart et al. **[1]**.

Corollary B shows that the Kaprekar numbers have natural density zero.

A Study of Hyperperfect Numbers

Judson S. McCranie
1680 Westfield Court
Lawrenceville, GA 30043
USA
Email address: jud.mccranie@mindspring.com

Dedicated to the hyperperfect Anne McCranie, age 28 months.

Abstract: A number n is k-hyperperfect for some integer k if $n = 1 + k\,s(n)$, where $s(n)$ is the sum of the proper divisors of n. The 1-hyperperfect numbers are the familiar perfect numbers. This paper presents some theorems, conjectures and tables concerning hyperperfect numbers. All hyperperfect numbers less than 10^{11} have been computed. Evidence is presented suggesting that a published conjecture is false.

1. Introduction

Hyperperfect numbers are another generalization of perfect numbers, not to be confused with the better known multiply perfect, multiperfect, or k-fold perfect numbers.

Definition. An integer $n > 1$ is *k-hyperperfect* if it is 1 more than k times the sum of its proper divisors, for some positive integer k called the *index of perfection*. (See Guy, section B2; Roberts, page 177; Weisstein; Sloane, sequences A007592, A034897, A007593, A007594, etc.; Sloane and Plouffe, sequences M4150, M5113, M5121.)

This is equivalent to

$$n=k(sigma(n)-n-1)+1 \qquad \textbf{(1)}$$

where *sigma* is the usual sum of divisors function.

Notation. Unless otherwise noted, n denotes a hyperperfect number, k the index of perfection, p, q and r are odd primes with $p<q<r$, and i and k are positive integers.

All hyperperfect numbers less than 10^{11} have been tabulated in this study. There are 2190 hyperperfect numbers in this range, for 1932 different values of k. Only 85 of the hyperperfect numbers have odd index k, and 80 distinct odd values of k are represented. A total of 2105 of the hyperperfect numbers have even index k, and 1852 distinct even values of k are represented. All of these hyperperfect numbers are odd except for the 1-hyperperfect numbers (the familiar perfect numbers). Some individual larger hyperperfect numbers are given later.

2. The main tables

Table 1 is a list of the hyperperfect numbers less than 1,000,000 and their index of perfection k. Sequence A034897 is the left column and A034898 is the right column. (Omitting the entries with k=1 gives A007592.)

Table 2 is a list of the known hyperperfect numbers with $k <= 100$. The smallest known hyperperfect number for each value of k yields sequence A007594. Hyperperfect numbers less than 10^{11} are listed. Where there is no hyperperfect number less than 10^{11}, and larger hyperperfect numbers for this value of k are known, see Table 7.

3. Constructions

We consider the cases of even k and odd k separately.

Case 1: odd values of *k*. When k=1 these are the perfect numbers, and we will say no more about them. For the remainder of this section, we consider odd k>1, unless noted otherwise.

Theorem 1. If $k>1$ is an odd integer, $p=(3k+1)/2$ is prime, and $q=3k+4=2p+3$ is prime then p^2q is k-hyperperfect.

Proof. The proofs of Theorems 1, 2 and 3 are straightforward verifications and will be omitted.

An equivalent formulation is $p=6i-1$, $q=12i+1$, and $k=4i-1$, for some $i>0$. The proof does not hold if p is not of this form.

Theorem 1 also holds for $k=1$, giving the perfect number 28. Of course, the other 1-hyperperfect numbers are not of that form.

For odd $k>1$, there are 79 k-hyperperfect numbers less than 10^{11}. The smallest is $325 = 5^2*13$, which is 3-hyperperfect. The largest of these is $98015605201 = 3659^2*7321$, which is 2439-hyperperfect.

Sequences A034934, A034936, A034937, A034938, A002476 and A045309 give primes related to Theorem 1. Table 3 lists odd values of $k>1$ for which there are k-hyperperfect numbers. All (in fact all known k-hyperperfect numbers for odd $k>1$) are of the form of Theorem 1 (sequence A038536):

Table 3.

Odd values of *k* having *k*-hyperperfect numbers
3, 11, 19, 31, 35, 59, 75, 91, 111, 115, 131, 151, 179, 235, 255, 311, 335, 339, 371, 375, 399, 411, 431, 439, 495, 515, 531, 539, 551, 591, 619, 675, 739, 791, 795, 811, 839, 851, 871, 915, 951, 999, 1015, 1035, 1039, 1055, 1071, 1075, 1155, 1231, 1351, 1375, 1391, 1399, 1419, 1515, 1531, 1539, 1595, 1599, 1651, 1699, 1851, 1859, 1879, 1895, 1939, 1951, 1959, 2091, 2111, 2139, 2219, 2259, 2275, 2351, 2355, 2411, 2439

Conjecture 1 (Converse of Theorem 1). All k-hyperperfect numbers for odd $k>1$ are of the form given in Theorem 1.

If n is a k-hyperperfect number for even $k>1$ then clearly n is odd. All known k-hyperperfect numbers for odd $k>1$ are odd. If Conjecture 1 holds, then all k-hyperperfect numbers for $k>1$ are odd.

Herman te Riele [1981] noted that the six hyperperfect numbers for odd k known at that time [Minoli, 1980] were all of a form equivalent to that in Theorem 1.

Case 2: even values of *k*>1

Theorem 2. If p and q are distinct odd primes such that $k(p+q)=pq-1$ for some integer k, then $n=pq$ is k-

hyperperfect. Equivalently, $q=(kp+1)/(p-k)$.

Again we omit the proof.

There are some limitations on the values of k, p, and q that satisfy Theorem 2: (a) $k<p<2k<q$; and (b) except for $k=2$ (where $p=3$, $q=7$), p and q are congruent modulo 12, and k is a multiple of 6.

Table 4 gives some values of p, q, and k that satisfy Theorem 2. More values of p are given in sequence A034913, and values of p and q combined, in order, are contained in sequence A034914.

Theorem 3. Suppose $k>0$ and $p=k+1$ is prime. If $q=p^i-p+1$ is prime for some $i>1$ then $n=p^{i-1}q$ is k-hyperperfect.

Note that when $k=1$ and $p=2$ the theorem gives the familiar perfect numbers. Table 5 lists some examples of this theorem. Sequence A034915 gives the values of q in order.

For convenience, we will say hyperperfect numbers produced by Theorems 1, 2 and 3 are of *forms* 1, 2 and 3, respectively. Minoli [1980] gave a different (broader) sufficient condition for a number to be hyperperfect, which is also necessary for hyperperfect numbers of the form p^iq and does not depend on the parity of k.

For even $k>1$, there are 2105 k- hyperperfect numbers less than 10^{11}. The smallest of these is 21, which is 2-hyperperfect. The largest is 99671702281=107693*925517, which is 6468-hyperperfect. The largest even value of k represented is 156102, where 97885007917 = 293147*333911 is 156102-hyperperfect. Of these 2105 hyperperfect numbers, 2001 are of form 2 only, 17 are of form 3 only, 68 are of both forms, and 19 are of neither form. The known hyperperfect numbers that don't fit these forms all have three distinct prime factors. Thus all known hyperperfect numbers of the form p^iq are of forms 1, 2 or 3. The largest hyperperfect number less than 10^{11} of form 3 is also of form 2: 94860412321 = 4561*20798161 = pq; k=4560.

Table 6 gives the hyperperfect numbers less than 10^{11} that are of form 3 but not of form 2:

Table 6.

n	***k***	**factorization of *n***	**form of *q***

51886178401	138	139^2 2685481	139^3-139+1

For even values of *k* for which *k*-hyperperfect numbers exist, it is more common for there to be *k*-hyperperfect numbers when *k* is a multiple of 6 (form 2). For the 1852 even values of *k* having a *k*-hyperperfect number less than 10^{11}, all are multiples of 6 except for *k* = 2, 4, 10, 40, 100, 140, and 190. The first five of these cases have *k*+1 prime, and thus are hyperperfect numbers of form 3. For the other two cases, 157*2131*3343 is 140-hyperperfect and 229*1999*2551 is 190-hyperperfect.

We can apply Theorem 3 to find some large *k*-hyperperfect numbers when *k*+1=*p* is prime. For instance, referring to Table 2; there are no small (i.e. < 10^{11}) *k*-hyperperfect numbers for *k*=16, 22, 28, 36, 42, 46, etc - cases in which *k*+1 is prime. (There are other small values such as *k*=8, in which no 8-hyperperfect numbers are known.) We only have to check to see if $q=p^i-p+1$ is prime for some $i>1$ - if so then $p^{i-1}q$ is hyperperfect by Theorem 3. Table 7 shows the large hyperperfect numbers were found for *k*<=100, *k*+1=*p* prime, and *i*<=500:

Table 7.

Table 7 fills in some of the values for $k<=100$ in Table 2 for which there are no hyperperfect numbers $< 10^{11}$. A method was given by te Riele [1981] for generating hyperperfect numbers with three or more factors. He also gave hyperperfect numbers for $k = 42$, 72, and 96. A computation using this method (except not requiring $p=k+1$) for $p<2^{16}$, $q<r< 2^{31}$ did not reveal any additional hyperperfect numbers for $k<=100$.

A corollary of the prime number theorem is that the probability that a given integer x is prime is approximately $1/ln(x)$. Considering numbers of form 3, the probability that q is prime is approximately $1/ln(p^i)$. Since the sum of this quantity for i from 2 to infinity diverges, we expect an infinite number of k-hyperperfect numbers when $k+1$ is prime.

4. More than two primes

Nineteen of the hyperperfect numbers less than 10^{11} have three distinct prime factors (the first prime factor may be to a power greater than one) and none of them have more than three distinct factors. For even values of k, seventeen examples are of the form p^iq , for $i>1$, $p<q$, whereas 2069 of the examples are of the form pq, and two are of the form p^iqr . Table 8 gives hyperperfect numbers less than 10^{11} with more than two distinct prime factors:

A search was made for hyperperfect numbers of the form *pqr* using the method of te Riele [1981], except not requiring that $p=k+1$ (as he did for practical reasons). This search was restricted to $k <= 10{,}000$ and $p-k <= 1000$. An additional 346 hyperperfect numbers of the form $n=pqr$, $n>10^{11}$ were found. The largest value of k was 9930, for which 10009*1258219*125066187236071 is 9330-hyperperfect. Table 9 lists the ones found for $k <= 1000$.

Herman te Riele constructed eleven hyperperfect numbers with three distinct prime factors and one with four distinct prime factors. In his examples with three prime factors, he set $p=k+1$ for practical reasons; but that restriction is not necessary. This survey found sixteen additional hyperperfect numbers less than 10^{11} with three prime factors. The numbers that te Riele constructed that are less than 10^{11} are noted above. Table 10 lists hyperperfect numbers (for even k) with a prime factor to higher than first power:

The method of te Riele can not yield k-hyperperfect numbers of the form pqr for odd k. In that construction, n/p is even except when k=1 and p=2, so n/p cannot be factored into odd primes q and r.

Let us examine some small values of k. For k=2 all five examples are of form 3, as are both examples for k=4 and three of the four examples for k=6, the example for k=10, and others. The examples that are not of form 2 or form 3 can be constructed by the method of te Riele. Table 11 gives some examples with small k, which tend to be of form 3:

Table 11.

5. Remarks about general values of *k*

For 204 values of *k*, there are two or more *k*-hyperperfect numbers less than 10^{11}. Values of *k* with more than three examples are shown in table 13:

Table 13.

k	#	terms (sequence)

In view of Theorem 3, there should be *k*-hyperperfect numbers whenever *k*+1 is prime. When *k* is even and *k*+1 is composite the situation is less clear. For a value of *k* that is a multiple of 6, Theorem 2 provides only a finite number of possible *k*-hyperperfect numbers. The search up to 10^{11} revealed hyperperfect numbers for some of these values of *k*, but Theorem 2 fails to provide any more examples. Therefore there are even values of *k* for which (a) there are no *k*-hyperperfect numbers less than 10^{11}, (b) Theorem 2 fails to provide any examples, and (c) Theorem 3 does not apply. However, there could be hyperperfect numbers larger than 10^{11} of different forms for these even values of *k*. For example, 157*2131*3343 is 140-hyperperfect and 229*1999*2551 is 190-hyperperfect.

Daniel Minoli and Robert Bear [Guy, section B2] conjectured that there are *k*-hyperperfect numbers for every *k*. The data presented here can be taken as evidence that this conjecture is false. The most compelling reason is that the data suggests that the converse of Theorem 1 (Conjecture 1) is true, which would mean that there are odd values of *k* for which there are no *k*-hyperperfect numbers. Furthermore, as noted before, te Riele's construction (with three or more prime factors) is inapplicable for odd *k*.

For even values of *k* the situation is less clear. There are even values of *k* for which no *k*-hyperperfect number is known. If *k*+1 is prime then Theorem 3 should eventually produce a *k*-hyperperfect number. If *k* is a multiple of 6 then theorem 2 provides only a finite number of possibilities. Otherwise there is a chance that the method of te Riele will generate an example. However this chance seems small, and hyperperfect numbers constructed this way are rare. Considering the foregoing, the following conjecture is offered:

Conjecture 2. There are even values of k for which there are no k-hyperperfect numbers.

6. Conclusions

For odd values of $k>1$ we have given a construction which produces k-hyperperfect number, and we conjecture that all such hyperperfect numbers are of this form (for odd $k>1$).

For even values of k, we have exhibited two sufficient conditions that result in k-hyperperfect numbers. All known hyperperfect numbers with exactly two distinct prime factors are one of these two forms, but hyperperfect numbers with more than two distinct prime factors exist which are not of these forms. Some of these numbers were also constructed by te Riele.

We have given some evidence arguing against the conjecture published by Minoli and Bear that k-hyperperfect numbers exist for all $k>0$.

A final note: Minoli [1980] gave a list of the hyperperfect numbers less than 1,500,000 and stated that the computation took over ten hours of time on a PDP 11/70. This author's program searched the same range in under six seconds on a 300 MHz Pentium-II general-purpose electronic computer. Searching up to 10^{11} required several overnight runs, however.

Abstract

We give a closed form, a generating function, and an asymptotic estimate for the sequence $(z_n)_{n\geq 1} = 1, 0, 3, 8, 135, 1164, 21035, \ldots$ *that gives the total multiplicity of the eigenvalue* 0 *in the set of* n^{n-2} *tree incidence matrices of size* n.

1. Introduction.

By a classical result in graph theory, the number of labeled trees[1] on $n \geq 1$ vertices is n^{n-2}. We endow the set $\mathcal{T}_n$ of labeled trees on $n \geq 1$ vertices with uniform probability, giving weight n^{2-n} to each tree.

Each tree in $\mathcal{T}_n$ comes with its incidence matrix, the $n \times n$ symmetric matrix with entry ij equal to 1 if there is an edge between vertices i and j and to 0 otherwise. Each such matrix has n (real) eigenvalues, which by definition form the spectrum of the corresponding tree. This leads in turn to $n\, n^{n-2} = n^{n-1}$ eigenvalues counted with multiplicity for $\mathcal{T}_n$ as a whole. In the sequel, we will concentrate on the multiplicity of the eigenvalue 0. Let $Z(T)$ be the multiplicity of the eigenvalue 0 in the spectrum of the incidence matrix of the tree T, i.e. the dimension of the kernel. For each $n \geq 1$, the restriction Z_n of Z to $\mathcal{T}_n$ is a random

[1] Precise definitions for this and the following terms can be found in Section 2.

variable. We set $z_n = \sum_{T\in\mathcal{T}_n} Z_n(T)$. The expectation of $Z_n(T)$ is $\mathbb{E}(Z_n) = z_n/n^{n-2}$.

To illustrate these definitions, we give an explicit enumeration of $z_1, \cdots, z_4$ in Appendix A.

Our aim is to prove :

Theorem 1. *Let z_n be the total multiplicity of the eigenvalue 0 in the spectra of the n^{n-2} labeled trees on n vertices. Then :*

i) Closed form :

$$\begin{aligned} z_n &= n^{n-1} - 2\sum_{2\le m\le n} (-1)^m n^{n-m} m^{m-2} \binom{n-1}{m-1} \\ \frac{z_n}{n^{n-2}} \equiv \mathbb{E}(Z_n) &= n\left(1 - 2\sum_{2\le m\le n} \frac{(-1)^m}{m}\left(\frac{m}{n}\right)^m \binom{n}{m}\right). \end{aligned}$$

ii) Formal power series identity :

$$x^2 + 2x - xe^x = \sum_{n\ge 1} \frac{z_n}{n!}\left(xe^x e^{-xe^x}\right)^n .$$

Corollary 2. *For large n, $\mathbb{E}(Z_n)$ has an asymptotic expansion in powers of $1/n$ whose first two terms are*

$$\mathbb{E}(Z_n) = (2x_* - 1)n + \frac{x_*^2(x_*+2)}{(x_*+1)^3} + O(1/n)\,,$$

where $x_* = 0.567143290409783872999\cdots$ is the unique real root of $x = e^{-x}$. In particular, the average fraction of the spectrum occupied by the eigenvalue 0 in a large random tree is asymptotic to $2x_* - 1 = 0.134286508195677459999\cdots$.

Remark 3. We do not try to show here that the fluctuations in random trees become small when the number of vertices is large. However, it is expected that $\mathbb{E}(Z_n^2) - \mathbb{E}(Z_n)^2$ grows only linearly with the number of vertices, so that in an appropriate sense the fraction of the spectrum occupied by the eigenvalue 0 in an infinite random tree is $2x_* - 1$ with probability 1.

Remark 4. With the explicit formula above, it is easy to list the first terms in the sequence $(z_n)_{n\ge 1}$, which are

$$1, 0, 3, 8, 135, 1164, 21035, 322832, 7040943, 153153620, 4048737099, \cdots$$

To prove part i) of Theorem 1 we establish a few preparatory lemmas of independent interest. Then we prove ii) using Lagrange inversion and obtain Corollary 2 by the steepest descent method.

There is an application of Z_n to random graph theory — see Remark 22.

2. Definitions.

Even if ultimately we are interested only in trees, we shall need more general graphs (for instance, forests) in the proofs.

Definition 5. A *simple graph* G is a pair (V, E) where V is a finite set called the set of *vertices* and E is a subset of $V^{(2)} \equiv \{\,\{x, y\},\ x \in V,\ y \in V,\ x \neq y\}$ called the set of *edges*.

Remark 6. The adjective *simple* refers to the fact that there is at most *one* edge between two vertices and that edges are pairs of *distinct* vertices. From now on we use *graph* for *simple graph*.

Definition 7. If V is empty, then we say that the graph G is *empty*. The vertices adjacent to a given vertex x are called the *neighbors* of x. The number of neighbors of a vertex x is called the *degree* of x. A *leaf* of G is a vertex of degree 1. Two edges of G with a common vertex are called *adjacent edges*

Definition 8. A *labeled* graph on $n \geq 1$ vertices is a graph with vertex set $[n] = \{1, \cdots, n\}$.

Remark 9. If the graph G has $|V| = n \geq 1$ vertices[2], any bijection between V and $[n]$ defines a labeled graph. The incidence matrices for different bijections differ only by a permutation of the rows and columns. In particular the eigenvalues are independent of the bijection.

Definition 10. The *spectrum* of a graph is the set of eigenvalues (counted with multiplicity) of any of the associated incidence matrices. By convention, the spectrum of the empty graph is empty.

Definition 11. A *subgraph* of a graph $G = (V, E)$ is a graph (W, F) such that $W \subset V$ and $F \subset E$. An *induced subgraph* of G is a graph (W, F) such that $W \subset V$ and $F = E \cap W^{(2)}$.

[2]For any finite set S , $|S|$ is the number of elements in S.

Definition 12. We say that two vertices x and $x' \in V$ are in the *same component* of G if there is a sequence $x = x_1, \cdots, x_n = x'$ in V such that adjacent terms in the sequence are adjacent in G (taking $n = 1$ shows that luckily x and x are in the same component). This gives a partition of V. Each component defines an induced subgraph of G which is called a *connected component* of G. Then G can be thought of as the disjoint union of its connected components. We say that G is *connected* if it has only one connected component.

Definition 13. A *polygon* in a graph G is a sequence $x_0, x_1, \cdots, x_n$, $n \geq 3$ of vertices such that adjacent terms in the sequence are adjacent in G, $x_0 = x_n$ and $x_1, \cdots, x_n$ are distinct.

Definition 14. A *forest* is a graph without polygons. A *tree* is a non-empty connected forest.

Remark 15. Clearly a subgraph of a forest is a forest. The connected components of a nonempty forest are trees. One shows easily that that a tree with $n \geq 2$ vertices has at least two leaves. Then a simple induction shows that a tree is exactly a connected graph for which the number of vertices is 1 plus the number of edges. A classical theorem of Cayley states that there are n^{n-2} labeled trees on n vertices (see for instance Proposition 5.3.2 in [3]).

3. Two preparatory lemmas.

The first lemma is a characterization of the dimension of the kernel of incidence matrices viewed as a function on forests.

Lemma 16. *The function Z which associates to any forest the multiplicity of the eigenvalue 0 in its spectrum is characterized by the following properties :*

i) The function Z takes the value 0 on $\emptyset$, the empty forest.

ii) The function Z takes the value 1 on $\bullet$, the forest with one vertex.

iii) The function Z is additive on disjoint components, i.e. if the forest F is the union of two disjoint forests F_1 and F_2 then $Z(F) = Z(F_1) + Z(F_2)$

iv) The function Z is invariant under "leaf removal", i.e. if x is a leaf of F, y is its (unique) neighbor, $V' = V \backslash \{x, y\}$, and F' is the subforest of F induced by V' then $Z(F) = Z(F')$.

Remark 17. That the function Z satisfies properties i)–iv) was no doubt known decades ago (see for instance Section 8.1, Hückels theory,

in [1]). We give a proof, because in the sequel we want to emphasize and use the simple fact that these properties characterize the function Z.

Proof of Lemma 16. First, we show that the function Z has properties i)–iv). In fact, this is true for general graphs (not only forests). Properties i) and ii) follow from the definition of Z, property iii) follows from the fact that the incidence matrix can be put into block diagonal form, each block corresponding to a connected component. Property iv) is only slightly more complicated. With an appropriate labeling of the vertices, the incidence matrix $\mathbf{M}$ of F can be decomposed as

$$\mathbf{M} = \begin{pmatrix} 0 & 1 & \mathbf{0} \\ 1 & 0 & \mathbf{N} \\ \mathbf{0} & {}^t\mathbf{N} & \mathbf{M}' \end{pmatrix}$$

where the first row and column are indexed by the leaf x, the second row and column are indexed by its neighbor y, $\mathbf{N}$ describes the edges between this neighbor and V', and $\mathbf{M}'$ is the incidence matrix for V'. Then $\mathbf{v} = {}^t(v_1, v_2, \mathbf{v}')$ is in the kernel of $\mathbf{M}$ if and only if

$$\begin{aligned} v_2 &= 0 \\ v_1 &= -\mathbf{N}\mathbf{v}' \\ \mathbf{M}'\mathbf{v}' &= -{}^t\mathbf{N}v_2. \end{aligned}$$

So $v_2 = 0$ which from the third equation gives $\mathbf{M}'\mathbf{v}' = \mathbf{0}$, implying that $\mathbf{v}'$ is in the kernel of $\mathbf{M}'$, and then the second equation just gives v_1 the appropriate value. So the kernels of $\mathbf{M}$ and $\mathbf{M}'$ have the same dimension. This proves iv).

Now, any tree with more than 1 vertex has leaves, so leaf removal as defined in iv) allows one to reduce the forest F to a (possibly empty) family of isolated vertices (all connected components have only one vertex). Hence there is at most one function, namely Z, that can satisfy properties i)–iv). ∎

Remark 18. Leaf removal and additivity give an efficient algorithm for computing the multiplicity of the eigenvalue 0 for a given forest, especially when this forest is given as a drawing.

The next lemma gives an impractical but theoretically useful formula for the function Z.

Lemma 19. *Let L be the function on forests defined by:*
i') The function L takes the value 0 on $\emptyset$, the empty forest.
ii') The function L takes the value 1 on $\bullet$, the forest with one vertex.
iii') The function L takes the value 0 on disconnected forests.

iv') The function L takes the value $2(-1)^{n-1}$ on trees with $n \geq 2$ vertices.

Then, for any forest F

$$Z(F) = \sum_{F' \subset F} L(F') = \sum_{T' \subset F} L(T')$$

where the first sum is over induced subforests of F, and the second over induced subtrees of F.

Remark 20. For a given forest, there is a much nicer formula, directly connected to the geometry of the forest (again, see for instance Section 8.1, Hückels theory, in [1]). In fact, let $Q(F)$ be the maximum among the cardinalities of sets of pairwise non-adjacent edges in F, and $N(F)$ be the number of vertices in F. Then $Z(F) = N(F) - 2Q(F)$. It is easy to show that $N(F) - 2Q(F)$ satisfies properties i)–iv) of Lemma 16. In particular, a possible way to maximize the number of non-adjacent edges in F in case iv) is to do so on F' and add the edge $\{x, y\}$. This explicit formula allows us to restate our theorems in terms of the random variable Q_n, the restriction of Q to $\mathcal{T}_n$. For instance, in a large random tree on n vertices, one can find about $(1-x_*)n$ pairwise non-adjacent edges. Note that $1 - x_* = 0.4328567095902161270000\cdots$ is not much smaller than 0.5 (the upper bound for $Q(T)/N(T)$ for a given tree because $Z(T) = N(T) - 2Q(T)$ is always nonnegative).

Proof of Lemma 19. Our strategy is to use the characterization of Z in Lemma 16. First, we observe that the second equality is a trivial consequence of i') and iii'). We define a new function Z' on the set of forests by

$$Z'(F) \equiv \sum_{T' \subset F} L(T')$$

(where the sum is over induced subtrees of F) and show that Z' satisfies properties i)–iv) of Lemma 16.

As the empty forest has no non-empty induced subtree i') implies i).

In the same vein, the forest with one vertex has only one non-empty induced subtree, namely itself, so ii') implies ii).

If the forest F is the union of two disjoint forests F_1 and F_2, an induced subtree of F is either an induced subtree of F_1 or an induced subtree of F_2, and the sum defining $Z'(F)$ splits as $Z'(F_1) + Z'(F_2)$, showing that Z' satisfies property iii).

Now, if x is a leaf of F and y its neighbor, we define $V' = V \backslash \{x, y\}$, $V'' = \{x, y\}$ and consider F' and F'', the subforests of F induced by V' and V'' respectively. We split the sum defining $Z'(F)$ into three pieces. The first is over the induced subtrees of F'. This is just the

sum defining $Z'(F')$. The second is over the induced subtrees of F'', which is a tree on two vertices. Its subtrees are itself, with weight $L(F'') = 2(-1)^{2-1} = -2$, and two trees with one vertex, each with weight $L(\bullet) = 1$, so this second sum gives 0. The third sum is over induced subtrees that have vertices in both V' and V''. If this sum is not empty, every tree that appears in it has y as a vertex (by connectivity) and has at least two vertices (because the tree consisting of y alone has already been counted). Then we can group these trees in pairs, a tree containing x being paired with the same tree but with x and the edge $\{x, y\}$ deleted. The function L takes opposite values on the two members of a pair, so the third sum contributes 0. Hence Z' satisfies property iv). So $Z'(F) = Z'(F')$. ∎

Remark 21. These two lemmas have an obvious extension to bicolored forests. If we use black and white as the colors, and count the zero eigenvectors having value zero on white vertices, we only need to replace ii) in Lemma 16 by

ii) The function Z takes the value 1 *on* •*, the forest with one vertex colored in black and* 0 *on* ∘*, the forest with one vertex colored in white,*

and ii') and iii') in Lemma 19 by

ii') The function L takes the value 1 *on* •*, the forest with one vertex colored in black and* 0 *on* ∘*, the forest with one vertex colored in white,*

iii') The function L takes the value $(-1)^{n-1}$ on trees with $n \geq 2$ vertices.

The proofs remain the same.

Remark 22. The formula

$$Z(F) = \sum_{F' \subset F} L(F')$$

can be inverted using inclusion-exclusion to give

$$L(F) = \sum_{F' \subset F} (-1)^{|V(F)|-|V(F')|} Z(F').$$

This identity has an application in random graph theory [2], which led to our interest in Lemma 19.

4. Main proofs.

Proof of Theorem 1. By Lemma 16

$$z_n \equiv \sum_{T \in \mathcal{T}_n} Z_n(T) = \sum_{m=1}^{n} \sum_{T \in \mathcal{T}_n} \sum_{T' \in \mathcal{T}_m}^{T' \subset T} L(T').$$

As the function L depends only on the number of vertices, for fixed m the double sum $\sum_{T\in\mathcal{T}_n}\sum_{T'\in\mathcal{T}_m}^{T'\subset T}$ is simply a multiplicity. We count this multiplicity as follows : we remove from T the edges of T', so we are left with m trees, each with a special vertex, the one belonging to T'. This is what is called a planted forest (or rooted forest) with n vertices and m trees. The number of such objects is $m\binom{n}{m}n^{n-m-1}$ (see for instance Proposition 5.3.2 in [3]). Conversely, starting from such a planted forest with m trees (each with a special vertex) and n vertices, we can build a tree on the special vertices in m^{m-2} ways. So

$$\sum_{T\in\mathcal{T}_n}\sum_{T'\in\mathcal{T}_m}^{T'\subset T} 1 = m^{m-1}\binom{n}{m}n^{n-m-1}.$$

Hence summation over m gives

$$z_n = n^{n-1} - 2\sum_{2\le m\le n}(-1)^m n^{n-m-1}m^{m-1}\binom{n}{m}.$$

Simple rearrangements lead to the two equivalent formulæ in i), the first one making clear that z_n is an integer.

To obtain the generating function in ii), we need a mild extension of the Lagrange inversion formula (see for instance Section 5.4 in [3]), which states that if $f(x)$ is a formal power series in x beginning $f(x) = x + O(x^2)$ and $g(x)$ is an arbitrary formal power series in x, then

$$\left(g\circ f^{-1}\right)(t) = g(0) + \sum_{n\ge1}\frac{1}{n}\left[\frac{x^n g'(x)}{f(x)^n}\right]_{n-1} t^n\,,$$

where $[h(v)]_k$ is by definition the k^{th} coefficient of the formal power series $h(v)$.

As an immediate application, we see that if $t = xe^x$ then

$$x = \sum_{m\ge1}(-m)^{m-1}\frac{t^m}{m!}$$

and

$$-x - x^2/2 = \sum_{m\ge1}(-m)^{m-2}\frac{t^m}{m!}.$$

Now we introduce $y = te^{-t}$ and define a sequence $z'_n, n\ge1$, by

$$x^2 + 2x - xe^x = \sum_{n\ge1} z'_n\frac{y^n}{n!},$$

but instead of directly applying the Lagrange inversion formula to $y = xe^x e^{-xe^x}$, we first substitute the t-expansion (already obtained

by Lagrange inversion) on the left-hand side, which yields

$$-2\sum_{m\geq 1}(-m)^{m-2}\frac{t^m}{m!}-t,$$

and then apply Lagrange inversion with $y=te^{-t}$. The result is

$$\frac{z_n'}{n!}=\frac{1}{n}\left[e^{nt}\left(1-2\sum_{m\geq 2}\frac{(-m)^{m-2}}{(m-1)!}t^{m-1}\right)\right]_{n-1}.$$

Straightforward expansion of this formula shows that $z_n'=z_n$, and this establishes the generating function representation in ii). ∎

Remark 23. The derivation of ii) is quite artificial. It turns out that random graph theory gives a natural proof [2] using the formula mentioned in Remark 22.

Proof of Corollary 2. This time we use Lagrange inversion with $y=xe^xe^{-xe^x}$, in a contour integral representation[3]. So

$$\frac{z_n}{n!}=\frac{1}{n}\oint\frac{dx}{(xe^xe^{-xe^x})^n}(1+x)(2-e^x),$$

where the contour is a small anticlockwise-oriented circle around the origin. For large n we use the steepest descent method to obtain the asymptotic expansion of z_n. As $\frac{d}{dx}xe^xe^{-xe^x}=(1+x)(1-xe^x)e^xe^{-xe^x}$, the saddle points of $xe^xe^{-xe^x}$ are $x=-1$ and the solutions to $x=e^{-x}$. This equation has a unique real root, x_*, which is positive. Numerically, $x_*=0.5671432904097838729999\cdots$. On the other hand, $x=e^{-x}$ has an infinite number of complex solutions, in complex conjugate pairs. Asymptotically, the imaginary parts of these zeros are evenly spaced by about 2π, while their real parts are negative and grow logarithmically in absolute value. Consideration of the landscape produced by the modulus of the function $xe^xe^{-xe^x}$ shows that the small circle around the origin can be deformed to give the union of two steepest descent curves, one passing through $x=-1$ and the other through $x=x_*$. These two curves are asymptotic to the two lines $y=\pm\pi$ at $x\to+\infty$. Hence, despite the fact that the value of $xe^xe^{-xe^x}$ is the same, namely $1/e$, at all the complex saddle points and at x_*, the complex saddle points do not contribute to the asymptotic expansion of z_n at large n. Moreover, the point $x=-1$ only gives subdominant contributions because $-e^{-1}e^{e^{-1}}$ is larger than $1/e$ in absolute value. So we concentrate on the asymptotic

[3]We include the factor $\frac{1}{2i\pi}$ in the symbol $\oint$.

expansion around x_*. As

$$\log xe^x e^{-xe^x} = -1 - \frac{(x_*+1)}{2x_*}(x-x_*)^2 + O((x-x_*)^3)$$

we infer that

$$e^{-n}\sqrt{2\pi n}\oint \frac{dx}{(xe^x e^{-xe^x})^n}(1+x)(2-e^x)$$

has an asymptotic expansion in powers of $1/n$. By use of Stirling's formula for $n!$ we conclude that $\mathbb{E}(Z_n) = z_n/n^{n-2}$ has an asymptotic expansion in powers of $1/n$. The first two terms are obtained by brute force. ∎

Appendix A. Examples of direct multiplicity counting.

This appendix enumerates the multiplicities of 0 in the spectrum of trees with $n = 1, 2, 3$ or 4 vertices.

Example 24. For $n = 1$ there is only one tree,  , and one way to label it, giving $1 = 1^{1-2}$ tree on one vertex. The incidence matrix is (0), so the eigenvalue 0 occurs with multiplicity $z_1 = 1$.

Example 25. For $n = 2$ there is only one tree,  , and one way to label it, again giving $1 = 2^{2-2}$ tree on two vertices. The incidence matrix is

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

so the eigenvalue 0 occurs with multiplicity $z_2 = 0$.

Example 26. For $n = 3$ there is only one tree,  , and three ways to label it, giving a total of $3 = 3^{3-2}$ trees on three vertices. Up to permutation of rows and columns, the incidence matrix for each of these three labeled trees is

$$\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix},$$

which has zero as an eigenvalue with multiplicity 1 (a corresponding eigenvector is ${}^t(1, 0, -1)$), so there is a total of 3×1 zero eigenvalues, and $z_3 = 3$

Example 27. For $n = 4$ there are two trees, (12 ways to label it), and (4 ways to label it), giving a total of $12 + 4 = 16 = 4^{4-2}$

trees on three vertices. Up to permutation of rows and columns, the two incidence matrices are

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}.$$

The first does not have 0 as an eigenvalue, whereas the second has zero as an eigenvalue with multiplicity 2 (corresponding eigenvectors are for instance ${}^t(1,0,-1,0)$ and ${}^t(1,0,0,-1)$), so there is a total of $12 \times 0 + 4 \times 2$ zero eigenvalues, and $z_4 = 8$.

Abstract: The purpose of this paper is to identify, as far as possible, those sequences in the Encyclopedia of Integer Sequences which count orbits of an infinite permutation group acting on *n*-sets or *n*-tuples of elements of the permutation domain. The paper also provides an introduction to the properties of such sequences and their relations with combinatorial enumeration problems.

Contents

1. Introduction

A permutation group on an infinite set is *oligomorphic* if the number of orbits on ordered *n*-tuples is finite for all positive integers *n*. Here a permutation *g* of a set *X* acts on the set X^n of all *n*-tuples of

elements of X by the rule

$$(x_1, ..., x_n)g = (x_1g, ..., x_ng).$$

Many important sequences of integers can be realised as sequences counting orbits of an oligomorphic group on n-tuples or n-sets. The purpose of this paper is to document all examples known to the author of such sequences occurring in the Encyclopedia of Integer Sequences. Since this list of examples is unlikely ever to be complete, it is planned to update it from time to time. Please email suggested additions to the author at the address above.

The paper also includes some general theory of oligomorphic permutation groups and their relation to combinatorial enumeration. Further details can be found in references [3] and [5].

Many familiar sequences will be found here (Fibonacci numbers, partitions, graphs, trees, binomial coefficients, powers, ...). It is the author's contention that the occurrence of a sequence as the U- or L-sequence of an oligomorphic group gives it extra interest. Also, if the U-sequence of a group is interesting, then so is the L-sequence, and *vice versa* - so the blanks in the tables are worth investigating!

The tables also provide data on which to base conjectures about the behavious of U- and L-sequences of oligomorphic permutation groups.

Note that the examples and constructions reported here are closely related to species (see [1]); however, species are more general, and some of the known restrictions for U-sequences of oligomorphic groups (see Section 2.4) do not apply to counting sequences for species. Cross-references will be given where appropriate.

2. Oligomorphic permutation groups

The concept of an oligomorphic permutation group was defined in the Introduction. From the definition, if G is an oligomorphic permutation group on a set X, then each of the following numbers is finite for each positive integer n:

- $f_n(G)$, the number of orbits of G on the set of n-element subsets of X;
- $F_n(G)$, the number of orbits of G on the set of ordered n-tuples of distinct elements of X;
- $F_n^*(G)$, the number of orbits of G on the set of all ordered n-tuples of elements of X.

By convention, we set $f_0(G) = F_0(G) = F_0^*(G) = 1$. We omit (G) if the group in question is clear.

In what follows, all permutation groups are taken to act on countable sets. This loses no generality: an argument based on the Downward Löwenheim-Skolem Theorem of first-order logic shows that, given

any oligomorphic permutation group G, there is an oligomorphic group acting on a countable set which realises the same numbers f_n, F_n, and F_n^* (see [3]).

2.1. Connection with logic

The third of these sequences arises naturally in connection with the notion of countable categoricity in first-order logic. Let T be a consistent complete theory in a first-order language.

We say that T is *countably categorical* if it has a unique countable model up to isomorphism.

An *n-type* over T is a set of formulae in n free variables $x_1, ..., x_n$ which is maximal with respect to being consistent with T. The n-type S is *realized* in a model M of T if there exist elements $a_1, ..., a_n$ in M such that the formulae in S are true when the as are substituted for the xs. (Note that the set of all formulae holding on a given tuple of elements in a model of T is a type.)

Now the theorem of Engeler, Ryll-Nardzewski, and Svenonius asserts the following.

> **Theorem.** Let T be a consistent complete theory in a first-order language. Then T is countably categorical if and only if it has only finitely many n-types for each positive integer n. If these conditions hold, and M is the countable model of T, then every type S is realised in M, and the set of tuples realising S is an orbit of the automorphism group of M.
>
> Conversely, let M be a countable structure over a first-order language, and suppose that the automorphism group of M is oligomorphic (as a permutation group on M). Then the first-order theory of M is countably categorical.

In view of this theorem, we apply the term "countably categorical" also to a countable structure whose automorphism group is oligomorphic.

We see that, if M is the countable model of a countably categorical theory T, then the number of n-types of T is equal to $F_n^*(G)$, where G is the automorphism group of M.

2.2. U- and L-sequences

Despite the preceding section, this paper will concentrate on the sequences $(f_n(G))$ and $(F_n(G))$, for reasons which will appear. A sequence of positive integers will be called an *U-sequence* or an *L-sequence* if it is realised as the orbit-counting sequence $(f_n(G))$ or $(F_n(G))$ respectively, for some oligomorphic group G. (The letters U and L stand for "unlabeled" and "labeled". The reason for this will be explained below.) The primary aim of this project is to annotate the Encyclopedia of Integer Sequences with information about which of its entries are U-sequences or L-sequences. The first reason

for neglecting (F_n^*) is that its values can be determined from those of (F_n by the following formula, in which $S(n,k)$ is the *Stirling number* of the second kind (the number of partitions of a n-set into k parts):

$$F_n^* = Sum_k\, S(n,k)F_k.$$

In the terminology of Bernstein and Sloane [2], the starred sequence is the *Stirling transform* of the unstarred: F^*=**STIRLING**(F). (See also the section on transformations in the On-Line Encyclopedia.)

We will see later that the Stirling transform of an L-sequence is also an L-sequence. So the class of realisable sequences would not be enlarged by including the starred sequences.

A related observation we will also see later is that, for many groups G, there exists a group G^* whose U-sequence is the L-sequence of G.

2.3. Two important examples

We conclude this section with two important examples of oligomorphic groups:

- S, the symmetric group on an infinite set. Clearly $f_n(S)=F_n(S)$: this all-1 sequence is number A000012 in the Encyclopedia. Hence

  $$f_n^*(S) = Sum_k\, S(n,k) = B(n),$$

  the *Bell number*(the total number of partitions of an n-set), sequence A000110. As noted, this will show that the Bell numbers form an L-sequence.
- A, the group of all order-preserving permutations of the rational numbers. Since every n-set can be carried into any other, but only in the same order, we have $f_n(A)=1$, $F_n(A)=n!$. The latter shows that the factorial numbers (sequence A000142) form an L-sequence. Also, $F_n^*(A)$ is the number of n-element *preorders*, or sets with a equivalence relation whose equivalence classes are totally ordered (sequence A000670). So this is an L-sequence. (This sequence is referred to as "preferential arrangements" in the Encyclopedia, and as "(labeled) ballots" in [1].)

2.4. Some restrictions

A number of restrictions on U- and L-sequences are known. Most concern the rate of growth of the sequence. We are very far from having a necessary and sufficient condition!

U-sequences have been studied more than L-sequences. The following results are for the most part due to Dugald Macpherson in [8] and other papers, and are discussed further in the references already cited.

- A U-sequence is non-decreasing. (There are some restrictions known on sequences with consecutive terms equal.)
- A U-sequence which grows faster than polynomially must grow at least at a fractional exponential rate (similar to the partition function).
- The U-sequence of a primitive permutation group (one preserving no non-trivial equivalence relation) is either the all-1 sequence (number A000012) or grows at least exponentially.

Macpherson also has some results about faster growth rate, related to model-theoretic properties such as stability and the strict order property.

L-sequences are also non-decreasing (though this is much easier to see); in fact, consecutive terms of an L-sequence are equal only if they are both 1. Francesca Merola [10] has recently strengthened Macpherson's exponential growth result by showing that the L-sequence of a primitive but not highly homogeneous group grows at least as fast as $c^n n!$, for some constant $c>1$.

3. Cycle index

3.1. Generating functions

We represent a U-sequence (f_n) by its *ordinary generating function* (for short, o.g.f.)

$$f(x) = Sum\ f_n x^n,$$

and an L-sequence (F_n) by its *exponential generating function* (for short, e.g.f.)

$$F(x) = Sum\ F_n x^n/n!.$$

If necessary, we specify the group by writing these power series as $f_G(x)$ and $F_G(x)$.

3.2. Cycle index

Both these power series are specialisations of a power series in infinitely many variables, the *modified cycle index*, which we now define in three stages.

If g is a permutation on n points, the *cycle index* of g is defined to be the monomial

$$z(g) = {s_1}^{c_1} \ldots {s_n}^{c_n}$$

in indeterminates s_1, ..., s_n, where c_i is the number of i-cycles in the cycle decomposition of g.

Now let G be a permutation group on a set of size n. The *cycle index* $Z(G)$ of G is obtained simply by summing the cycle indices of its elements and dividing by the order of the group G.

Finally, let G be an oligomorphic permutation group acting on the (usually infinite) set X. The *modified cycle index* $\mathbf{Z}(G)$ is obtained as follows: choose a set of representatives of the orbits of G on finite subsets of X. For each such finite set, consider the group of permutations induced on it by its setwise stabilizer in G, and calculate the cycle index of this finite permutation group. Then add all these cycle indices. (This infinite sum is permissible since any given monomial only arises from sets of fixed finite cardinality n, and there are only finitely many orbit representatives on n-sets to consider since G is oligomorphic.) By convention, we take the term corresponding to the empty set to be 1. Thus $\mathbf{Z}(G)$ is a formal power series in the indeterminates s_1, s_2, ...

What is important for our purpose are the following facts:

- The o.g.f. of the U-sequence of G is obtained from $\mathbf{Z}(G)$ by the substitution
  - $s_1 := x$,
  - $s_i := 0$ for $i > 1$.
- The e.g.f. of the L-sequence of G is obtained from $\mathbf{Z}(G)$ by the substitution
  - $s_i := x^i$ for all i.

4. New groups from old

4.1. Direct product

Let G and H be permutation groups on sets X and Y respectively. The *direct product* $G \mathit{Times} H$ acts on the disjoint union $X \mathit{union} Y$ as follows: the ordered pair (g,h) acts on X as g and on Y as h. We have the following:

$$\mathbf{Z}(G \mathit{Times} H)=\mathbf{Z}(G)\mathbf{Z}(H).$$

This operation corresponds to the operation of *species product* of species (see [1]).

Thus the exponential generating function of the L-sequence for $G \mathit{Times} H$ is obtained by multiplying those for G and H; and similarly for the ordinary generating function of the U-sequence. The operations on sequences are **CONV** for the U-sequence and **EXPCONV** for the L-sequence.

In particular, the operation of forming the direct product with S replaces the U-sequence by its **PSUM** transform, whose terms are the partial sums of the original sequence; and replaces the L-sequence by its

BINOMIAL transform.

There is another action of the direct product. The *product action* is on *X Times Y*, where the pair (*g*,*h*) maps (*x*,*y*) to (*xg*,*yh*). Counting orbits in this action is much more difficult, and is not even solved for *S Times S*. (The n^{th} term in the U-sequence is A049311, the number of zero-one matrices with *n* ones and no zero rows or columns, up to row and column permutations; equivalently, bipartite graphs with *n* edges and no isolated vertices with a prescribed bipartite block.)

4.2. Wreath product

Again let *G* and *H* be permutation groups on sets *X* and *Y* respectively. The *wreath product G Wr H* is defined as follows, as a permutation group on *X Times Y*: it contains a *base group B*, the set of functions from *Y* to *G*, where the function *f* maps (*x*,*y*) to (*xf*(*y*),*y*); and a *top group T*, a group isomorphic to *H*, where the element *h* maps (*x*,*y*) to (*x*,*yh*). The wreath product of *G* and *H* is the (semi-direct) product of *B* and *T*.

The operation of wreath product corresponds to *species substitution* (or *partitional composition*) of species: see [1].

The L-sequence of *G Wr H* can be calculated from those of *G* and *H* by substitution:

$$F_{G\ Wr\ H}(x) = F_H(F_G(x)\text{-}1).$$

However, there is no formula for the L-sequence of *G Wr H* in terms of those of *G* and *H*. There is such a formula for the modified cycle index as follows:

$$\mathbf{Z}(G\ Wr\ H; s_1, s_2, \ldots) = \mathbf{Z}(H; \mathbf{Z}_1\text{-}1, \mathbf{Z}_2\text{-}1, \ldots),$$

where $\mathbf{Z}_i$ is obtained from $\mathbf{Z}(G)$ by substituting s_{ij} for s_j, for all *j*.

From this it follows that the e.g.f. for the U-sequence for *G Wr H* can be obtained from $\mathbf{Z}(H)$ by substituting $f_G(x^i)$-1 for s_i for all *i* (where f_G is the o.g.f. for the U-sequence of *G*).

In particular, we see that for each oligomorphic permutation group *H*, there is an operator (also denoted by *H*) on sequences, with the property that it maps the U-sequence of *G* to that of *G Wr H* for any oligomorphic group *G*. The set of all U-sequences of oligomorphic groups is closed under all these operators. The operators *S*, *A*, and *C* are the operators **EULER**, **INVERT**, and **CIK**. respectively. See [4] for further details.

Various formal identities hold for these products: for example,

- $A\ Wr\ (B\ Wr\ C) = (A\ Wr\ B)\ Wr\ C$,
- $A\ Wr\ (B\ Times\ C) = (A\ Wr\ B)\ Times\ (A\ Wr\ C)$.

Now we can explain why the sequence $(F_n^*(G))$ is an L-sequence - indeed, it is the L-sequence of the group $S\ Wr\ G$. Let S and G act on sets X and Y respectively, so that $S\ Wr\ G$ acts on $X\ Times\ Y$. Then there is a function from n-tuples of distinct elements of $X\ Times\ Y$ to arbitrary n-tuples of Y, mapping each ordered pair to its second element. Clearly this mapping preserves orbits. Moreover, since X is infinite, any n-tuple of elements of Y lies in the image of the mapping. So

$$F_n^*(G) = F_n(S\ Wr\ G).$$

Indeed, this example shows that the L-sequence of $G\ Wr\ S$ is the **STIRLING** transform of that of G. The substitution rule gives the well-known formula

$$F_{S\ Wr\ G}(x) = F_G(e^x-1).$$

The U- and L-sequences for $S\ Wr\ S$ are A000041 (partitions) and A000110 (Bell numbers) respectively.

If S_k denotes the finite symmetric group of degree k, then $S_k\ Wr\ S$ and $S\ Wr\ S_k$ have the same U-sequences, since the number of partitions with parts of size at most k is equal to the number of partitions with at most k parts. However, their L-sequences differ. For $k = 2$, they are A000085 (self-inverse permutations) and A000079 (powers of two, shifted right one place) respectively. Another interesting example is $S_2\ Wr\ A$, whose U-sequence is A000045 (Fibonacci numbers).

Two further special cases are notable. Let E denote the trivial group acting on a set with two elements. Then

- $G\ Wr\ E$ is isomorphic to $G\ Times\ G$, which we have already considered.
- $E\ Wr\ G$ is the group G with each orbit duplicated. For $G = S$, we obtain the U-sequence A002620 (quarter-squares), and L-sequence A000898. For $G = A$, the U-sequence is A000129 (Pell numbers), and the L-sequence is obtained by multiplying the n^{th} term by $n!$ (since all orderings of an n-set lie in different orbits): this is the operation **LISTTOLISTMULT**.

There is another action of the wreath product, the so-called *product action* on the set of functions from Y to X. This is not oligomorphic unless the top group is finite.

4.3. Stabilizer

Another operation on permutation groups consists of taking the stabilizer of a point. Let G be transitive

on X, and let H denote the subgroup consisting of elements of G fixing the point x of X, acting on the points different from x. Then the modified cycle index of H is obtained by differentiating that for G with respect to s_1. If G is not transitive, then this derivative is equal to the sum of the modified cycle indices of a set of orbit representatives.

The operation of taking the derivative corresponds to the *species derivative* for species (see [1]).

It follows (or is easily proved directly) that, if G is transitive, then the L-sequence for a point stabilizer is obtained from that of G by shifting the sequence one place left (deleting the initial 1). This is the operator **LEFT**.

The U-sequence of the stabilizer is not determined by that of G.

To summarise: The set of e.g.f.s of L-sequences is closed under multiplication, substitution, and (if the first term is 1) differentiation (or left shift). The set of o.g.f.s of U-sequences is closed under multiplication and under the sequence operator associated with any oligomorphic group (in particular, the **EULER** and **INVERT** operators).

4.4. Other constructions

This by no means exhausts the possible constructions, though in other cases it is not known how to calculate the L- and U-sequences.

If G is oligomorphic on X, then the permutation group induced by G on any of its orbits on n-sets, n-tuples, etc., for any n, is oligomorphic. For a specific example, let $G = S$, the infinite symmetric group, in its action on 2-sets. Any set of n 2-sets can be regarded as the edges of a graph, whose vertex set is the union of the n pairs (so that the graph has no isolated vertices). Two n-sets lie in the same orbit if and only if the graphs are isomorphic. So sequence A000664, counting graphs with n edges and no isolated vertices, is a U-sequence.

5. Groups and enumeration

We now come to the most flexible method of constructing oligomorphic groups, namely Fraïssé's Theorem.

5.1. Homogeneous structures

The groups will be automorphism groups of certain structures which we may take to be *relational structures*, that is, collections of relations of various arities on the ground set X. Structures such as graphs and partial orders can be described by a single binary relation, but in general we do not restrict the arities of the relations, and also permit an infinite number of relations. An *induced substructure* of a

relational structure on a subset Y of its domain is obtained by restricting all of the relations to Y.

A structure M on the domain X is *homogeneous* if it has the following property: any isomorphism between finite induced substructures of M can be extended to an automorphism of M.

The *age* of a relational structure M is the class of all finite relational structures which are embeddable in M as induced substructures (that is, which are isomorphic to induced substructures of M).

Now the key observation is the following:

> Let M be a homogeneous relational structure, and G its automorphism group. Then the U-sequence and the L-sequence of G enumerate the unlabeled and labeled structures respectively in the age of M.

That is, $f_n(G)$ is the number of unlabeled n-element structures embeddable in M: we count structures up to isomorphism. And $F_n(G)$ is the number of labeled n-element structures embeddable in M: that is, structures on the domain $\{1, 2, ..., n\}$ which are embeddable in M.

This application explains the terms "U-sequence" and "L-sequence".

5.2. Fraïssé's Theorem

Now it is important to know: which enumeration problems arise in this way? That is, how do we recognise the ages of homogeneous relational structures? This question is answered by *Fraïssé's Theorem*:

> **Theorem.** A class K of finite relational structures is the age of a countable homogeneous relational structure if and only if it satisfies the following four conditions:
>
> - K is closed under isomorphism;
> - K is closed under taking induced substructures;
> - K has only countably many members up to isomorphism;
> - K has the Amalgamation Property (see below).
>
> If these conditions hold, then the countable homogeneous structure whose age is K is unique up to isomorphism.

The class K has the *Amalgamation Property* if the following holds:

> Whenever A, B_1, B_2 are structures in K and f_i is an embedding of A into B_i for $i = 1, 2$,

then there exists a structure C in K and embeddings g_i of B_i in C for $i = 1, 2$ such that $g_1 f_1 = g_2 f_2$.

Effectively this means that two structures with a common substructure can be glued together along the common substructure.

The first three conditions are automatic in most cases. Indeed, in the situation of oligomorphic groups, we will have the stronger condition that the number of n-element structures in M (up to isomorphism) is finite for each n.

A class of finite structures satisfying the hypotheses of Fraïssé's Theorem is called a *Fraïssé class*. Thus the sequences enumerating unlabeled and labeled structures in any Fraïssé class are U- and L-sequences respectively. Conversely, it can be shown than any U- or L-sequence counts structures in some Fraïssé class.

The group S arises from the Fraïssé class of finite sets with no structure, and A from the class of finite linearly ordered sets.

For a slightly less simple example, the class of finite graphs is a Fraïssé class; the corresponding homogeneous structure is the so-called *countable random graph* (see [6]. The corresponding U- and L-sequences are A000088 and A006125 respectively. Many more examples exist.

If the transitive group G is associated with the Fraïssé class K, then the point stabilizer in G is associated with the class of "rooted K-structures" (that is, K-structures with a distinguished point, counted by the number of non-distinguished points).

5.3. Cycle index again

If G is the automorphism group of a homogeneous structure associated with a Fraïssé class K, then the modified cycle index of G is related to K as follows:

- Take representatives of the isomorphism classes of K-structures.
- For each representative, calculate the (ordinary) cycle index of its automorphism group.
- Sum these cycle indices.

This approach to enumeration is related to that of Joyal [7]; see also [1].

5.4. Strong Amalgamation

In the Amalgamation Property, we allow the possibility that when we glue the two structures together, the overlap is larger than intended. We say that the class K has the *Strong Amalgamation Property* if it is

possible to make the amalgamation so that no extra points are glued together. Formally, in terms of our statement of the Amalgamation Property, we require the following:

> If $g_1(b_1) = g_2(b_2)$, for some elements b_1, b_2 of B_1, B_2 respectively, then there exists an element a in A such that $f_1(a) = b_1$ and $f_2(a) = b_2$.

Now suppose that we have two Fraïssé classes K and L, both of which have the Strong Amalgamation Property. Let K *and* L denote the class of finite sets carrying both a K-structure and an L-structure (independently). Then K *and* L also has the Strong Amalgamation Property.

Note that the number of labeled n-element structures in K *and* L is the product of the numbers in K and L. So, if the Strong Amalgamation Property holds, then L-sequences can be multiplied term-by-term. The position for U-sequences is not so straightforward because of the possible existence of automorphisms.

From this construction, we get the following result.

> Let G be an oligomorphic group associated with a Fraïssé class K having the Strong Amalgamation Property. Then there is an oligomorphic group G^* whose U-sequence is the L-sequence of G.

We take G^* to be the group associated with the Fraïssé class K *and* L, where L is the class of linear orders.

This shows that many L-sequences are also U-sequences.

There is a group-theoretic test for the Strong Amalgamation Property. If G is associated with the Fraïssé class K, then K has the Strong Amalgamation Property if and only if the stabilizer in G of any finite number of points has no additional fixed points.

6. The inverse Euler transform

The **EULER** transform, as well as being associated with the group S, does several other jobs. One of these concerns graded algebras. If A is a graded algebra which is a polynomial algebra in a family of homogeneous generators (with only finitely many of each degree), then the sequence giving the dimensions of the homogeneous components of A is the **EULER** transform of the sequence counting generators by degree.

With each oligomorphic permutation group G, we can associate a graded algebra A^G, with the property that the dimension of its n^{th} homogeneous component is $f_n(G)$. (Details are given in [3] or [5].) In some

cases, A^G can be shown to be a polynomial algebra. Typically this occurs when G is associated with a Fraïssé class (such as graphs) with a "good notion of connectedness", and polynomial generators correspond to connected structures.

Here is a summary of some positive results on the polynomial question.

- For $G=S$ (or $G=A$), the algebra A^G is a polynomial algebra in one generator of degree 1.
- Direct product of permutation groups corresponds to tensor product of algebras, and so preserves the polynomial property (and the numbers of generators of each degree are simply added).
- If G is a finite permutation group, then $A^{S\ Wr\ G}$ is isomorphic to the algebra of invariants of G. Hence, if $G=S_k$, it is a polynomial algebra, with generators of degrees 1, 2, ..., k.
- For any oligomorphic group G, the algebra $A^{G\ Wr\ S}$ is a polynomial algebra; the number of generators of degree n is equal to $f_n(G)$.

The process can be reversed. If the inverse Euler transform **EULERi**$(f_n(G))=(a_n)$ is a "familiar" sequence (one listed in the Encyclopedia), we might suspect that A^G is a polynomial algebra, and try to prove this by associating generators with objects counted by (a_n).

A linearly ordered set of size n with its elements coloured red and blue can be identified with a word of length n over a 2-letter alphabet. The fact that any such word can be uniquely written as a product of Lyndon words (those which are lexicographically smaller than all their cyclic shifts) in decreasing lexicographical order shows that the **EULERi** transform of the sequence of powers of 2 is the sequence counting Lyndon words. This sequence is A001037, which also counts necklaces with two colours of beads having no rotational symmetries, or irreducible polynomials over GF(2). It is known (see [5]) that, for at least one group G whose U-sequence is the sequence of powers of 2, the algebra A^G is polynomial.

In a similar way, sequence A000045 (Fibonacci numbers) counts words in a and b with no two repeated as. If we shift the sequence right one place, we can assume that the words do not end with an a. The Lyndon factors of such a word themselves have no two repeated as, and thus correspond to necklaces with no two consecutive red beads (excluding the necklace with just one red bead), which are counted by sequence A006206.

Here are three related problems of this type, where A^G is not known to be a polynomial algebra.

- There are several groups G for which $(f_n(G))$ is sequence A000079 (powers of two, sometimes shifted right). Examples include $A\ Wr\ A$, and the group associated with the Fraïssé class of linear orders with points coloured red and blue. The **EULERi** transform of A000079 is A001037 (necklaces, or irreducible polynomials over GF(2)). For the second example mentioned, the algebra is polynomial (see above); this is not known for the first.
- The class K of two-graphs is a Fraïssé class; the corresponding U-sequence is A002854. Mallows

and Sloane [9] showed that the same sequence counts even (or Eulerian) graphs. These do not form a Fraïssé class, but do have a "good notion of connectedness"; the **EULERi** transform of A002854 is A003049 (connected Eulerian graphs).

- The group $G = S_2\ Wr\ A$ realises the sequence of Fibonacci numbers. As noted above, the **EULERi** transform is the sequence of "generalized Fibonacci numbers". Is A^G polynomial?

7. List of examples

The list of examples will be kept in a separate file and will be updated regularly.

8. Acknowledgments

I am very grateful to Christian G. Bower for many helpful comments (and a number of additional examples).

Abstract: In 1991 the author investigated a class of lattice paths that are connected with the Catalan numbers in an unusual way. Soon after, combinatorial proofs for these results were found independently by Krattenthaler and Sagan, and are included here as an Addendum. There is also an extensive annotated bibliography.

Editorial Note: Although the Encyclopedia of Integer Sequences contains numerous references to this paper, originally written in 1991, it has never before been published. This updated version is included in the *Journal of Integer Sequences* at the invitation of the editors.

1. Introduction

Bill Sands [**9**, where the problem is stated without the result (1)] noticed that the number of different walks of n steps between lattice points, each in a direction N, S, E or W, starting from the origin and remaining in the upper half-plane, is

$$w_n = \binom{2n+1}{n} \qquad (1)$$

and asked for a short proof. What is wanted is a simple ``choice" argument. This is sequence A001700 in [**10**]: my first attempt was by induction from the formula

$$w_n = 4w_{n-1} - c_n \qquad (2)$$

since a walk of length n is one more step in one of the four directions N, S, E or W, than a walk of length n-1, except that a southerly step is not allowed if the walk of length n-1 terminated on the x-axis, and it is well known that the number of such walks is the n-th Catalan number.

But it is *not* well known! It doesn't occur among the 31 manifestations listed by Kuchinski [**6**], nor can we immediately see any simple correspondence between the walks and any of the manifestations. However, first let us assume that it is true, and that (1) holds with n-1 in place of n. Then

$$\begin{aligned} 4w_{n-1} - c_n &= 4\binom{2n-1}{n-1} - \frac{1}{n+1}\binom{2n}{n} \\ &= \frac{4(2n-1)!}{n!(n-1)!} - \frac{(2n)!}{n!(n+1)!} \\ &= \frac{(2n-1)!}{n!(n+1)!}\{4n(n+1) - 2n\} \\ &= \frac{(2n)!(2n+1)}{n!(n+1)!} = \binom{2n+1}{n} \end{aligned}$$

What **is** well known is that the number of walks of 2*n* steps, each N or E, from (0,0) to (*n*,*n*), which don't cross the diagonal $y = x$, or the number of walks of 2*n*+2 steps from (0,0) to (*n*+1,*n*+1) which stay strictly above the diagonal, is c_n, the *n*-th Catalan number. This is clearly the same as the number of walks of 2*n* steps on the positive *x*-axis, starting and finishing at the origin.

2. The one-dimensional problem

Let us look at this one-dimensional analog of the Sands problem. We can exhibit the numbers of walks, *w*(*n*,*x*), of *n* unit steps, starting at (0,0) and ending at (*x*,0), $x \geq 0$, in a ``Pascal semi-triangle" (Fig. 1).

Figure 1: Numbers of walks, *w*(*n*,*x*), on the positive *x*-axis.

Columns $x = 0$ and $x = 1$ contain the Catalan numbers, sequence A000108, as already earnested; column $x = 3$ (sequence A002057) also occurs in connexion with partitioning a polygon [**1**]. Columns $x = 2, 4, 6, 8, 10, 12$ are sequences A000245, A000344, A000588, A001392, A000589, A000590 in [**10**]: they are Laplace transform coefficients: more precisely, $w(2n,2k)$ is denoted in [**7**] by C_k, which is defined by:

$$(2\cos\theta)^{2n}\sin\theta = \sum_{k=0}^{n} C_k \sin(2k+1)\theta \qquad (3)$$

Presumably there is an analogous formula for $w(2n+1,2k+1)$; compare equation (11) below. Columns $x = 5, 7, 9$ are sequences A003517, A003518, A003519. The row sums in Fig. 1, shown at the right, are the central binomial coefficients, A001405. (The triangle of numbers in Fig. 1 now forms sequences A008315 and A052173 in [**10**], where this is referred to as a Catalan triangle. See also sequence A047072.)

The first table in Cayley's paper [**1**] is for the number of partitions of an r-gon into k parts by non-intersecting diagonals. His column $k = 1$ is our main diagonal, and his column $k = 2$ is our third diagonal (starting at $(n,x) = (4,0)$). More generally, his column k is our diagonal starting at $(2k,0)$, except that his entries contain an extra factor $(x+k-2)!/(x+1)!(k-2)!$, a generalized Catalan number: in fact, for $x = k-2$ it is c_{k-2}. Cayley attributes his results to [**4**] and [**11**]: the latter paper gives some history, mentioning Terquem, Lamé, Rodrigues, Binet and Catalan.

We omit zero values of $w(n,x)$ from our table: it's fairly obvious that $w(n,x) = 0$ if n and x are of opposite parity, or if $x > n$. It's not too difficult to find formulas for the first few diagonals:

$$w(n,n) = 1, w(n,n-2) = n-1, w(n,n-4) = \frac{1}{2}n(n-3), w(n,n-6) = \frac{1}{6}n(n-1)(n-5)$$

In fact there is a comparatively simple formula for all the entries in Figure 1:

$$w(n,x) = \binom{n}{r} - \binom{n}{r-1} \qquad (4)$$

where $r = \frac{1}{2}(n-x)$. Indeed, the formula (4) also works in the apocryphal cases mentioned above, if we take the reasonable interpretation that $\binom{n}{r} = 0$ if $r < 0$, or if $n < r$, or if r is not an integer. We shall do this: note that the usual formulas, such as

$$\binom{n}{r} = \binom{n-1}{r} + \binom{n-1}{r-1} \qquad (5)$$

and (13) still hold in these cases. Formula (4) is easily proved by induction, since

$$\begin{aligned} w(n,x) &= w(n-1,x-1)+w(n-1,x+1) \\ &= \binom{n-1}{r}-\binom{n-1}{r-1}+\binom{n-1}{r-1}-\binom{n-1}{r-2} \\ &= \binom{n}{r}-\binom{n}{r-1} \end{aligned}$$

The well known result that we mentioned is the special case

$$w(2n,0)=\binom{2n}{n}-\binom{2n}{n-1}=\frac{1}{n+1}\binom{2n}{n}=c_n$$

The total number, $w(n)$, of walks of length n is

$$\begin{aligned} w(n,n) &+ w(n,n-2)+w(n,n-4)+\ldots \\ &= \left[\binom{n}{0}-\binom{n}{-1}\right]+\left[\binom{n}{1}-\binom{n}{0}\right]+\ldots+\left[\binom{n}{k}-\binom{n}{k-1}\right]=\binom{n}{k} \end{aligned}$$

where $n-2k = 0$ or 1 according as n is even or odd: i.e.

$$\binom{2k}{k} \quad \text{or} \quad \binom{2k+1}{k}.$$

Here it is clear that the number of walks of even length is just twice the number of walks of (odd) length one less:

$$2\binom{2k+1}{k}=\frac{2(k+1)(2k+1)!}{(k+1)k!(k+1)!}=\binom{2k+2}{k+1}.$$

Is there a simple ``choice" argument for walks of odd length? If you ``know" the Catalan number result, then we can use a device similar to formula (2):

$$\begin{aligned} w(2k+1) &= 2w(2k)-c_k \qquad (6) \\ &= 2\binom{2k}{k}-\frac{1}{k+1}\binom{2k}{k} \\ &= \frac{2k+1}{k+1}\binom{2k}{k}=\binom{2k+1}{k} \end{aligned}$$

but this has an air of circularity about it, or at best may be using a sledgehammer to crack a nut.

3. The two-dimensional problem

Return to the original problem: we can solve it if we go into more detail than most people would deem desirable. The numbers, $w_n(x,y)$, of walks of *n* steps from (0,0) to (*x*,*y*), which remain in the half-plane $y \geq 0$, may be exhibited in a ``Pascal semi-pyramid" whose layers are shown in Fig. 2.

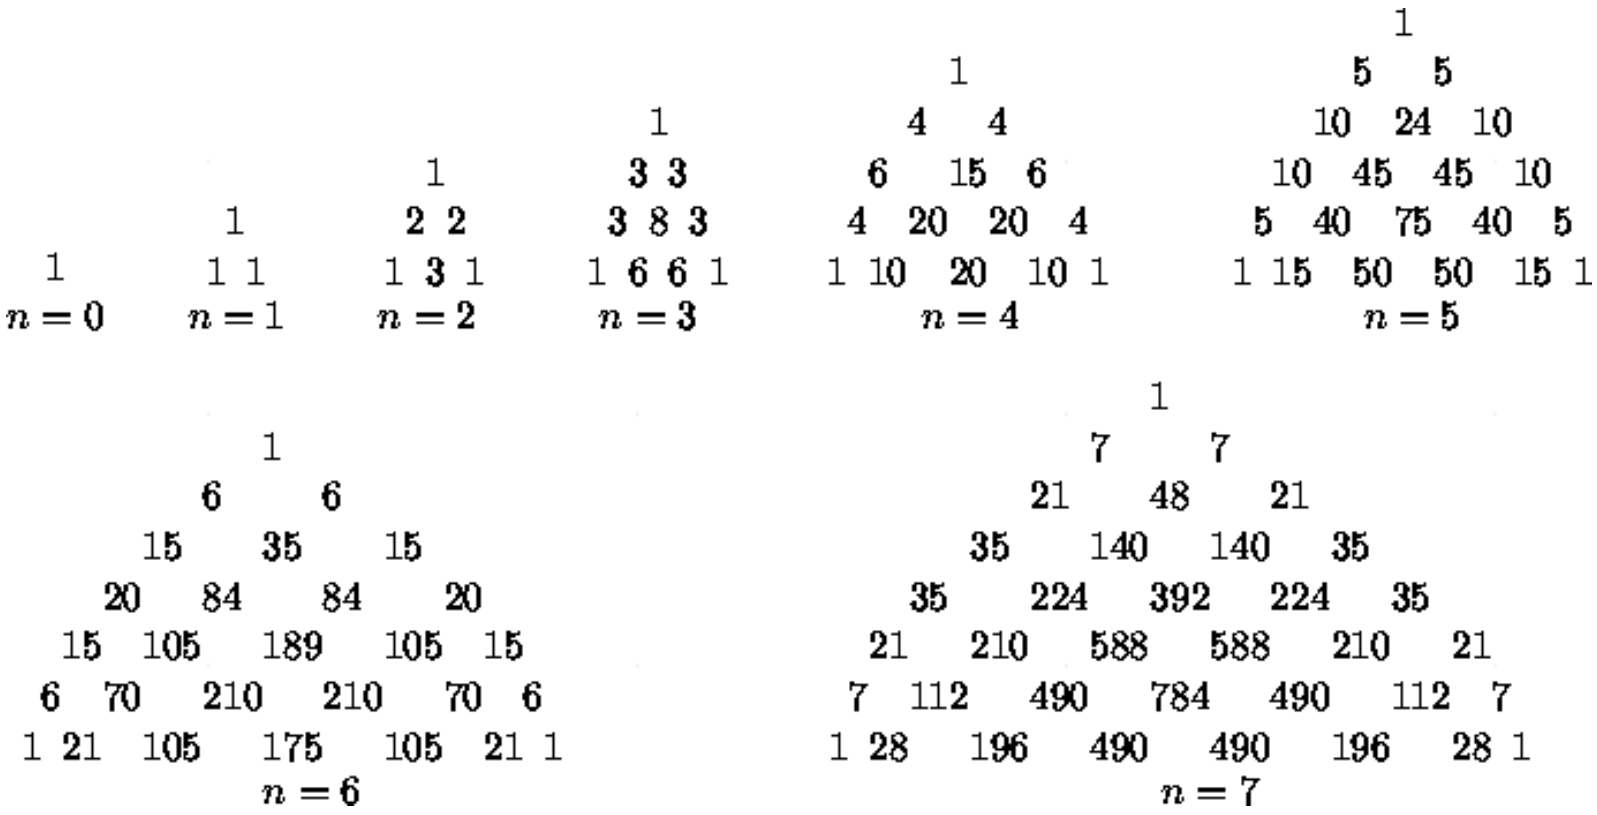

Figure 2: Layers of a Pascal semi-pyramid: values of $w_n(x,y)$.

If we sum the rows in the layers of Fig. 2 we obtain the numbers, $w_n(y)$, of walks of *n* steps which start at (0,0) and end at distance *y* from the *x*-axis. These are shown in Fig. 3. We shall see that a special case is, as we have already earnested,

$$w_n(0) = c_{n+1}. \qquad (7)$$

n	w_n	$w_n(0)$	$w_n(1)$	$w_n(2)$	$w_n(3)$	$w_n(4)$	$w_n(5)$	$w_n(6)$	$w_n(7)$	$w_n(8)$	$w_n(9)$	$w_n(10)$

Figure 3: Sums of rows of Fig. 2: values of $w_n(y)$.

(The triangle of numbers in Fig. 2 now forms sequences A039598 and A050166 in [**10**].)

In turn, the row sums of Fig. 3 are the total numbers, w_n, of Sands-type walks of length *n*. They are listed in column two of Fig. 3, and we will confirm another of our earlier statements:

$$w_n = \binom{2n+1}{n}. \qquad (8)$$

At risk of losing some interesting heuristics, we again leap to the conclusion

$$w_n(x,y) = \binom{n}{r}\binom{n}{s} - \binom{n}{r-1}\binom{n}{s-1} \qquad (9)$$

where $r = \frac{1}{2}(n+x-y), s = \frac{1}{2}(n-x-y)$.

The obvious symmetry $w_n(x,y) = w_n(-x,y)$ is reflected in formula (9), since changing the sign of *x* is equivalent to interchanging *r* and *s*. It is also clear that
(a) if $n+x+y$ is odd, then *r*, *s* are not integers, and
(b) if $|x|+y > n$, then at least one of *r*, *s* is negative,
so that in either of these cases,

$$w_n(x,y) = 0.$$

We can prove (9) inductively from the recursion (10), which states that the last step was either N, S, E or W:

$$w_n(x,y) = w_{n-1}(x,y-1) + w_{n-1}(x,y+1) + w_{n-1}(x-1,y) + w_{n-1}(x+1,y) \qquad (10)$$

Notice that the sums of the three arguments in the five terms are all of the same parity. If this is odd, then all the terms are zero. But if (*r*,*s*) are integers, then the corresponding values for the four terms on the right of (10) are

$$(r,s), \quad (r\text{-}1,s\text{-}1), \quad (r\text{-}1,s), \quad (r,s\text{-}1)$$

and if we assume that formula (9) holds with *n*-1 in place of *n*, then (10) yields

$$\begin{aligned} w_n(x,y) = &\binom{n-1}{r}\binom{n-1}{s} - \binom{n-1}{r-1}\binom{n-1}{s-1} + \binom{n-1}{r-1}\binom{n-1}{s-1} - \binom{n-1}{r-2}\binom{n-1}{s-2} \\ &+ \binom{n-1}{r-1}\binom{n-1}{s} - \binom{n-1}{r-2}\binom{n-1}{s-1} + \binom{n-1}{r}\binom{n-1}{s-1} - \binom{n-1}{r-1}\binom{n-1}{s-2} \end{aligned}$$

which becomes formula (9) after some more or less tedious manipulation, depending on one's ingenuity or symbol manipulator.

To find $w_n(y)$, sum (9) over *x*:

$$\begin{aligned} w_n(y) &= \sum_{x=-n+y}^{x=n-y} w_n(x,y) = \sum_{r=0}^{2(n-y)} w_n(x,y) \\ &= \left[\binom{n}{0}\binom{n}{n-y} + \binom{n}{1}\binom{n}{n-y-1} + \cdots + \binom{n}{n-y}\binom{n}{0}\right] - \\ &\quad \left[\binom{n}{-1}\binom{n}{n-y-1} + \binom{n}{0}\binom{n}{n-y-2} + \cdots + \binom{n}{n-y-2}\binom{n}{0}\right] \end{aligned}$$

The two brackets are the coefficients of t^{n-y} and of t^{n-y-2} in the expansion of $(1+t)^n(1+t)^n$, so that

$$w_n(y) = \binom{2n}{n-y} - \binom{2n}{n-y-2}$$

which may be rewritten as

$$w_n(y) = \binom{2n+1}{n-y} - \binom{2n+1}{n-y-1}. \qquad (11)$$

On comparing this with (4) we see that

$$w_n(y) = w(2n+1, 2y+1),$$

the number of odd length one-dimensional walks which finish, of course, at an odd distance from the origin.

In particular, (7) is the same as the number of walks from (0,0) to (n,n+1) which begin with a northward step and do not cross the line joining start to finish, $w(2n+1,1)$, which is

$$\begin{aligned} w_n(0) &= \binom{2n+1}{n} - \binom{2n+1}{n-1} = \frac{(2n+1)!}{n!(n+2)!}(n+2-n) \\ &= \frac{2(n+1)(2n+1)!}{(n+1)!(n+2)!} = \frac{1}{n+2}\binom{2n+2}{n+1} = c_{n+1}, \end{aligned}$$

the (n+1)th Catalan number.

Finally, summing (11) from $y = 0$ to $y = n$ gives (8).

4. Walks in the positive quadrant

We could ask similar questions concerning walks which do not stray outside the positive quadrant. The numbers of such walks now form a ``Pascal quarter-pyramid", which is exhibited in Fig. 4.

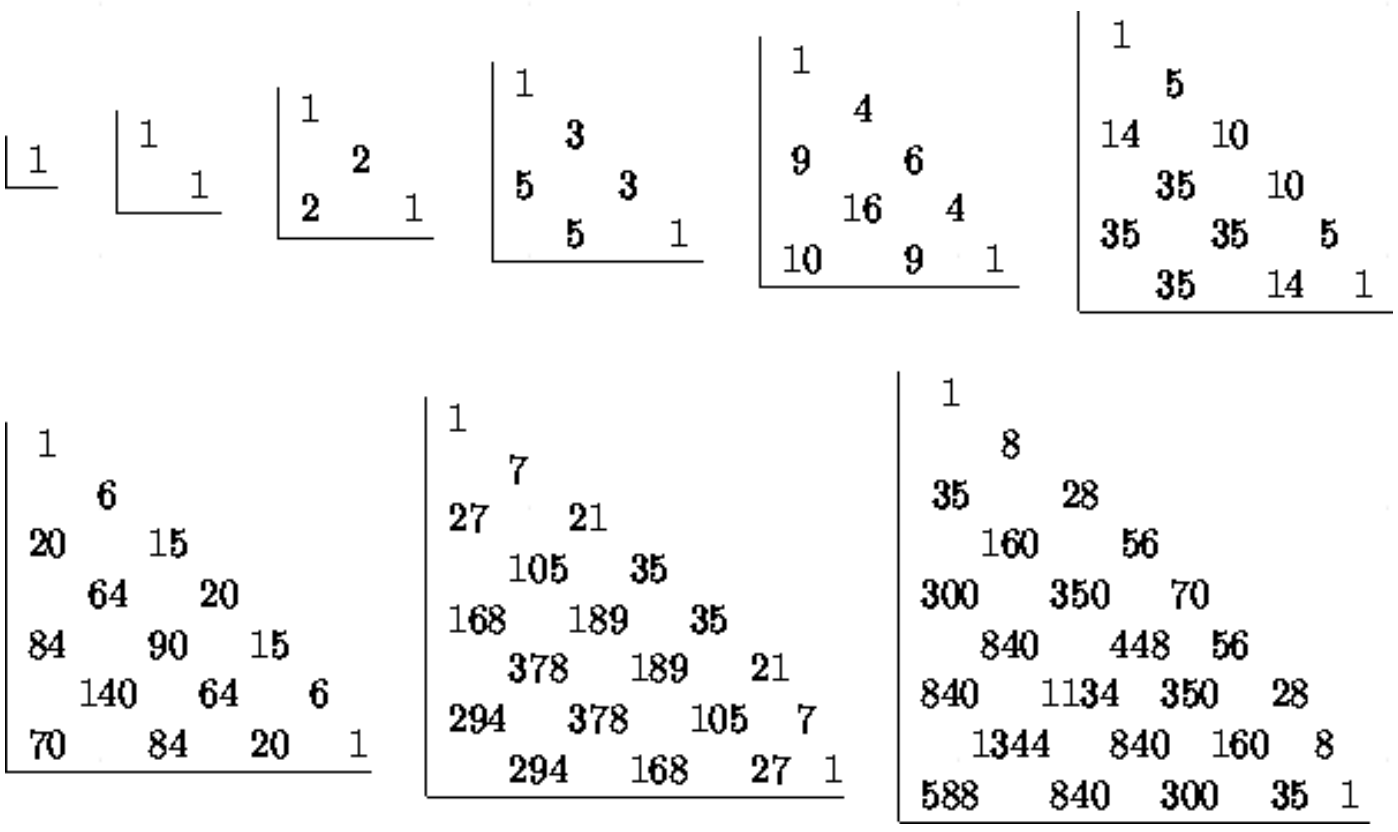

Figure 4: Layers of a Pascal quarter-pyramid: values of $w'_n(x,y)$.

The entries in Fig. 4 are given, again without motivation, by

$$w'_n(x,y) = \binom{n}{r}\binom{n+2}{s} - \binom{n+2}{r+1}\binom{n}{s-1} \qquad (12)$$

where $r = \frac{1}{2}(n+x-y)$, $s = \frac{1}{2}(n-x-y)$ as before. Notice that interchange of *x* and *y* keeps *s* fixed and replaces *r* by *n*-*r*. So the symmetry

$$w'_n(y,x) = w'_n(x,y)$$

follows from the symmetries

$$\binom{n}{r} = \binom{n}{n-r} \quad \text{and} \quad \binom{n+2}{r+1} = \binom{n+2}{n-r+1}. \qquad (13)$$

We may prove (12) as we proved (9), since $w'_n(x,y)$ also satisfies the relation (10).

A remarkable coincidence is that

$$w'_{2k-1}(0,1) = \frac{1}{2}c_k c_{k+1}$$

is the number of inequivalent Hamiltonian rooted maps on 2*k* vertices (sequence A000356 in [**10**]) although Tutte [**12**] doesn't give the formula in terms of Catalan numbers. Is there yet another opportunity for a purely combinatorial proof?

n	$w'_n(0)$	$w'_n(1)$	$w'_n(2)$	$w'_n(3)$	$w'_n(4)$	$w'_n(5)$	$w'_n(6)$	$w'_n(7)$	$w'_n(8)$	$w'_n(9)$
0	1									
1	1	1								
2	3	2	1							
3	6	8	3	1						
4	20	20	15	4	1					
5	50	75	45	24	5	1				
6	175	210	189	84	35	6	1			
7	490	784	588	392	140	48	7	1		
8	1764	2352	2352	1344	720	216	63	8	1	
9	5292	8820	7560	5760	2700	1215	315	80	9	1

Figure 5: Sums of rows of Fig. 4: values of $w'_n(y)$.

Figure 5 is obtained by summing the rows of Fig. 4, and we may find $w'_n(y)$, the number of walks in the positive quadrant which finish at distance y from the x-axis, by summing (12) from $x = 0$ to $x = n$-y.

$$\begin{aligned} w'_n(y) &= \left[\binom{n}{n-y}\binom{n+2}{0} - \binom{n+2}{n-y+1}\binom{n}{-1}\right] \\ &\quad + \left[\binom{n}{n-y-1}\binom{n+2}{1} - \binom{n+2}{n-y}\binom{n}{0}\right] \\ + \cdots &+ \left[\binom{n}{\frac{1}{2}(n-y)}\binom{n+2}{\frac{1}{2}(n-y)} - \binom{n+2}{\frac{1}{2}(n-y)+1}\binom{n}{\frac{1}{2}(n-y)-1}\right] \end{aligned}$$

if n-y is even, but with the last term replaced by

$$\left[\binom{n}{\frac{1}{2}(n-y+1)}\binom{n+2}{\frac{1}{2}(n-y-1)} - \binom{n+2}{\frac{1}{2}(n-y+3)}\binom{n}{\frac{1}{2}(n-y-3)}\right]$$

if n-y is odd.

Put n-$y = 2k$ or $2k+1$ and

$$w'_n(y) = \begin{cases} \binom{n+1}{k}\binom{n}{k} - \binom{n+1}{k}\binom{n}{k-1} & \text{if } n-y = 2k \\ \binom{n+1}{k}\binom{n}{k+1} - \binom{n+1}{k+1}\binom{n}{k-1} & \text{if } n-y = 2k+1 \end{cases}$$

In particular, if $y = 0$,

$$\begin{aligned} w'_n(0) &= \frac{1}{k+1}\binom{2k}{k}\binom{2k+1}{k} \quad \text{or} \quad \frac{1}{k+2}\binom{2k+2}{k+1}\binom{2k+1}{k} \\ \text{i.e.} &\qquad \binom{2k+1}{k}c_k \quad \text{or} \quad \binom{2k+1}{k}c_{k+1} \end{aligned}$$

according as $n = 2k$ or $n = 2k+1$, where c_k is the k-th Catalan number.

(The first few columns of Fig. 5 produce sequences A005558, A005559, A005560, A005561, A005562; and the triangle itself gives A052174.)

5. The Manhattan metric

For walks in the positive quadrant it is more natural and symmetrical to ask for the numbers of walks which terminate at various distances from the origin, using the ``Manhattan metric", $x+y = n-2s$. Figure 6 shows the sums of the diagonals of Fig. 4.

w'_n	n	0	1	2	3	4	5	6	7	8	9	10	11
1	0	1											
2	1		2										
6	2	2		4									
18	3		10		8								
60	4	10		34		16							
200	5		70		98		32						
700	6	70		308		258		64					
2450	7		588		1092		642		128				
8820	8	588		3024		3414		1538		256			
31752	9		5544		12276		9834		3586		512		
116424	10	5544		31680		43230		26752		8194		1024	
426888	11		56628		141570		138424		69784		18434		2048

Figure 6: Sums of diagonals of Fig.4: values of $w''_n(x+y)$.

The entries in Fig. 6 are

$$w''_n(x+y) = w''_n(n-2s) = \sum_{x+y=n-2s} w'_n(x,y)$$

$$= \binom{n+2}{s}\left[\binom{n}{s}+\binom{n}{s+1}+\cdots+\binom{n}{n-s}\right] - \binom{n}{s-1}\left[\binom{n+2}{s+1}+\binom{n+2}{s+2}+\cdots+\binom{n+2}{n-s+1}\right]$$

Except for small values of *s*, the truncated binomial expansions do not seem to have a simple closed form:

$$w''_n(n) = 2^n$$

$$w''_n(n-2) = (n-2)2^n + 2$$

$$w''_n(n-4) = \frac{1}{2!}(n^2-5n+2)2^n + n^2 + 3n - 2$$

$$w''_n(n-6) = \frac{1}{3!}[n(n^2-9n+14)2^n + n(n^3+4n^2-n-28)]$$

$$w''_n(n-8) = \frac{1}{4!}n(n-1)(n^2-13n+34)2^n + \frac{1}{72}n(n-1)(n^4+4n^3-n^2-64n-204)$$

An amusing curiosity is that $w''_n(n-2)$ (sequences A036799 and A000337) is twice the genus of the (n+2)-dimensional cube [**8**, or see Theorem 14 in **3**].

The total number of walks, w'_n (A005566) , the left hand column in Fig. 6, has, on the other hand, the comparatively simple formula

$$w'_n = \binom{n}{\lfloor n/2 \rfloor} \binom{n+1}{\lfloor (n+1)/2 \rfloor} \qquad (14)$$

which again seems to beg for a simple proof.

The columns in Fig. 6 give sequences A005568 and A005569; the diagonals give A000079, A036799 and A005567; and the triangle itself forms A052175 and A052176.

If there is no restriction on the two-dimensional walks, i.e. if they may wander on either side of the *x*- and *y*-axes, then it is fairly easy to see that their number of length *n*, from (0,0) to (*x*,*y*), is

$$\binom{n}{r}\binom{n}{s} \qquad (15)$$

where *r* and *s* are as before, but calculated using the absolute values of *x* and *y*.

Of course, the total number of walks of length *n* is 4^n .

6. The three-dimensional problem

Although we certainly haven't found the most aesthetic proofs, the comparative simplicity of the final results tempts us to ask what happens in three dimensions. Let $W_n(x,y,z)$ be the number of walks of *n* steps, each in a direction N, S, E, W, up, or down, from (0,0,0) to (*x*,*y*,*z*), which never go below the (*x*,*y*)-plane. We will not attempt to depict the four-dimensional ``Pascal semi-pyramid", but the sums of its layers now give $W_n(z)$, the number of walks terminating at height *z* above the (*x*,*y*)-plane, and this satisfies the recurrence

$$W_n(z) = W_{n-1}(z-1) + 4W_{n-1}(z) + W_{n-1}(z+1) \qquad (16)$$

which may be used to produce the array of Fig. 7.

Each entry in Fig. 7 is the sum of four times the entry immediately above it and the two neighbors of that entry, e.g.

$$W_5(2) = 4 \cdot 99 + 288 + 16 = 700.$$

W_n	n	0	1	2	3	4	5	6	7	8	9
1	0	1									
5	1	4	1								
26	2	17	8	1							
139	3	76	50	12	1						
758	4	354	288	99	16	1					
4194	5	1704	1605	700	164	20	1				
23460	6	8421	8824	4569	1376	245	24	1			
132339	7	42508	48286	28476	10318	2380	342	28	1		
751526	8	218318	264128	172508	72128	20180	3776	455	32	1	
4290838	9	1137400	1447338	1026288	481200	156624	35739	5628	584	36	1

Figure 7: Walks in three dimensions: values of $W_n(z)$.

(The row sums in Fig. 7 give A005573; the columns give A005572, A052177 and A052178; and the triangle itself forms A052179.)

We again suppress the details of discovery of the general formula, and of its inductive proof: these details seem to be more complicated than before, and we found no obvious manifestation of the Catalan numbers. The simplest expression for $W_n(z)$ that we have so far found is not in closed form:

$$W_n(n-v) = a_{n,0}\binom{n}{v} + a_{n,1}\binom{n}{v-1} + \ldots + a_{n,t}\binom{n}{v-t}$$

where $t = \lfloor (v+2)/2 \rfloor$ and the coefficients $a_{n,u}$ are of shape

$$a_{n,u} = \left[\binom{v-u}{u} - 4^2\binom{v-u}{u-2}\right] 4^{v-2u}$$

although there are, of course, closed form expressions for small values of *v*:

$$
\begin{aligned}
W_n(n) &= 1 \\
W_n(n-1) &= 4n \\
W_n(n-2) &= (n-1)(8n+1) \\
W_n(n-3) &= \frac{4}{3}n(n-2)(8n-5) \\
W_n(n-4) &= \frac{1}{6}n(n-3)(64n^2-144n+83) \\
W_n(n-5) &= \frac{2}{15}n(n-1)(n-4)(64n^2-240n+239) \\
W_n(n-6) &= \frac{1}{90}n(n-1)(n-5)(512n^3-3648n^2+8872n-7233) \\
W_n(n-7) &= \frac{2}{315}n(n-1)(n-2)(n-6)(512n^3-4800n^2+15496n-17007)
\end{aligned}
$$

We have not found a closed expression for W_n, the total number of walks of *n* steps which do not go below the (*x*,*y*)-plane, nor have we had an opportunity to examine the paper [**5**] which may contain such an expression and may overlap the present paper in other ways. The total number of *n*-step walks in *d* dimensions, without restriction, is, of course, $(2d)^n$.

7. Addendum

This addendum arises from correspondence with Christian Krattenthaler and Bruce Sagan, and a referee's report on the original (1991) version of this manuscript.

Christian Krattenthaler writes that ``...the classes of lattice paths you have considered do not seem to have been treated before". On the other hand, both he and the referee point out that formula (15) appears in Theorem 2 in [**D1**]. The referee also notes that formula (4) is in [**Fe**] and that formulas (9), (11), (12), and that for $w'_n(y)$, follow easily from (15) and the reflexion principle. However, the exciting news is that Krattenthaler supplies combinatorial proofs of almost all of the formulas, of the kind appealed for, and that Bruce Sagan also gives very similar proofs. The main item that is still missing is a combinatorial proof of the formula(s) for $w'_n(y)$.

The proofs are paraphrased below and also appear in

Richard K. Guy, Christian Krattenthaler and Bruce Sagan, Lattice paths, reflections and dimension-changing bijections, **Ars Combinatorica**, **34** (1992) 3-15; *MR* **93i**:05008.

See also: Solutions to Problem 1517, *Crux Mathematicorum*, **17** #4 (Apr 1991) 119--122.

1. Proof of (15). Set up a correspondence between ``NSEW" paths, *p*, and *pairs* ( $p_1$ , $p_2$ ) of ``NE" paths: if the *m*-th step of *p* is N, S, E, W, then the *m*-th step of p_1 is respectively N, E, E, N, and that of p_2 is N, E, N, E. Then the ``NSEW" paths of *n* steps from (0, 0) to (*x*, *y*) are in 1-1 correspondence with pairs ( $p_1$ , $p_2$ ) of ``NE" paths, where p_1

runs from (0, 0) to (*r*, *n*-*r*) and $\bar{p}_2$ from (0, 0) to (*s*, *n*-*s*), where $r = \frac{1}{2}(n+x-y)$ and $s = \frac{1}{2}(n-x-y)$ as before.

[Algebraic detail: If the numbers of N, S, E, W steps are respectively *a*, *b*, *c*, *d*, then *n* = *a*+*b*+*c*+*d*, *x* = *c*-*d*, *y* = *a*-*b*, *r* = *b*+*c*, *n*-*r* = *a*+*d*, *s* = *b*+*d*, *n*-*s* = *a*+*c* and *r*, *s* are as stated.]

But the number of ``NE" paths from (0, 0) to (*k*, *l*) is $\binom{k+l}{k}$, so the number of NSEW paths from (0, 0) to (*x*, *y*) is

$$\binom{n}{r}\binom{n}{s},$$

i.e., formula (15).

2. Proof of (9). To count NSEW paths of *n* steps from (0, 0) to (*x*, *y*) which do not go below the *x*-axis, use the reflexion principle. We must subtract the number of paths which cross the *x*-axis. Each of these has a first point, say *P*, for which *y* = -1. Relect the initial portion *OP* in the line *y* = -1, giving a 1-1 correspondence between paths which cross the *x*-axis and paths from (0, -2) to (*x*, *y*). Their number is the same as the total number of paths already counted, except that *y* is replaced by *y*+2, i.e., *r* and *s* are each decreased by 1. This gives formula (9):

$$w_n(x,y) = \binom{n}{r}\binom{n}{s} - \binom{n}{r-1}\binom{n}{s-1}.$$

3. Proof of (12). Reflexion may also be used to count the NSEW paths which stay in the positive quadrant. A second relexion in *x* = -1 together with the inclusion-exclusion principle shows that this number is

#{paths from (0, 0) to (*x*, *y*)} - #{paths from (0, -2) to (*x*, *y*)} - #{paths from (-2, 0) to (*x*, *y*)} + #{paths from (-2, -2) to (*x*, *y*)}

$$= \binom{n}{r}\binom{n}{s} - \binom{n}{r-1}\binom{n}{s-1} - \binom{n}{r+1}\binom{n}{s-1} - \binom{n}{r}\binom{n}{s-2}$$

which easily manipulates into formula (12).

4. Proof of (11). To count the Sands-type paths, *p*, which finish at height *y*, use another correspondence with NE paths, $\bar{p}$, of twice the length. If the *m*-th step of *p* is N, S, E, W, then the (2*m*-1)-th and 2*m*-th steps of $\bar{p}$ are respectively NN, EE,NE,EN. This sets up a bijection between NSEW paths with *n* steps from (0, 0) to height *y* which do not cross the *x*-axis and NE paths from (0, 0) to (*n*-*y*, *n*+*y*) which do not cross the line *y* = *x*-1. To enumerate these, use the reflexion principle again. A path which crosses the line *y* = *x*-1 has a first point *Q* for which *y* = *x*-2. Reflect the portion *OQ* of such a path in the line *y* = *x*-2. This gives a correspondence with NE paths of 2*n* steps from (2, -2) to (*n*-*y*, *n*+*y*) whose number is $\binom{2n}{n-y-2}$. This confirms the formula displayed just before formula (11). To see (11) itself, adjoin a single N-step to the beginning of path $\bar{p}$ and again apply the reflexion principle.

Note that if we also adjoin a final E-step to the path $\bar{p}$ we see that the number of Sands-type paths with *n* steps from (0, 0) which finish on the *x*-axis is the same as the number of NE walks from (0, -1) to (*n*+1, *n*) which do not cross the line *y* = *x*-1, and this is well-known to be C_{n+1}.

5. Proof of (1). First use the correspondence of **4.** to map *p* (Sands-type, *n* steps from (0, 0) to height *y*, not crossing the *x*-axis) onto $\bar{\bar{p}}$ (NE path, 2*n*+1 steps from (0, -1) to (*n*-*y*, *n*+*y*), not crossing *y* = *x*-1). Consider the last meeting point of $\bar{\bar{p}}$ with *y* = *x*-1. The next step is an N-step, which we change to an E-step, obtaining a new path from (0, -1) to (*n*-*y*+1, *n*+*y*-1). Repeat this procedure, this time considering the last meeting point with the line *y* = *x*-2. Next consider the line *y* = *x*-3, &c. After *y* changes we arrive at a path from (0, -1) to (*n*, *n*). Since this sets up a bijection between NE paths of 2*n*+1 steps starting from (0, -1) and not crossing the line *y* = *x*-1, and NE paths from (0, -1) to (*n*, *n*) (last meeting points become first crossing points!), we obtain the total number of Sands-type paths of *n* steps,

$$\binom{2n+1}{n}.$$

B2. M.T.L. Bizley, Derivation of a new formula for the number of minimal lattice paths from (0,0) to (*km,kn*) having just *t* contacts with the line *my = nx* and having no points above this line; and a proof of Grossman's formula for the number of paths which may touch but do not rise above this line, *J. Inst. Actuar.*, **80** (1954) 55-62; MR **15**, 846d.

[Write $\phi(k,t)$ for the lattice paths with *t* contacts as described in the title and, following **G5**, write

$$F_j = [j(m+n)]^{-1}\binom{jm+jn}{jm};$$

then the author's new formula may be stated as

$$\sum \phi(k,t)x^k = [1-\exp(-F-1x-F_2x^2-\ldots)]^t.$$

The corresponding formula for $\phi_k = \sum \phi(k,t)$, namely

$$\sum \phi(k)x^k = \exp(F_1x+F_2x^2+\ldots)-1$$

is equivalent to Grossman's formula ...*J. Riordan*] [presumably $\phi_k = \phi(k)$ and the summation is over *t*.]

B3. David Blackwell & J.L. Hodges, Elementary path counts, *Amer. Math. Monthly*, **74** (1967) 801-804; Zbl. **155**, 29c.

[Consider a sequence x_0, ..., x_n with entries $x_i = \pm 1$, and let $s_i = x_0 + \ldots + x_i$ be the partial sums. The authors furnish an elementary combinatorial proof of two known theorems concerning the enumeration of such sequences relative to two parameters: the sum s_n, and the lead, or number of indices *i* for which both s_{i-1} and s_i are non-negative. *H. H. Crapo*]

Ca. L. Carlitz & J. Riordan, Two element lattice permutation numbers and their *q*-generalization, *Duke Math. J.*, **31** (1964) 371-388; MR **29** #5752.

[A two-element lattice permutation can be described in a two-dimensional lattice as a path leading from (0,0) to a point (*m,n*) (where $0 \le m \le n$) with the conditions that the path has minimum length, viz., *m+n*, and that it does not contain points (*a,b*) with *a* < *b*. It can also be described as an election for two candidates *A*, *B* with final vote (*n,m*), which is such that none of the partial results gives a majority for *B* (in the paper it is less accurately said that all partial results correctly predict the winner). The number $a_{n,m}$ of such two-element lattice permutations was determined in 1887 by J. Bertrand [**B1**, see **Ma**] as

$$a_{n,m} = (n+1-m)(n+1)^{-1}\binom{n+m}{m}.$$

The authors consider $a_n(x) = \sum_{m=0}^{n} a_{n,m}x^m$ and show that this *n*th degree polynomial is characterized by the property that $(1-x)^{n+1}a_n(x)$ has the form $1 - xP_n(x(1-x))$, where P_n is again an *n*th degree polynomial; in fact, $P_n(u) = \sum_{m=0}^{n} a_{m,m}u^m$. A number of relations are derived for the generating function $a(x,y) = \sum_{n=0}^{\infty} x^n a_n(y)$.

The authors consider these formulas as the special case ($q = 1$) of a *q*-generalization. They define the *n*th degree polynomial $a_n(x,q)$ by the condition that there exist c_0, ..., c_n such that

$$(x)_{n+1}a_n(x,q) = 1 - x\sum_{m=0}^{n} c_m(qx)^m(x)_m,$$

where $(x)_k$ denotes $(1-x)(1-qx)\ldots(1-q^{k-1}x)$. The coefficients $a_{n,m}(q)$ of this polynomial are studied in several ways.

{The reviewer remarks that $a_{n,m}(q)$ has the following combinatorial interpretation: It is the sum of all $q^{k_1+\ldots+k_m}$, where k_1, ..., k_m are integers subject to the conditions $1 \le k_1 \le \ldots \le k_m \le n$, $k_1 \ge 1$, ..., $k_m \ge m$.} *N. G. de Bruijn*]

1. Arthur Cayley, On the partitions of a polygon, *Proc. London Math. Soc.* **22** (1891) 237-262 = Coll. Math. Papers **13** (1897) 93-113.

Ci. J. Cigler, Some remarks on Catalan families, *European J. Combin.*, **8** (1987) 261-267; MR **89a**:05010.

[The author first gives a simple proof that the *r*-Catalan number $(1/((r-1)n+1))\binom{rn}{n}$ is the number of ways of parenthesizing an *r*-ary product of (*r*-1)*n*+1 factors, or equivalently, the number of *r*-ary trees with *n* points. Next he shows, using a variant of the Dvoretzky-Motzkin cycle lemma, that the number of *r*-ary trees with *n* points and t_i edges from a point to its *i*th subtree, where $\sum t_i = n-1$, is $(1/n)\binom{n}{t_1}\binom{n}{t_2}\ldots\binom{n}{t_r}$. From this formula he deduces that the number of nonnegative paths from (0,0) to (*rn*,0) with *k*+1 peaks, using the steps (1,1) and (1,1-*r*), is the generalized Runyon number $(1/n)\binom{(r-1)n}{k}\binom{n}{n-1-k}$. Finally he discusses the connexion between these results, noncrossing partitions and Sperner's theorem. *Ira Gessel*]

[Several results extending those of the reviewer and Feller, and generalized by E.S. Andersen, are given. The combinatorial formulae are obtained by one-to-one correspondence, from which asymptotic ones are computed. For instance, let s_i, i = 0, 1, 2, ..., be the successive sums in the coin-tossing game with stakes ± 1, $s_0=0$, and let $2\gamma_{2n}^{(2k)}$ denote the number of indices $i\,(i=1,\ldots,2n)$ for which either $s_i>2k$ or $s_i=2k$ but $s_{i-1}=2k+1$, where k is a non-negative integer; then

$$\mathbf{P}(\gamma_{2n}^{(2k)}=g)=\frac{1}{2^{2n}}\binom{2g}{g}\binom{2n-2g}{n-g+k},\quad g=1,2,\ldots,n-k,$$

$$\mathbf{P}(\gamma_{2n}^{(2k)} = 0) = \frac{1}{2^{2n}} \sum_{j=-k}^{k} \binom{2n}{n+j}.$$

[...In an election, candidates P and Q receive p and q votes, respectively; required the probability that the ratio of the ballots for P to those for Q will, throughout the counting, be larger than (larger than or equal to) α .]

E. O. Engleberg, On some problems concerning a restricted random walk, *J. Appl. Probability*, **2** (1965) 396-404; MR **32** #475.

[The restricted random walk in question is on a line (vertical for convenience) with unit steps up and down and prescribed numbers of each. In the terminology of Feller [**Fe**] such a walk is a polygonal path from (0,0) to $(n+m,n-m)$; it is also in one-to-one correspondence with a two-candidate election return with final vote (n,m). In election return terms, the author's main results are as follows: If $c(x;n,m)$ is the enumerator of election returns with final vote (n,m), $n \geq m$, by number of changes of lead, if $t(x;n,m)$ is the corresponding enumerator by number of ties, then

$c(x;n,m) = \sum_{k=0}^{m} a_{n+k,m-k}x^k$, $n > m$, $c(x;n,n) = 2c(x;n,n-1)$, $t(x;n,m) = \sum_{k=0}^{m} a_{n-1,m-k}(2x)^k$,

where

$$a_{n,m} = \binom{n+m}{m} - \binom{n+m}{m-1} = \frac{n+1-m}{n+1}\binom{n+m}{m}.$$

The numbers $a_{n,m}$ are the oldest ballot numbers. (For $n < m$, the enumerators in the two cases, by symmetry, are those above with n and m interchanged, a result not noticed by the author.) These results are used with obvious summations to verify the results of Feller [**Fd**] for the enumeration of unrestricted random walks by number of axis crossings and by number of zeros (of their polygonal paths). Also the limiting distribution functions of tie returns ($n = m$) are determined. Finally, the application of the results to the comparison of two empirical distributions is sketched.

{In equation (11) there are two typographical slips whose corrections will probably be evident to most readers.} *J. Riordan*]

[Referred to in review of **G3**.]

Fu. J. Fürlinger & J. Hofbauer, q-Catalan numbers, *J. Combin. Theory Ser. A*, **40** (1985) 248-264; MR **87e**:05017.

[The Catalan numbers C_n are defined by $C_n = \frac{1}{n+1}\binom{2n}{n}$ and satisfy $z = \sum_{n=1}^{\infty} C_n z^n/(1+z)^{2n}$ and $z = \sum_{n=1}^{\infty} C_n z^n(1-z)^n$. This paper surveys several q-analogs of the Catalan numbers. The authors first consider the q-Catalan numbers of **Ca**. These satisfy

$$z = \sum_{n=1}^{\infty} q^{\binom{n-1}{2}} C_n(q) \frac{z^n}{(1+z)(1+qz)\dots(1+q^{2n-1}z)}$$

and

$$z = \sum_{n=1}^{\infty} C_{n-1}(q) z^n (1-z)(1-qz)\dots(1-q^{n-1}z).$$

There is no simple explicit formula for $C_n(q)$, but there is a combinatorial interpretation in terms of inversions of certain 0-1 sequences.

Next the authors consider the *q*-Catalan numbers given by

$$c_n(\lambda;q) = \sum_{k=0}^{n} \frac{1}{[n]} \begin{bmatrix} n \\ k \end{bmatrix} \begin{bmatrix} n \\ k+1 \end{bmatrix} q^{k^2+\lambda k},$$

in which the terms are *q*-Runyon numbers. Here one defines $[n] = (q^n-1)/(q-1)$ and $\begin{bmatrix} n \\ k \end{bmatrix}$ is the *q*-binomial coefficient. For $\lambda = 1$ these reduce to $c_n(1;q) = C_n$. These *q*-Catalan numbers satisfy

$$z = \sum_{n=1}^{\infty} \frac{c_n(\lambda;q) z^n}{q^{\binom{n}{2}} (-q^{-n}z)_n (-q^{\lambda}z)^n},$$

where $(a)_n = (1-a)(1-qa)\dots(1-q^{n-1}a)$, and they have a combinatorial interpretation in terms of major indices and descents of 0-1 sequences.

A generalization which includes both types of *q*-Catalan numbers is considered next. These satisfy

$$z = \sum_{n=1}^{\infty} \frac{a^{-\binom{n}{2}} C_n(x;a,b) z^n}{(1+a^{-1}z)\dots(1+a^{-n}z)(1+xbz)\dots(1+xb^nz)}$$

and are also given a combinatorial interpretation. They also include as a special case the *q*-Catalan numbers studied in **Po**. *Ira Gessel*]

[The authors consider paths along the nonnegative integers in which each step consists of an increase of altitude of 1 (a rise), 0 (a level), or -1 (a fall). The paths are weighted to record the number of rises and levels at each altitude. The main result of the paper answers the following question: What is the sum of the weights of all paths with given initial and terminal altitudes, and with given bounds on maximum and minimum altitudes? The answer is expressed in terms of continued fractions and extends P. Flajolet's combinatorial theory of continued fractions [**Fl**]. Some classical identities for continued fractions are obtained as corollaries. *Ira Gessel*]

G4. Dominique Gouyou-Beauchamps & G. Viennot, Equivalence of the two-dimensional directed animal problem to a one-dimensional path problem, *Adv. in Appl. Math.*, **9** (1988) 334-357; MR **90c**:05009.

[A set *P* of lattice points in the plane is called a directed animal if there is a subset of *P*, whose elements are called root points, such that the root points lie on a line perpendicular to the line *y=x*, and every point of *P* can be reached from a root point by a path in *P* using only north and east steps. This paper is concerned with the enumeration of compact-rooted animals, which are animals in which the root points are consecutive. Animals which differ only by translation are considered to be equivalent.

The main result is a bijection between compact-rooted animals of size *n*+1 and paths of length *n* on the integers, with steps +1, 0 and -1. This bijection implies that there are 3^n compact-rooted animals of size *n*+1. Moreover the bijection allows the compact-rooted animals to be counted according to the number of root points. Further consequences are that the generating function for directed animals with one root point is $\frac{1}{2}((1+t)/\sqrt{1-2t-3t^2}-1)$ and that the number of directed animals of size *n* rooted at the origin and contained in the first octant $0 \le x \le y$ is the Motzkin number m_{n-1}.

The paper also contains many references to work by physicists on problems of counting animals, which arise in studying thermodynamic models for critical phenomena and phase transitions. *Ira Gessel*]

L. Gilbert Labelle, Une nouvelle démonstration combinatoire des formules d'inversion de Lagrange, *Adv. in Math.*, **42** (1981) 217-247; MR **83e**:05016.

[The purpose of this paper is to examine connexions between two classical results -- the Lagrange inversion formula for power series and Cayley's formula for the number of labelled trees on *n* vertices -- in the light of the combinatorial theory of formal series recently presented by **J** and founded on the notion of ``species of structures". Some combinatorial operations are defined over species and correspond to analytic operations over their generating functions: hence, properties of the operations over species yield identities for formal series. The authors introduce two canonical constructions which associate a new species -- ``arborescence *R*-enrichie" and ``endofonction *R*-enrichie", respectively -- to any given species *R* and proves some deep isomorphism results. These yield, as simple corollaries, some generalized versions of Cayley's formula and the Lagrange inversion formula. *Andrea Brini*]

L1. Jacques Labelle & Yeong-Nan Yeh, Dyck paths of knight moves, *Discrete Appl. Math.*, **24** (1989) 213-221; MR **90g**:05017.

[This paper enumerates lattice paths from the origin to a point along the *x*-axis which do not go below the *x*-axis, where the allowable moves are knight moves from left to right. The resulting generating function satisfies a fourth-degree polynomial equation. This compares with so-called Dyck paths, where the allowable moves are one-step diagonal moves to the right. In this classical case the resulting generating function satisfies a quadratic polynomial equation, whose solution yields the Catalan number generating function.

The authors apply their methods to paths with (*r*,*s*) knight moves, and obtain polynomial equations of higher degree. *Dennis White*]

M2. Sri Gopal Mohanty, On some generalization of a restricted random walk, *Studia Sci. Math. Hungar.*, **3** (1968) 225-241; MR **39** #1022.

[The author considers the paths of a restricted random walk starting from the origin, which at each step moves either one unit to the right or μ (positive integer) units to the left, and reaches the point $m - \mu n$ in $m+n$ steps. Random walks are considered schematically by representing each movement of the particle to the right or to the left by a horizontal or a vertical unit so that the restricted random walk corresponds to the minimal lattice paths the particle describes from the origin to (m,n). Expressions are obtained for total numbers of distinct paths under certain further conditions as follows. For a given path, say C, of such a random walk the total number of paths is found which, after each step, do not lie to the left of the corresponding point of C, and which touch C in a prescribed way in exactly r of the last s left steps. Expressions are obtained also for the number of paths crossing r times (but not necessarily reaching) a point $\alpha \geq 0$, for the number of paths reaching α, r times, and concerning the joint distribution of the numbers of times and steps in the region to the right of α. The last is shown to lead to a result connected with a ballot theorem of L. Takács [**T**]. The author mentions also related results due to E. Csáki [**C0**], E. Csáki & I. Vincze [**C3, C4**], K. Sen [**Se**] and O. Engleberg [**E**]. *C.J. Ridler-Rowe*]

Po. G. Pólya, On the number of certain lattice polygons, *J. Combin. Theory* **6** (1969) 102-105; MR **38** #4329.

[A closed polygon without double points that consists of segments of length one joining neighboring lattice points is called a lattice polygon. Two lattice polygons are considered as not different if and only if there exists a parallel translation superposing one to the other. The number of ``different lattice polygons'' is indicated by dlp. A closed plane curve without double points is termed convex with respect to the direction d if for the intersection of the closed domain surrounded by the curve with any straight line of direction d, only three cases are possible: The intersection is either the

empty set, or consists of just one point or of just one segment. A curve is convex in the usual sense if and only if it is convex with respect to all directions [a square is not convex under this strict definition -- RKG].

Let a_m denote the number of dlp convex with respect to the vertical direction with area *m*, b_n the number of dlp convex with respect to the $-45°$ direction with perimeter 2*n*, and c_{mn} the number of dlp convex with respect to the $-45°$ direction with area *m* and perimeter 2*n*; evidently $\sum_m c_{mn} = b_n$. In this paper explicit expressions are given for the numbers a_m, b_n and c_{mn}. For example,
$\sum_1^\infty a_m x^m = x + 2x^2 + 6x^3 + 19x^4 + 61x^5 + \ldots = x(1-x)^3/(1-5x+7x^2-4x^3)$,
$b_n = (1/(4n-2))\binom{2n}{n}$. The proofs of the results stated will be presented in a subsequent paper. *A.L. Whiteman*]

R1. Don Rawlings, The Euler-Catalan identity, *European J. Combin.*, **9** (1988) 53-60; MR **89g**:05017.

[This paper is an attempt to unify the various generalizations of Catalan and Eulerian numbers by using *q*-theory. The author denotes the generating function for permutations by descents, major index, inversions and patterns by

$$(*) \qquad A(n; t, q, p, u, v) = \sum_{\sigma \in s} t^{d(\sigma)} q^{m(\sigma)} p^{i(\sigma)} u^{a(\sigma)} v^{b(\sigma)}.$$

Denoting $A_n(t) = A(n; t, q, p, u, v)$, the author shows that the recurrence

$$(**) \quad A_{n+1}(t) = A_n(tq) + t \sum_{k=1}^{n} q^k p^k u^{k(n-k)} \begin{bmatrix} n \\ k \end{bmatrix} A_k(t) A_{n-k}(tq^{k+1})$$

holds. Defining *C*(*n*;*t*,*q*,*p*)=*A*(*n*;*t*,*q*,*p*,0,1) and *K*(*n*;*t*,*q*,*p*)=*A*(*n*;*t*,*q*,*p*,1,0), the author deduces recurrences for *C* and *K* from

which two classic *q*-Catalan numbers defined by **Ca** follow by taking $t = q = 1$. Taking $u = 1$, $v = 1$ in (**) leads to a new recurrence involving $E(n;t,q,p) = A(n;t,q,p,1,1)$ which defines generalized Eulerian numbers. A conjecture involving the *q*-Catalan numbers is posed at the end of Section 5. *R.N. Kalia*]

Se. Kanwar Sen, On some combinatorial relations concerning the symmetric random walk, *Magyar Tud. Akad. Mat. Kutató Int. Közl.*, **9** (1964), 335-357; MR **33** #6715.

[The author considers sequences $(\vartheta_1, \vartheta_2, \ldots \vartheta_{2n})$ of $n+k$ 1's and $n-k$ -1's, in other words the polygonal paths from (0,0) to $(2n,2k)$ through the points (i, s_i) with $s_i = \vartheta_1 + \vartheta_2 + \ldots + \vartheta_i$ in a rectangular coordinate-system, where each possible array (path) has the same probability. In connexion with this restricted random walk, there are joint distribution laws and joint limiting distribution laws determined ofr the number of intersections (number of changes of sign of the s_i) and the number of positive steps, as well as for the number of intersections at the height r (the number of changes of sign of $s_i - r$) and the number of steps above the height r. Applying the results obtained, the author proves some known relations for the unrestricted case also. The proofs of the theorems are of a combinatorial character, some of them involving one-to-one correspondences of paths. The paper has some points in common with **E.** *I. Vincze*]

Sh. Louis W. Shapiro, A lattice path lemma and an application in enzyme kinetics, *J. Statist. Plann. Inference* **14** (1986) 115-122; MR **87j**:05021.

[Consider the rectangular lattice from (0,0) to (a,b). Choose z integers $1 \le a_1 < a_2 < \ldots < a_z \le a$ and z integers $1 \le b_1 < b_2 < \ldots < b_z \le b$, and place stones on the squares (a_1, b_1), ..., (a_z, b_z). The author first shows that if the integers are chosen randomly, and a random path from (0,0) to (a,b) with unit steps east and north is chosen, then the probability that the path passes beneath all the stones is $1/(z+1)$.

The author next considers a model for enzyme kinetics closely related to that studied by **Hi** and by **SZ**. In these models the states are all 0-1 sequences of length M. Each 0 or 1 represents an enzyme, which is either reduced (1) or oxidized (0). The transition rules essentially allow a 01 subsequence to become 10. Using the result of the first part of the paper, the author computes the steady-state distribution under transition probabilities which are different from those used in the earlier papers. *Ira Gessel*]

Su. Robert A. Sulanke, A recurrence restricted by a diagonal condition: generalized Catalan numbers, *Fibonacci Quart.*, **27** (1989) 33-46; MR **90c**:05012.

[This paper contains a proof via lattice paths of the Lagrange inversion theorem for ordinary generating functions. It also includes many examples of the Catalan-Motzkin-Schröder sequence variety. A translation from lattice paths to planar trees is given along with several planar tree examples.

Basically this paper considers paths where each step is of the form $(x,y) \to (x+j, y+1)$, $j \in \{0,1,2,\ldots\}$. Such a path from (0,0) to (*k*,*l*) is good if after leaving (0,0) all points on the path must lie above the line $y = \mu x$, $\not\in$.

The number of good paths from (0,0) to $(k\mu + d)$ [sic!] is shown to be $d/(1+k\mu)$ of all paths between the same points. These paths are then weighted and generating functions are introduced, leading, eventually, to a combinatorial proof of the Lagrange inversion theorem.

Other combinatorial proofs include those of **Ra** (ordinary generating functions), **L** (exponential generating functions) and **G**. *Louis Shapiro*]

T1. Lajos Takács, Ballot problems, *Z. Wahrscheinlichkeitstheorie und verw. Gebiete*, **1** (1962) 154-158; MR **26** #3131.

[The author proves a discrete variant of Spitzer's lemma, to the effect that $P\{\Delta_n = j | \nu_1 + \ldots + \nu_n = 1\} = 1/n$, where Δ_n is the number of positive partial sums $\nu_1 + \ldots + \nu_m$, $(m \le n)$ and the ν_i are integer-valued with permutation-symmetric distribution. He uses this to prove that, if all possible voting sequences are equally likely and the two candidates get *a* and *b* votes with (*a*,*b*) = 1, and if $\Delta^*_{a,b}$ denotes the number of the *a*+*b* vote-count times when the ratio of votes is $\ge a/b$, then $P\{\Delta^*_{a,b} = j\} = 1/(a+b)$. The probability that the amount by which the first candidate is ahead stays strictly between *c*-*d* and *c*, where *c* and *d* are positive integers, *c* < *d*, and *c*-*d* < *b*-*a* < *c*, is shown to be

$$\binom{a+b}{a}^{-1} \sum_k \left[\binom{a+b}{a-kd} - \binom{a+b}{a+c+kd} \right].$$

The results extend those of many authors, some of the more recent being Chung, Feller, Hodges, Gnedenko, Rvaöeva. *J. Kiefer*]

T2. Lajos Takács, The distribution of majority times in a ballot, *Z. Wahrscheinlichkeitstheorie und verw. Gebiete*, **2** (1963) 118-121; MR **28** #3490.

[In this sequel to a previous paper [**T1**] further probabilities are calculated concerning the number of times one candidate leads over another during the successive stages of a ballot. The combinatorial proofs are based on lemmas which are relevant also to fluctuation theory, order statistics and the theory of queues. The author also gives a generalization to processes with independent increments. *F.L. Spitzer*]

Ta. Lajos Takács, Some asymptotic formulas for lattice paths, *J. Statist. Plann. Inference* **14** (1986) 123-142; MR **87k**:60082.

[The author proves asymptotic formulas for the area under lattice paths starting at (0,0) with unit steps in the positive *x*- and *y*-directions. Two of the simpler formulas are as follows.

Let $\theta(n)$ be the area under a random path of length *n*. Then

$$\lim_{n\to\infty}\left[\frac{n^{3/2}}{\sqrt{48}}P\{\theta(n)=j\}-\phi\left(\frac{\sqrt{48}(j-\frac{1}{8}n^2)}{n^{3/2}}\right)\right]=0$$

uniformly in *j* for *j*=0, 1, ..., $\lfloor\frac{1}{2}n^2\rfloor$, where $\phi(x)=e^{-x^2/2}/\sqrt{2\pi}$.

Let $\phi(a,b)$ be the area under a random path from (0,0) to (*a*,*b*). Then

$$\lim_{\substack{a\to\infty\\ b\to\infty}}\left[\sigma_{a,b}P\{\theta(a,b)=j\}-\phi\left(\frac{j-\frac{1}{2}ab}{\sigma_{ab}}\right)\right]=0$$

uniformly in *j* for $|j-\frac{1}{2}ab|\geq\sigma_{a,b}\epsilon$, where ϵ is a positive real number and $\sigma_{a,b}=\sqrt{ab(a+b+1)/12}$.

Let *w*(*n*,*j*) be the number of lattice paths from (0,0) to (*n*,*n*) with area *j* which stay below the line *y* = *x* for 0 < *x* < *n*. Let C_n be the Catalan number $(1/(n+1))\binom{2n}{n}$, and let η_n be the discrete random variable whose probability distribution is given by $P\{\eta_n=j\}=w(n,\binom{n}{2}-j)/C_{n-1}$. The author gives empirical evidence that suggests

$$P\left\{\frac{a\eta_n}{\left(\frac{4^n}{8C_{n-1}}-\frac{n}{2}\right)}\leq x\right\}\approx\frac{1}{\Gamma(a)}\int_0^x e^{-u}u^{a-1}\,du,$$

where $a=3\pi/(10-3\pi)$. *Ira Gessel*]

W1. Toshihiro Watanabe & Sri Gopal Mohanty, On an inclusion-exclusion formula based on the reflection principle, *Discrete Math.* **64** (1987) 281-288; MR **88d**:05012.

[**A1** first used the refexion principle to count paths in the plane, with unit steps in the positive horizontal and vertical directions, that never touch the line $x = y$. Suppose that lattice points p and q lie on the same side of this line. The number of ``good paths'' from $p$ to $q$ is the total number of paths from $p$ to $q$ minus the number of ``bad paths'' from p to q (those which touch the line). By reflecting in the line $x = y$ the segment of a bad path from its starting point to its first meeting with this line, we find that the number of bad paths from p to q is equal to the total number of paths from p' to q, where p' is the reflexion of p in $x = y$.

The authors show here how André's reflexion principle can be used to solve the multidimensional generalization of the ballot problem, which is equivalent to counting paths not touching the hyperplanes $x_i = x_j$, i, j=1, ..., n. Here all reflexions in the hyperplanes $x_i = x_j$ are used and there are $n!$ terms in the resulting formula, with alternating signs, corresponding to the $n!$ permutations of the coordinates generated by the reflexions in the hyperplanes. A similar proof was given by **Ze**; the authors' proof describes in more detail the successive reflexions applied to a path. *Ira Gessel*]

W2. Toshihiro Watanabe, On a determinant sequence in the lattice path counting, *J. Math. Anal. Appl.* **123** (1987) 401-414; MR **88g**:05015.

[The number of lattice paths connecting two given lattice points and staying between upper and lower boundaries can be expressed by a determinant involving binomial coefficients, due to G. Kreweras. The recursive nature of this problem leads to a system of difference equations, and the same type of solution (determinants involving polynomials of binomial type) applies to a much larger class of operator equations. The author makes a new approach by associating such determinants with random tableaux. He obtains determinant sequences which satisfy a convolution identity similar to sequences of binomial type. The theory is then applied to Hill's enzyme model, reproducing a result of Shapiro and Zeilberger. *Heinrich Niederhausen*] [cf. **K2, Hi, SZ**]

W3. Toshihiro Watanabe, On a generalization of polynomials in the ballot problem, *J. Statist. Plann. Inference* **14** (1986) 143-152; MR **87j**:05024.

[The ballot-polynomials $p_m(x) = ((x - \mu m)/(x + m))\binom{x+m}{m}$ are Sheffer polynomials for the backwards difference operator ∇. They are the solutions of the system of operator equations $\nabla p_m(x) = p_{m-1}(x)$, uniquely determined by the initial conditions $p_0(x) = 1$ for all x, and $p_m(\mu m) = 0$ for all $m \geq 1$. Using his earlier results on multivariate umbral calculus, the author shows how to solve the n-dimensional system $P_i(\delta)s_{\mathbf{m}}(\mathbf{x}) = s_{\mathbf{m}-\mathbf{e_i}}(\mathbf{x})$ for all i=1, ..., n, where $\{P_1(\delta), \ldots, P_n(\delta)\}$ is a delta set and $\mathbf{e_i}$ stands for the ith unit vector. The general solution for such a system is then specialized to give an n-dimensional version of the ballot polynomials.

A generalized version of the classical ballot problem, attributed to Takács, is solved by the polynomials

$$\frac{x}{x+\sum_{k=1}^{r}(\mu_k+1)n_k}\binom{x+\sum_{k=1}^{r}(\mu_k+1)n_k}{n_1,\ldots,n_r}.$$

The *n*-dimensional analog is obtained from a very general setting, leading to a so-called ``multinomial basic polynomial sequence". *Heinrich Niederhausen*]

W4. Toshihiro Watanabe, On the Littlewood-Richardson rule in terms of lattice path combinatorics, Proc. First Japan Conf. Graph Theory & Appl., *Discrete Math.* **72** (1988) 385-390; MR **90b**:05010.

[This paper gives a proof of the Littlewood-Richardson rule for multiplying Schur functions by using the characterization of Schur functions as collections of nonintersecting lattice paths. The proof is based on Robinson's recomposition rule for transforming non-lattice paths into lattice paths. *Dennis White*]

Ze. Doron Zeilberger, André's reflection proof generalized to the many-candidate ballot problem, *Discrete Math.* **44** (1983) 325-326; MR **84g**:05016.

[The *n*-candidate ballot problem is the problem of counting those lattice walks from the origin to the point $(m_1,\ldots,m_n)$, $m_1 \geq m_2 \geq \ldots \geq m_n \geq 0$, which never touch any of the hyperplanes $x_i - x_{i+1} = -1$. The problem is equivalent to that of counting Young tableaux of a given shape. D. André [**A1**] showed that for *n*=2 the answer is $\binom{m_1+m_2}{m_1} - \binom{m_1+m_2}{m_1+1}$ as follows: $\binom{m_1+m_2}{m_1}$ counts all paths from (0,0) to (m_1,m_2). If a path touches $x_1 - x_2 = -1$, reflect the initial segment up to the first such touch in this line to get a path from (-1,1) to (m_1,m_2). This gives a bijection between ``bad" paths from (0,0) to (m_1,m_2) and all paths from (-1,1) to (m_1,m_2) which proves the formula.

The author generalizes this argument to obtain the determinant formula (due to Frobenius and MacMahon) $(m_1+\ldots+m_n)!\det(1/(m_i-i+j)!)$. Here a term corresponding to a permutation π counts paths from $(1-\pi(1),\ldots,n-\pi(n))$ to $(m_1,\ldots,m_n)$. The ``bad" paths are cancelled in pairs by reflexion in the hyperplanes $x_i - x_{i+1} = -1$. A related approach, using recurrences instead of reflexion, was recently given by N. Linial [**Li**]. *Ira Gessel*]

Abstract

We show that formulae of Gessel for the generating functions for Young standard tableaux of height bounded by k (see [2]) satisfy linear differential equations, with polynomial coefficients, equivalent to P-recurrences conjectured by Favreau, Krob and the first author (see [1]) for the number of bounded height tableaux and pairs of bounded height tableaux.

1. Results

Let us first fix some notation. A partition λ of a positive integer n is a sequence of integers

$$\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_k > 0$$

such that $\sum_i \lambda_i = n$. We denote this by writing $\lambda \vdash n$, and say that k is the *height* $h(\lambda)$ of λ. The height of the empty partition (of 0) is 0. The (Ferrer's) diagram of a partition λ is the set of points $(i,j) \in \mathbf{Z}^2$ such that $1 \leq j \leq \lambda_i$. It is also denoted by λ. Clearly a partition is characterized by its diagram. The conjugate λ' of a partition λ is the partition with diagram $\{(j,i) \mid (i,j) \in \lambda\}$.

A standard Young tableau T is an injective labeling of a Ferrer's diagram by the elements of $\{1,2,\ldots,n\}$ such that $T(i,j) < T(i+1,j)$ for $1 \leq i < k$ and $T(i,j) < T(i,j+1)$ for $1 \leq j < \lambda_i$. We further say that λ is the *shape* of the tableau T. For a given λ, the number f_λ of tableaux of shape λ is given by the *hook length* formula

$$f_\lambda = \frac{n!}{\prod_c h_c},$$

where $c = (i,j)$ runs over the set of points in the diagram of λ, and

$$h_c = \lambda_i - i + \lambda'_j - j + 1.$$

Other classical results in this context are

$$\sum_{\lambda \vdash n} f_\lambda^2 = n!,$$

* With support from NSERC and FCAR.

and

$$\sum_{\lambda \vdash n} f_\lambda = \text{ coeff of } \frac{x^n}{n!} \text{ in } e^{x+x^2/2}.$$

We are interested in the enumeration of tableaux of height bounded by some integer k; that is to say we wish to compute the numbers

$$\tau_k(n) = \sum_{h(\lambda) \le k} f_\lambda$$

as well as

$$T_k(n) = \sum_{h(\lambda) \le k} f_\lambda^2.$$

For example, the first few sequences $\tau_k(n)$ for $n \ge 1$ are

$\tau_2(n) \to$ 1, 2, 3, 6, 10, 20, 35, 70, 126, 252, 462, 924, 1716, 3432, 6435, 12870, 24310, 48620, 92378, ...

$\tau_3(n) \to$ 1, 2, 4, 9, 21, 51, 127, 323, 835, 2188, 5798, 15511, 41835, 113634, 310572, 853467, ...

$\tau_4(n) \to$ 1, 2, 4, 10, 25, 70, 196, 588, 1764, 5544, 17424, 56628, 184041, 613470, 2044900, ...

$\tau_5(n) \to$ 1, 2, 4, 10, 26, 75, 225, 715, 2347, 7990, 27908, 99991, 365587, 1362310, 5159208, ...

$\tau_6(n) \to$ 1, 2, 4, 10, 26, 76, 231, 756, 2556, 9096, 33231, 126060, 488488, 1948232, 7907185, ...

(These are sequences A001405, A001006, A005817, A049401, A007579 in [5].) For $T_k(n)$, we have

$T_2(n) \to$ 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, 208012, 742900, 2674440, 9694845, ...

$T_3(n) \to$ 1, 2, 6, 23, 103, 513, 2761, 15767, 94359, 586590, 3763290, 24792705, 167078577, ...

$T_4(n) \to$ 1, 2, 6, 24, 119, 694, 4582, 33324, 261808, 2190688, 19318688, 178108704, 1705985883, ...

$T_5(n) \to$ 1, 2, 6, 24, 120, 719, 5003, 39429, 344837, 3291590, 33835114, 370531683, 4285711539, ...

$T_6(n) \to$ 1, 2, 6, 24, 120, 720, 5039, 40270, 361302, 3587916, 38957991, 457647966, 5763075506, ...

(Sequences A000108, A005802, A052397, A052398, A052399 in [5].)

In [2] Gessel deduces the following formulae from a result of Gordon:

$$y_k(x) := \sum_{n=0}^{\infty} \frac{\tau_k(n) x^n}{n!} = \begin{cases} \det\left[J_{i-j}(x) - J_{i+j-1}(x)\right]_{1 \le i,j \le k/2} & \text{if } k \text{ is even,} \\ e^x \det\left[J_{i-j}(x) - J_{i+j}(x)\right]_{1 \le i,j \le (k-1)/2} & \text{if } k \text{ is odd,} \end{cases}$$

and

$$Y_k(x) := \sum_{n=0}^{\infty} \frac{T_k(n) x^n}{(n!)^2} = \det\left[I_{i-j}(x)\right]_{1 \le i,j \le k},$$

where

$$J_k(x) = \sum_{n=0}^{\infty} \frac{x^{2\,n+k}}{n!\ (n+k)!}$$

and

$$I_k(x) = \sum_{n=0}^{\infty} \frac{x^{n+k/2}}{n!\ (n+k)!}$$

If k is positive integer, we set $J_{-k} := J_k$ and $I_{-k} := I_k$. The resulting expressions rapidly become unwieldy. For example,

$$y_2(x) = J_0(x) + J_1(x)$$

$$y_3(x) = e^x \left(J_0(x) - J_2(x)\right)$$

$$y_4(x) = J_0(x)^2 + J_0(x)\,J_1(x) + J_0(x)\,J_3(x) - J_1(x)^2 - 2\,J_1(x)\,J_2(x) + J_1(x)\,J_3(x) - J_2(x)^2$$

$$y_5(x) = e^x \left(J_0(x)^2 - J_0(x)\,J_2(x) - J_0(x)\,J_4(x) - J_1(x)^2 + 2\,J_1(x)\,J_3(x) + J_2(x)\,J_4(x) - J_3(x)^2\right)$$

$$\begin{aligned} y_6(x) = {} & J_0(x)^3 + J_0(x)^2\,J_1(x) + J_0(x)^2\,J_3(x) + J_0(x)^2\,J_5(x) - 2\,J_0(x)\,J_1(x)^2 - 2\,J_0(x)\,J_1(x)\,J_2(x) \\ & + J_0(x)\,J_1(x)\,J_3(x) - 2\,J_0(x)\,J_1(x)\,J_4(x) + J_0(x)\,J_1(x)\,J_5(x) - 2\,J_0(x)\,J_2(x)^2 \\ & - 2\,J_0(x)\,J_2(x)\,J_3(x) - J_0(x)\,J_3(x)^2 + J_0(x)\,J_3(x)\,J_5(x) - J_0(x)\,J_4(x)^2 - J_1(x)^3 \\ & + 2\,J_1(x)^2\,J_2(x) + 2\,J_1(x)^2\,J_3(x) - 2\,J_1(x)^2\,J_4(x) - J_1(x)^2\,J_5(x) + 2\,J_1(x)\,J_2(x)^2 \\ & + 2\,J_1(x)\,J_2(x)\,J_3(x) + 2\,J_1(x)\,J_2(x)\,J_4(x) - 2\,J_1(x)\,J_2(x)\,J_5(x) + 2\,J_1(x)\,J_3(x)\,J_4(x) \\ & + J_1(x)\,J_3(x)\,J_5(x) - J_1(x)\,J_4(x)^2 - J_2(x)^2\,J_3(x) + 2\,J_2(x)^2\,J_4(x) - J_2(x)^2\,J_5(x) \\ & - 2\,J_2(x)\,J_3(x)^2 + 2\,J_2(x)\,J_3(x)\,J_4(x) - J_3(x)^3 \end{aligned}$$

We can simplify these using properties of Bessel functions. Recalling the easily deduced relations

$$J_k(x) = J_{k-2}(x) - \frac{1}{x}(n-k-1)\,J_{k-1}(x), \qquad k \geq 2,$$

we get, after some computation, the much simpler expressions

$$y_3(x) = x^{-1} e^x\,J_1(x)$$

$$y_4(x) = x^{-2}\,\left(-2\,x\,J_0(x)^2 + 2\,J_0(x)\,J_1(x) + (2\,x+1)\,J_1(x)^2\right)$$

$$y_5(x) = x^{-4} e^x \left(-4\,x^2\,J_0(x)^2 + 2\,x\,J_0(x)\,J_1(x) + 2\,\left(2\,x^2+1\right) J_1(x)^2\right)$$

$$\begin{aligned} y_6(x) = {} & x^{-6} \left(-4\,x^2\,(4\,x-3)\,J_0(x)^3 - 4\,x\,\left(4\,x^2 - 3\,x + 6\right) J_0(x)^2\,J_1(x) \right. \\ & \left. + 4\,\left(4\,x^3 - x^2 + 3\right) J_0(x)\,J_1(x)^2 + 4\,\left(4\,x^3 - x^2 + 5\,x + 1\right) J_1(x)^3\right) \end{aligned}$$

Similarly

$$Y_2(x) = I_0(x)^2 - I_1(x)^2$$

$$Y_3(x) = x^{-1} \left(2\,\sqrt{x}\,I_0(x)^2\,I_1(x) - I_0(x)\,I_1(x)^2 - 2\,\sqrt{x}\,I_1(x)^3\right)$$

$$\begin{aligned} Y_4(x) = {} & x^{-3} \big(- 4\,x^2\,I_0(x)^4 + 8\,x\,\sqrt{x}\,I_0(x)^3\,I_1(x) + 4\,x\,(2\,x-1)\,I_0(x)^2\,I_1(x)^2 \\ & - 8\,x\,\sqrt{x}\,I_0(x)\,I_1(x)^3 - x\,(4\,x-1)\,I_1(x)^4\big) \end{aligned}$$

A theoretical argument (see [2]) shows that the generating functions $y_k(x)$ and $Y_k(x)$ are *D-finite*. That is to say, they satisfy linear differential equations with polynomial coefficients. In fact, it is well known and classical that one can translate such linear differential equations into recurrences with polynomial coefficients. More precisely, a *P-recurrence* for a sequence a_n is one of the form

$$p_0(n)\,a_n + p_1(x)\,a_{n-1} + \ldots + p_k(n)\,a_{n-k} = q(n),$$

where all $p_i(n)$, $1 \leq i \leq k$, and $q(n)$ are polynomials in n. We say that a sequence is P-recursive if it satisfies a P-recurrence. The class of P-recursive sequences is closed under point-wise products. Since $1/n!$ is easily seen to be P-recursive, it follows that, if a_n is P-recursive, then so are $a_n/n!$ and $a_n/n!^2$. The algorithmic

translation from D-finite to P-recursive (and back) has been implemented in the package GFUN in Maple (see [4]), which also contains many other nice tools for handling recurrences and generating functions.

Computer experiments made by Krob, Favreau and the first author led to conjectures (see [1]) for an explicit form for P-recurrences for $\tau_h(n)$ and $T_h(n)$. These conjectures can be easily (and automatically) reformulated as linear differential equations for $y_k(x)$ and $Y_k(x)$. We first observe that it is not hard to show the existence of a linear differential equation of order bounded by

$$\ell(k) := \left\lfloor \frac{k}{2} \right\rfloor + 1$$

with polynomial coefficients, admitting $y_k(x)$ as a solution. In fact, this follows readily from the following proposition.

Proposition 1. *Let $\mathcal{V}_k$ denote the vector space over the field $\mathbf{C}(x)$ of rational functions in x spanned by $y_k(x)$ and all its derivatives. Then*

$$\dim \mathcal{V}_k \le \ell(k).$$

Proof. Setting $n := \ell(k) - 1$, it is clear from our previous discussion that y_k lies in the span $\mathcal{W}_k$ of the set of $\ell(k)$ elements given by

$$\{ J_0(x)^m \, J_1(x)^{n-m} \mid 0 \le m \le n \}$$

if k is even, and by

$$\{ e^x \, J_0(x)^m \, J_1(x)^{n-m} \mid 0 \le m \le n \}$$

if k is odd. $\mathcal{W}_k$ is clearly closed under differentiation, since we easily see that

$$\begin{aligned} \frac{d}{dx} J_0(x) &= 2\, J_1(x), \\ \frac{d}{dx} J_1(x) &= 2\, J_0(x) - \frac{1}{x}\, J_1(x), \end{aligned} \tag{1}$$

from which we deduce that

$$\frac{d}{dx} J_0(x)^a \, J_1(x)^b = \frac{2\,a}{x} \, J_0(x)^{a-1} \, J_1(x)^{b+1} \, x + 2\,b \, J_0(x)^{a+1} \, J_1(x)^{b-1} - \frac{b}{x} \, J_0(x)^a \, J_1(x)^b, \tag{2}$$

as well as a similar expression for the derivative of $e^x \, J_0(x)^a \, J_1(x)^b$. Thus $\mathcal{V}_k$ is contained in $\mathcal{W}_k$, and hence its dimension is bounded by $\ell(k)$. ∎

Setting for the moment $n := \ell(k)$ and $y := y_k(x)$, it clearly follows from the above proposition that

$$y,\ y',\ y'',\ \ldots\ , y^{(n)}$$

are linearly dependent, hence $y_k(x)$ satisfies a homogeneous linear differential equation of order (at most) $\ell(k)$ with polynomial coefficients (in x). However, it appears that a stronger result holds.

Conjecture (Bergeron–Favreau–Krob, [1]). For each k, there are polynomials $p_m(x)$ of degree at most $\ell - 1$ such that $y_k(x)$ is a solution of

$$\sum_{m=0}^{\ell} p_m(x) y^{(m)} \ = \ 0,$$

where $\ell = \ell(k)$. Moreover, for $m \ge 1$, $p_m(x) = q_m(x)\, x^{m-1}$, and $p_\ell(x) = x^{\ell-1}$.

The first few cases for $y_k(x)$ are*

* Here $\to$ means "is a solution of".

$$y_2(x) \;\to\; x\,y'' + 2\,y' - 2\,(2\,x+1)\,y = 0$$

$$y_3(x) \;\to\; x\,y'' - (2\,x-3)\,y' - 3\,(x+1)\,y = 0$$

$$y_4(x) \;\to\; x^2\,y''' + 10\,x\,y'' - 4\,\left(4\,x^2+2\,x-5\right)y' - 4\,(8\,x+5)\,y = 0$$

$$y_5(x) \;\to\; x^2\,y''' - (3\,x-13)\,x\,y'' - \left(13\,x^2+26\,x-35\right)y' + 5\,\left(3\,x^2-7\,x-7\right)y = 0$$

Equating coefficients of $x^n/n!$ on both hand sides of these differential equations, one finds that they are equivalent to the recurrences

$$(n+1)\,\tau_2(n) - 2\,\tau_2(n-1) - 4\,(n-1)\,\tau_2(n-2) = 0$$

$$(n+2)\,\tau_3(n) - (2\,n+1)\,\tau_3(n-1) - 3\,(n-1)\,\tau_3(n-2) = 0$$

$$(n+3)\,(n+4)\,\tau_4(n) - 16\,(n-1)\,\tau_4(n-2)\,n - (8\,n+12)\,\tau_4(n-1) = 0$$

$$(n+4)\,(n+6)\,\tau_5(n) - \left(3\,n^2+17\,n+15\right)\tau_5(n-1) - (n-1)(13\,n+9)\,\tau_5(n-2) + 15\,(n-1)\,(n-2)\,\tau_5(n-3) = 0$$

Up to now, only these recurrences (that is, for $k \le 5$), had been implicitly known (see [3]). However, using the simplified expressions for $y_k(x)$ given here, and a reformulation in term of linear differential equations (with the help of GFUN [4]) we have been able to check (in the form of a computer algebra proof) that the conjecture above is true for $k \le 11$, from which it follows that the corresponding recurrences hold. This computer verification simply uses the derivation rules (1) for $J_0(x)$ and $J_1(x)$ to simplify the expressions obtained by substitution of Gessel's formulae in the following differential equations.

$$\begin{aligned} y_6(x) \;\to\; & x^3\,y^{(4)} + 28\,x^2\,y''' - 10\,\left(4\,x^2+2\,x-23\right)x\,y'' \\ & - 4\,\left(108\,x^2+61\,x-135\right)y' + 36\,(2\,x+5)\,\left(2\,x^2-3\,x-3\right)y = 0 \end{aligned}$$

$$\begin{aligned} y_7(x) \;\to\; & x^3\,y^{(4)} - 2\,(2\,x-17)\,x^2\,y''' - \left(34\,x^2+102\,x-343\right)x\,y'' \\ & + \left(76\,x^3-450\,x^2-686\,x+1001\right)y' + 7\,\left(15\,x^3+74\,x^2-143\,x-143\right)y = 0 \end{aligned}$$

$$\begin{aligned} y_8(x) \;\to\; & x^4\,y^{(5)} + 60\,x^3\,y^{(4)} - 2\,\left(40\,x^2+20\,x-619\right)x^2\,y''' - 4\,\left(608\,x^2+331\,x-2567\right)x\,y'' \\ & + 8\,\left(128\,x^4+128\,x^3-2480\,x^2-1527\,x+3536\right)y' + 128\,\left(64\,x^3+72\,x^2-286\,x-221\right)y = 0 \end{aligned}$$

$$\begin{aligned} y_9(x) \;\to\; & x^4\,y^{(5)} - 5\,(x-14)\,x^3\,y^{(4)} - \left(70\,x^2+280\,x-1693\right)x^2\,y''' \\ & + \left(230\,x^3-2492\,x^2-5079\,x+16535\right)x\,y'' \\ & + \left(789\,x^4+5544\,x^3-24073\,x^2-33070\,x+53865\right)y' \\ & - 27\,\left(35\,x^4-274\,x^3-1017\,x^2+1995\,x+1995\right)y = 0 \end{aligned}$$

$$\begin{aligned} y_{10}(x) \;\to\; & x^5\,y^{(6)} + 110\,x^4\,y^{(5)} - 2\,\left(70\,x^2+35\,x-2269\right)x^3\,y^{(4)} \\ & - 4\,\left(2268\,x^2+1211\,x-21752\right)x^2\,y''' \\ & + 4\,\left(1036\,x^4+1036\,x^3-48033\,x^2-27900\,x+191477\right)x\,y'' \\ & + 8\,\left(14300\,x^4+15542\,x^3-185404\,x^2-121352\,x+303875\right)y' \\ & - 200\,\left(72\,x^5+108\,x^4-3262\,x^3-3987\,x^2+14960\,x+12155\right)y = 0 \end{aligned}$$

$$
\begin{aligned}
y_{11}(x) \;\to\; & x^5\,y^{(6)} - (6\,x-125)\,x^4\,y^{(5)} - \left(125\,x^2+625\,x-5873\right)x^3\,y^{(4)} \\
& + 2\,\left(270\,x^3-4611\,x^2-11746\,x+64252\right)x^2\,y''' \\
& + \left(3319\,x^4+30166\,x^3-223422\,x^2-385512\,x+1293125\right)x\,y'' \\
& - \left(7734\,x^5-104329\,x^4-493828\,x^3+1987124\,x^2+2586250\,x-4697275\right)y' \\
& - 11\,\left(945\,x^5+11343\,x^4-62023\,x^3-204012\,x^2+427025\,x+427025\right)y = 0
\end{aligned}
$$

However, these verifications rapidly become (computer) time consuming. For example, with $k = 11$, we have to substitute in this last differential equation the following expression

$$
\begin{aligned}
y_{11}(x) = \frac{138240\,e^x}{x^{25}}\Big(& -14\left(32\,x^6+177\,x^4+198\,x^2-72\right)x^5\,J_0(x)^5 \\
& + 8\,\left(16\,x^8+256\,x^6+825\,x^4+585\,x^2-495\right)x^4\,J_1(x)\,J_0(x)^4 \\
& + 4\,\left(192\,x^8+833\,x^6+495\,x^4+135\,x^2+1440\right)x^3\,J_1(x)^2\,J_0(x)^3 \\
& - \left(256\,x^{10}+3648\,x^8+10799\,x^6+9690\,x^4+1980\,x^2+3600\right)x^2\,J_1(x)^3\,J_0(x)^2 \\
& - 5\,\left(64\,x^{10}+190\,x^8-77\,x^6+114\,x^4+504\,x^2-144\right)x\,J_1(x)^4\,J_0(x) \\
& + \left(128\,x^{12}+1632\,x^{10}+4557\,x^8+5482\,x^6+4158\,x^4+2052\,x^2+72\right)J_1(x)^5\Big)
\end{aligned}
$$

and simplify. Clearly we could go on to larger cases, but the point seems to be made that the conjectures are reasonable.

Similar considerations for the enumeration of pairs of tableaux, with the following differential equations, settle the corresponding conjectures for the cases $k \le 7$:

$$
Y_2(x) \;\to\; x^2\,y''' + 4\,x\,y'' - 2\,(2\,x-1)\,y' - 2\,y = 0
$$

$$
Y_3(x) \;\to\; x^3\,y^{(4)} + 10\,x^2\,y''' - (10\,x-23)\,x\,y'' - (32\,x-9)\,y' + 9\,(x-1)\,y = 0
$$

$$
\begin{aligned}
Y_4(x) \;\to\; & x^4\,y^{(5)} + 20\,x^3\,y^{(4)} - 2\,(10\,x-59)\,x^2\,y''' - 2\,(91\,x-110)\,x\,y'' \\
& + 4\,\left(16\,x^2-87\,x+20\right)y' + 16\,(8\,x-5)\,y = 0
\end{aligned}
$$

$$
\begin{aligned}
Y_5(x) \;\to\; & x^5\,y^{(6)} + 35\,x^4\,y^{(5)} - 7\,(5\,x-59)\,x^3\,y^{(4)} - 2\,(336\,x-979)\,x^2\,y''' + \left(259\,x^2-3650\,x+3383\right)x\,y'' \\
& + \left(1917\,x^2-5708\,x+1225\right)y' - 25\,\left(9\,x^2-93\,x+49\right)y = 0
\end{aligned}
$$

$$
\begin{aligned}
Y_6(x) \;\to\; & x^6\,y^{(7)} + 56\,x^5\,y^{(6)} - 28\,(2\,x-41)\,x^4\,y^{(5)} - 4\,(483\,x-2684)\,x^3\,y^{(4)} \\
& + 4\,\left(196\,x^2-5480\,x+11543\right)x^2\,y''' + 8\,\left(1686\,x^2-11941\,x+9830\right)x\,y'' \\
& - 4\,\left(576\,x^3-14931\,x^2+34438\,x-7290\right)y' - 72\,\left(144\,x^2-821\,x+405\right)y = 0
\end{aligned}
$$

$$
\begin{aligned}
Y_7(x) \;\to\; & x^7\,y^{(8)} + 84\,x^6\,y^{(7)} - 42\,(2\,x-65)\,x^5\,y^{(6)} - 2\,(2352\,x-21881)\,x^4\,y^{(5)} \\
& + 3\,\left(658\,x^2-31606\,x+121455\right)x^3\,y^{(4)} + 2\,\left(31986\,x^2-424260\,x+754183\right)x^2\,y''' \\
& - \left(12916\,x^3-648834\,x^2+3329230\,x-2610671\right)x\,y'' \\
& - \left(175704\,x^3-2292734\,x^2+4684008\,x-1002001\right)y' \\
& + 49\,\left(225\,x^3-9630\,x^2+42313\,x-20449\right)y = 0
\end{aligned}
$$

Introduction

When one looks up the sequence 1, 6, 31, 160, 856, 4802, 28 337, 175 896, ... in one of Sloane's integer sequence identifiers [HIS, EIS, OIS], one learns that these numbers are the numbers of driving-point impedances of an n-terminal network for $n = 2, 3, 4, 5, 6, 7, 8, 9, \ldots$ as described in an old article by Riordan [Ri].

In combinatorics there are two common ways of generalizing classical enumerative facts. One such generalization arises by replacing the set $[n] = \{1, \ldots, n\}$ by an n-dimensional vector space over the finite field $\mathbb{F}_q$ to get a q-analogue. The other generalization or extension is by considering "B- and D-analogues" of an "A-case". This terminology stems from Lie theory. (There is no "C-case" here since it coincides with

the "B-case".) Of course one may try to combine the two approaches and supply q-B- and q-D-analogues.

In this note I shall describe B- and D-analogues of the numbers of driving-point impedances of an n-terminal network. To assuage any possible curiosity about how these sequences look, here are their first few terms:

B-analogue	1, 8, 58, 432, 3396, 28 384, 252 456, 2 385 280, ...
D-analogue	0, 4, 31, 240, 1931, 16 396, 147 589, 1 408 224, ...

I should probably emphasize that I will only give mathematical arguments and will not attempt to provide a physical realization of B- and D-networks.

We start from certain classical hyperplane arrangements. A hyperplane arrangement defines a family of subspaces, namely those subspaces which can be written as intersections of some of the hyperplanes in the arrangement. For each such subspace we will choose a normal form that represents the subspace. Such a normal form consists of an equivalence class of partial $\{\pm 1\}$-partitions in the terminology of Dowling [Do]. Dowling actually constructed G-analogues of the partition lattices for any finite group G. Using the concept of voltage graphs (or signed graphs for $|G| = 2$) or more generally biased graphs, Zaslavsky gave a far-reaching generalization of Dowling's work. It is amusing to see that not only the network but also the mathematical treatment of hyperplane arrangements carries a graph-theoretical flavour. Here we will stick to the normal form and not translate things into the framework of graph theory, despite the success this approach has had for example in [BjSa]. In some sense the normal form approach pursues a strategy opposite to that of Zaslavsky's graphs.

Whitney numbers and characteristic polynomials for hyperplane arrangements or more generally for subspace arrangements, that is, the numbers of vertices with fixed rank in the Hasse diagrams and the Möbius functions, have been studied by many authors. Apparently little attention has been paid so far to the numbers of edges in the Hasse diagrams.

There is another point worth mentioning. It concerns a dichotomy among the A-, B-, and D-series. We will see that everything is very easy for the first two series whereas for the D-series we must work a little harder. Such a dichotomy between the A- and B-series on the one hand and the D-series on the other also occurs in other contexts, e. g., in the problem of counting reduced decompositions of the longest element in the corresponding Coxeter groups (see [St] for the initial paper). In contrast, in the Lie theory one has a different dichotomy,

namely, between the simply laced (like A and D) and the non-simply-laced (like B and C) types.

Finally, an obvious generalization, which, however, we do not go into, concerns hyperplane arrangements for the infinite families of unitary reflection groups.

Hyperplane arrangements and their intersection lattices

Let $\mathcal{A} = \{H_1, \dots, H_N\}$ be a collection of subspaces of codimension 1 in the vector space $\mathbb{R}^n$. We let $L(\mathcal{A})$ denote the poset of all intersections $H_{i_1} \cap \cdots \cap H_{i_r}$, ordered by reverse inclusion. This poset $L(\mathcal{A})$ is actually a geometric lattice. Its bottom element $\widehat{0}$ is the intersection over the empty index set, i. e., $\mathbb{R}^n$. The atoms are the hyperplanes $H_1, \dots, H_N$, and the top element $\widehat{1}$ is $H_1 \cap \cdots \cap H_N$. For many further details the reader is referred to Cartier's Bourbaki talk [Ca], Björner's exposition [Bj] for more general subspace arrangements, and the monograph by Orlik and Terao [OT] for a thorough exposition of the theory.

A theorem due to Orlik and Solomon states that for a finite irreducible Coxeter group W with Coxeter arrangement $\mathcal{A} = \mathcal{A}(W)$ we have the equality

$$|\mathcal{A}^H| = |\mathcal{A}| + 1 - h \tag{1}$$

where $H \in \mathcal{A}$ is any hyperplane of the arrangement, h is the Coxeter number of W, and $\mathcal{A}^H$ is the hyperplane arrangement in H with the hyperplanes $H \cap H'$ for $H' \in \mathcal{A} - \{H\}$. In other words, (1) says that each atom in the intersection lattice $L(\mathcal{A})$ is covered by $|\mathcal{A}| + 1 - h$ elements. One may wonder what can be said about the number of elements that cover an arbitrary element in $L(\mathcal{A})$.

The intersection lattices that concern us here come from the following hyperplanes in $\mathbb{R}^n$.

type of $\mathcal{A}$	elements of $\mathcal{A}$
$(\mathsf{A}_1)^n$	$\{x_a = 0\}_{a=1,\dots,n}$
A_{n-1}	$\{x_b = x_c\}_{1 \leqslant b < c \leqslant n}$
B_n	$\{x_a = 0\}_{a=1,\dots,n}$, $\{x_b = x_c\}_{1 \leqslant b < c \leqslant n}$, $\{x_b = -x_c\}_{1 \leqslant b < c \leqslant n}$
D_n	$\{x_b = x_c\}_{1 \leqslant b < c \leqslant n}$, $\{x_b = -x_c\}_{1 \leqslant b < c \leqslant n}$

Note that $\bigcap_{H \in \mathcal{A}} H$ is the line $x_1 = \cdots = x_n$ for type A_{n-1} (so the rank is $n-1$ in this case if $n > 0$) whereas for the other types the hyperplanes only meet in the zero vector. We agree to let A_{-1} denote the empty hyperplane arrangement in 0. So the intersection lattices for A_{-1} and

A_0 are isomorphic. Also there is a slight abuse of notation for type A_1 because it can be considered as $(\mathsf{A}_1)^1$ or as A_{2-1}. But this will not cause trouble.

For each subspace $E \in L(\mathcal{A})$ we define the subset $B_E \subseteq [n] = \{1, \ldots, n\}$ by the property that

$$C_E := \bigcap_{a \in [n]-B_E} \{x_a = 0\}$$

is the smallest intersection of coordinate hyperplanes that contains E. For instance if $\mathcal{A}$ is of type A_{n-1}, we have $B_E = [n]$ for all $E \in L(\mathcal{A})$. For the hyperplane $E = \{x_1 = x_2\} \cap \{x_2 = x_3\} \cap \{x_1 = -x_3\} \cap \{x_4 = x_7\} \cap \{x_5 = x_8\} \cap \{x_8 = 0\} \subseteq \mathbb{R}^8$ we get $B_E = \{4, 6, 7\}$.

Regarded as a subspace of C_E, E is described by a partition of B_E together with a function $\zeta : B_E \to \{\pm 1\}$. If $\{B_1, \ldots, B_k\}$ is a partition of B_E into k blocks, then E is the k-dimensional subspace

$$E = \big\{(x_1, \ldots, x_n) \in C_E \;\big|\; b, c \in B_j \text{ for some } j \Longrightarrow \zeta(b)\, x_b = \zeta(c)\, x_c\big\}.$$

Clearly, the correspondence between E and $\big(\{B_1, \ldots, B_k\}, \zeta\big)$ is 1 to 2^k because for each block there is a choice of sign.

This correspondence gives us a convenient notation for the subspaces in $L(\mathcal{A})$. We write down a partition of some $B \subseteq [n]$ and decorate the numbers $a \in B$ with $\zeta(a) = -1$ with an overbar. Having the possibility of choosing an overall sign for each block, we agree that the smallest number in each block does not have an overbar. As an example take the Coxeter arrangement of type B_3. There are 24 subspaces to be considered. Their representations as "signed permutations" are shown in the vertices (boxes) of the following Hasse diagram.

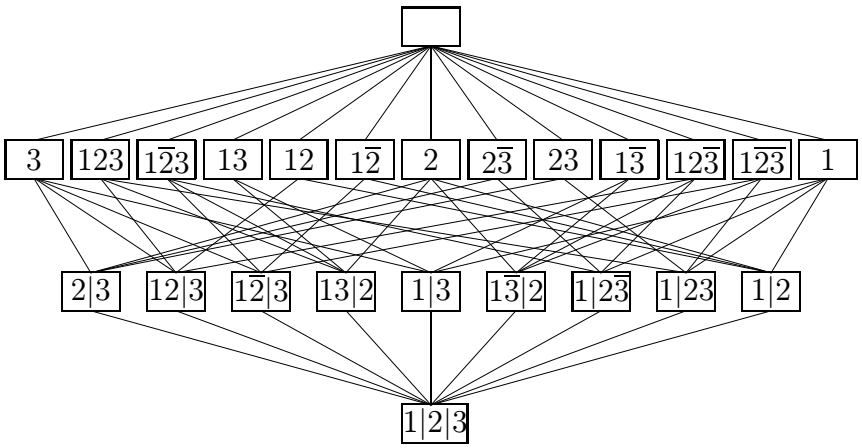

FIGURE 1. Hasse diagram of the B_3 lattice

For instance 3 stands for the line $x_1 = x_2 = 0$, $1\overline{2}3$ is for $x_1 = -x_2 = x_3$, $1|2\overline{3}$ denotes the plane $x_2 = -x_3$, $1|2$ means $x_3 = 0$ etc.

Vertices in the Hasse diagrams

Lemma 1. *For a partition $\{B_1, \dots, B_k\}$ of a subset $B \subseteq [n]$ and a function $\zeta : B \to \{\pm 1\}$ the k-dimensional subspace*

$$\left\{ (x_1, \dots, x_n) \in \mathbb{R}^n \;\middle|\; \begin{array}{l} a \in [n] - B \implies x_a = 0 \\ b, c \in B_j \text{ for some } j \implies \zeta(b)\, x_b = \zeta(c)\, x_c \end{array} \right\}$$

belongs to $L(\mathcal{A})$ according to the following table.

type of $\mathcal{A}$	condition
$(\mathsf{A}_1)^n$	$\lvert B\rvert = k$, $\zeta = 1$
A_{n-1}	$B = [n]$, $\zeta = 1$
B_n	—
D_n	$\big\lvert [n] - B \big\rvert \neq 1$

Proof. The conditions in the table above should be clear. For the types $(\mathsf{A}_1)^n$ and A_{n-1} we put $\zeta = 1$ for simplicity (literally, ζ must only be constant on each block B_j). The condition for D_n simply takes into account that the hyperplanes $x_a = 0$ do not belong to $L(\mathcal{A})$. But for instance $x_1 = \cdots = x_r = 0$ for $r \geqslant 2$ can be written as $x_1 = -x_2$, $x_1 = \cdots = x_r$ and hence this subspace is an element of $L(\mathcal{A})$. □

For integers $n, k \geqslant 0$ and $b > 0$ let $S_b(n, k)$ denote the number of partitions of $[n]$ into k blocks each containing at least b elements. So $S_1(n, k) = S(n, k)$ is a Stirling number of the second kind. Besides $b = 1$ we shall only need the case where $b = 2$, which one knows from Pólya-Szegő [PS, Part I, Chap. 4, § 3; Part VIII, Chap. 1, No. 22.3]. Nevertheless we state the following more general proposition.

Proposition 2. *For every integer $b > 0$ the generating function for the numbers $S_b(n, k)$ of partitions of $[n]$ into k blocks of length at least b is*

$$\sum_{n,k \geqslant 0} S_b(n,k) \frac{x^n}{n!}\, y^k = \exp\left(y \cdot \left(e^x - 1 - x - \frac{x^2}{2!} - \cdots - \frac{x^{b-1}}{(b-1)!} \right) \right).$$

Proof. For $k \geqslant 1$ we have the recurrence relation

$$S_b(n,k) = k\, S_b(n-1,k) + \tbinom{n-1}{b-1}\, S_b(n-b, k-1). \tag{2}$$

In fact, to obtain a partition of $[n]$ into k blocks of lengths at least b, we can either take a partition of $[n-1]$ into k blocks of lengths at least b and append the element n to any one of the k blocks, or we can take $b-1$ elements from $[n-1]$ which together with n constitute a block

with b elements and partition the remaining $n-b$ elements into $k-1$ blocks of lengths at least b.

To prove the proposition we must show that for every integer $k \geqslant 0$

(3)
$$f_k(x) := \sum_{n \geqslant 0} S_b(n,k)\frac{x^n}{n!} = \frac{1}{k!}\Big(e^x - 1 - x - \frac{x^2}{2!} - \cdots - \frac{x^{b-1}}{(b-1)!}\Big)^k.$$

This follows by induction on k. The case $k = 0$ is clear: $S_b(n,0) = \delta_{n,0}$. For $k \geqslant 1$ we get a differential equation for $f_k(x)$, namely

$$\begin{aligned} f_k'(x) &= \sum_n S_b(n,k)\frac{x^{n-1}}{(n-1)!} \\ &\overset{(2)}{=} \sum_n k\, S_b(n-1,k)\frac{x^{n-1}}{(n-1)!} + \sum_n \tbinom{n-1}{b-1} S_b(n-b,k-1)\frac{x^{n-1}}{(n-1)!} \\ &= k\, f_k(x) + \frac{x^{b-1}}{(b-1)!}\, f_{k-1}(x) \\ &= k\, f_k(x) + \frac{x^{b-1}}{(b-1)!}\frac{1}{(k-1)!}\Big(e^x - 1 - x - \frac{x^2}{2!} - \cdots - \frac{x^{b-1}}{(b-1)!}\Big)^{k-1} \end{aligned}$$

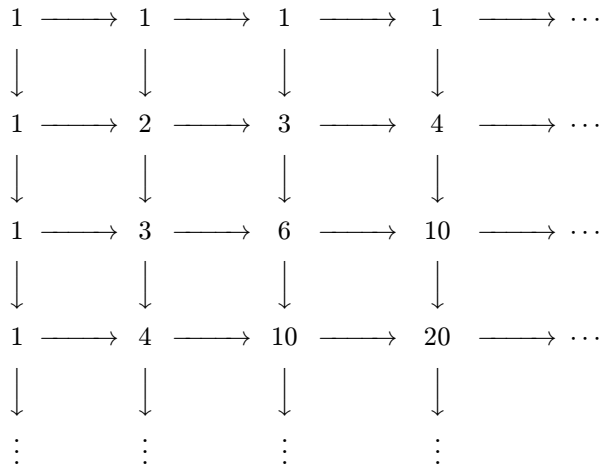
whose unique solution satisfying $f_k(0) = 0$ is in fact given by the right hand side in equation (3). □

The lattices $L(\mathcal{A})$ are graded posets with rank function the codimension. The rth Whitney number of the second kind of a graded poset is by definition the number of elements of rank r. We begin by making the Whitney numbers quite explicit. We fix one of our hyperplane arrangements $\mathcal{A}$ in $\mathbb{R}^n$ and let $W(n,r)$ be the rth Whitney number (of the second kind) of the intersection lattice $L(\mathcal{A})$. The Whitney numbers $W(n,n-k)$ when written in an array can be seen as a generalization of Pascal's triangle. In fact, Pascal's triangle arises for the Boolean lattices of type $(\mathsf{A}_1)^n$.

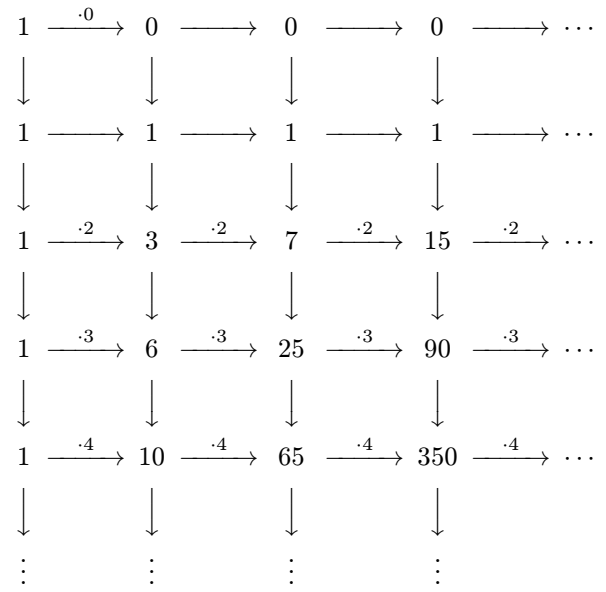
Let us digress for a moment to consider such generalized Pascal triangles or arrays. The (upper left) corner in the arrays that follow carry the Whitney number $W(0,0)$, and the entries (p,q) for the other Whitney numbers $W(p,q)$ are in accordance with the following diagram.

$$\begin{array}{ccc} W(n,n-k) & \longrightarrow & W(n+1,n-k+1) \\ \downarrow & & \\ W(n+1,n-k) & & \end{array}$$

- **Pascal arrangements** = Coxeter arrangements of type $(\mathsf{A}_1)^n$. $W(n, n-k) = \binom{n}{k}$.



- **Stirling arrangements** = Coxeter arrangements of type A_{n-1}. $W(n, n-k) = S(n, k)$. For the A_{n-1} lattices the analogue of the equation $\binom{n}{k} = \binom{n-1}{k} + \binom{n-1}{k-1}$ reads $S(n,k) = k\,S(n-1,k) + S(n-1,k-1)$, the case $b = 1$ of (2).



- **2-Dowling arrangements** = Coxeter arrangements of type B_n. $W(n, n-k) = T(n,k)$. For the B_n lattices the Whitney numbers satisfy the relation $T(n,k) = (2k+1)\,T(n-1,k) + T(n-1,k-1)$ (see Corollary 5).

$$\begin{array}{ccccccccc}

\end{array}$$

Continuing in the obvious way, one gets Whitney numbers of Dowling lattices corresponding to the complete monomial groups $(\mathbb{Z}/m\mathbb{Z}) \wr \mathfrak{S}_n$, the wreath product of the symmetric group of degree n acting on $(\mathbb{Z}/m\mathbb{Z})^n$. This is straightforward, and calculations can be found in [Be1, Be2]. For the D_n lattices the situation is more subtle. The following table suggests why this is so.

type	exponents
$(\mathsf{A}_1)^n$	$1, 1, \ldots, 1$
A_n	$1, 2, \ldots, n$
B_n	$1, 3, \ldots, 2n-1$
D_n	$1, 3, \ldots, 2n-3, n-1$

The maverick exponent $n-1$ for type D_n reveals the fact that the determinant of a $2n \times 2n$ skew-symmetric matrix is the square of a polynomial in the matrix entries.

This ends our digression. Also from now on we will neglect the nearly trivial case of type $(\mathsf{A}_1)^n$.

Proposition 3. *The Whitney numbers $W(n, n-k)$ are given by the following formulae.*

type	$W(n, n-k)$
A_{n-1}	$S(n,k)$
B_n	$\sum_{j=k}^{n} 2^{j-k}\binom{n}{j}\, S(j,k)$
D_n	$\sum_{j=k}^{n} 2^{j-k}\binom{n}{j}\, S(j,k) - 2^{n-1-k} n\, S(n-1,k)$

Proof. The proof follows by elementary combinatorial reasoning from the table in Lemma 1. (Recall that $S(n,k)$ is a Stirling number of the second kind.) □

The table in Proposition 3 can also be found in the last corollary of [Za].

Theorem 4. *The generating functions for the Whitney numbers are as given in the following table.*

type	$\sum_{n,k\geqslant 0} W(n,n-k)\frac{x^n}{n!}\, y^k$
A	$\exp\big(y\cdot(e^x-1)\big)$
B	$e^x \exp\Big(\frac{y}{2}\cdot\big(e^{2x}-1\big)\Big)$
D	$(e^x - x)\exp\Big(\frac{y}{2}\cdot\big(e^{2x}-1\big)\Big)$

Proof. For type A this is Proposition 2 with $b=1$. For type B the coefficients

$$a_n(y) = \sum_{k\geqslant 0}\sum_{j=k}^{n} 2^{j-k}\binom{n}{j}\, S(j,k)\, y^k \in \mathbb{Z}[y]$$

are the binomial transforms of

$$b_j(y) = \sum_{k\geqslant 0} 2^{j-k} S(j,k)\, y^k \in \mathbb{Z}[y].$$

Hence

$$\begin{aligned}\sum_{n\geqslant 0} a_n(y)\frac{x^n}{n!} &= e^x \sum_{j\geqslant 0} b_j(y)\frac{x^j}{j!} \\ &= e^x \sum_{j,k} S(j,k)\frac{(2x)^j}{j!}\Big(\frac{y}{2}\Big)^k = e^x \exp\Big(\frac{y}{2}\cdot\big(e^{2x}-1\big)\Big).\end{aligned}$$

Finally, for type D we need to subtract

$$\sum_{n,k} 2^{n-1-k} n\, S(n-1,k) \frac{x^n}{n!}\, y^k = x \sum_{n,k} S(n-1,k) \frac{(2x)^{n-1}}{(n-1)!} \Big(\frac{y}{2}\Big)^k$$
$$= x \exp\Big(\frac{y}{2} \cdot \big(e^{2x} - 1\big)\Big)$$

from the generating function for type B. □

Setting $y = 1$ in Theorem 4 we get the exponential generating function for the numbers of vertices in the Hasse diagrams. The coefficients in this exponential generating function are the Bell numbers for type A and the Dowling numbers for type B. For type D these numbers are apparently unnamed.

Corollary 5. *The Whitney numbers $T(n,k) = W(n,n-k)$ for the 2-Dowling arrangements satisfy the recurrence relation*

$$T(n,k) = (2k+1)\, T(n-1,k) + T(n-1,k-1).$$

Proof. $\Big(\dfrac{\partial}{\partial x} - 2\, y\, \dfrac{\partial}{\partial y} - 1 - y\Big)\, e^x \exp\Big(\dfrac{y}{2} \cdot \big(e^{2x} - 1\big)\Big) = 0.$ □

Edges in the Hasse diagrams

There are two obvious ways to count edges in a Hasse diagram. Namely, go through all vertices and add up the numbers of edges that go upwards, or, dually, that go downwards. As the result of Orlik and Solomon for the elements of rank 1 suggests, it is easier here to count edges corresponding to vertices that cover a given vertex than to count those edges corresponding to vertices that are covered by a given vertex.

An edge in the Hasse diagram for $L(\mathcal{A})$ emanating in an upward direction from $E \in L(\mathcal{A})$ corresponds to a subspace $E' \in L(\mathcal{A})$ of codimension 1 in E. We shall count how many such subspaces are contained in E.

Schematically, we have

$$\big(\{B_1, \ldots, B_k\}, \zeta\big) \rightsquigarrow \big(\{B'_1, \ldots, B'_{k-1}\}, \zeta'\big)$$

with

$$E = \left\{ (x_1, \ldots, x_n) \in \mathbb{R}^n \;\middle|\; \begin{array}{l} a \in [n] - B \implies x_a = 0 \\ b, c \in B_j \text{ for some } j \implies \zeta(b)\, x_b = \zeta(c)\, x_c \end{array} \right\}$$

where $B = B_1 \cup \cdots \cup B_k$, and E' is obtained by imposing a further equation,

$$E' = \left\{ (x_1, \ldots, x_n) \in \mathbb{R}^n \;\middle|\; \begin{array}{l} a \in [n] - B' \implies x_a = 0 \\ b, c \in B'_j \text{ for some } j \implies \zeta'(b)\, x_b = \zeta'(c)\, x_c \end{array} \right\}$$

where $B' = B'_1 \cup \cdots \cup B'_{k-1}$.

Imposing a further equation may have two different types of incarnations in terms of normal forms. (As usual, $\widehat{B_k}$ means that B_k is omitted.)

- **Fusing two blocks**. Choose $1 \leqslant i < j \leqslant k$, $\varepsilon \in \{\pm 1\}$.

$$\left|\begin{array}{l} \{B'_1, \ldots, B'_{k-1}\} := \{B_1, \ldots, \widehat{B_i}, \ldots, \widehat{B_j}, \ldots, B_k, B_i \cup B_j\} \\ \zeta'(a) := \begin{cases} \zeta(a) & \text{if } a \in B - B_j \\ \varepsilon \cdot \zeta(a) & \text{if } a \in B_j \end{cases} \end{array}\right.$$

- **Dropping one block**. Choose $1 \leqslant i \leqslant k$.

$$\left|\begin{array}{l} \{B'_1, \ldots, B'_{k-1}\} := \{B_1, \ldots, \widehat{B_i}, \ldots, B_k\} \\ \zeta'(a) := \zeta(a) \text{ for all } a \in B - B_i \end{array}\right.$$

Lemma 6. *For*

$$\big(\{B_1, \ldots, B_k\}, \zeta\big) \rightsquigarrow \big(\{B'_1, \ldots, B'_{k-1}\}, \zeta'\big)$$

with fixed $\big(\{B_1, \ldots, B_k\}, \zeta\big)$ *there are the following numbers of possibilities for fusing two blocks or dropping one block.*

type	conditions	fusing	dropping
A_{n-1}	$B = [n]$, $\zeta = 1$ $B' = [n]$, $\zeta' = 1$	$\binom{k}{2}$	0
B_n	—	$\binom{k}{2} \cdot 2$	k
D_n	$\big\lvert[n] - B\big\rvert \neq 1$ $\big\lvert[n] - B'\big\rvert \neq 1$	$\binom{k}{2} \cdot 2$	$\begin{cases} k & \text{if } B \neq [n] \\ \#\big\{i \;\big\vert\; \lvert B_i\rvert \geqslant 2\big\} & \text{if } B = [n] \end{cases}$

The total number of subspaces of dimension $k-1$ in $L(\mathcal{A})$ lying in some fixed subspace $E \in L(\mathcal{A})$ of dimension k is thus $\binom{k}{2}$ for type A and k^2 for type B, while for type D this number is not specified by the dimension alone and can vary between $k^2 - k$ and k^2.

The following diagrams give a rough idea of how the Hasse diagrams look for the first few lattices in the D-series. The first diagram abbreviates the relevant piece of information for the Hasse diagram of the B_3 lattice, whose full form was given earlier. For instance the Hasse diagram for D_4 contains

$$1 \cdot 12 + 12 \cdot 7 + 16 \cdot 3 + 18 \cdot 4 + 24 \cdot 1 + 1 \cdot 0 = 240$$

edges.

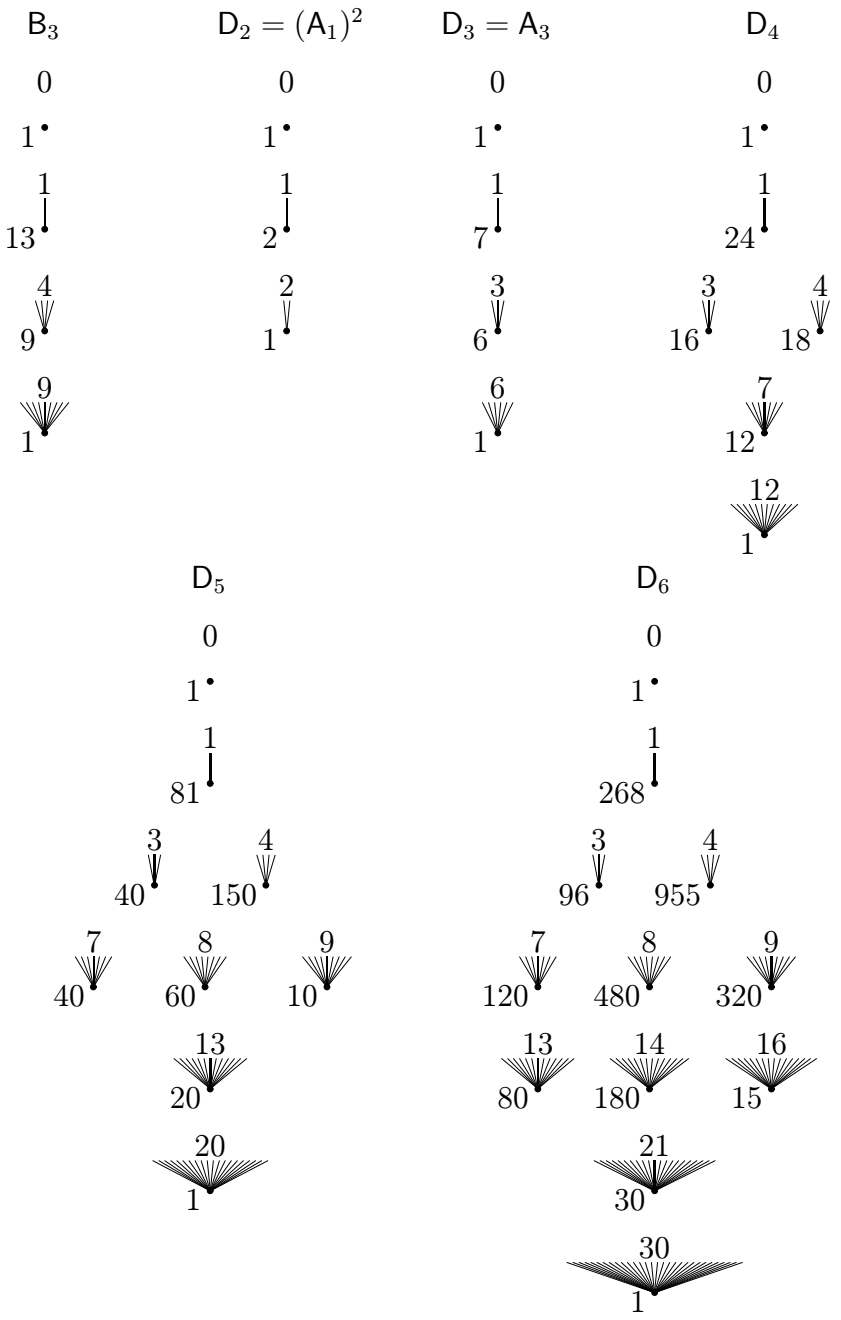

FIGURE 2. Abbreviated Hasse diagrams

Theorem 7. *The exponential generating functions for the numbers of edges in the Hasse diagrams for types* $(\mathsf{A}_{n-1})_{n\geqslant 0}$, $(\mathsf{B}_n)_{n\geqslant 0}$, *and* $(\mathsf{D}_n)_{n\geqslant 0}$

are as given in the following table.

type	exponential generating function
A	$\frac{1}{2}(e^x-1)^2\exp(e^x-1)$
B	$e^x\frac{1}{4}\big(e^{4x}-1\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1\big)\Big)$
D	$(e^x-1-x)\frac{1}{4}\big(e^{4x}-1\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1\big)\Big)$ $+\,e^x\frac{1}{4}\big(e^{4x}-1-4x\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1-2x\big)\Big)$

Proof. For type A_{n-1} there are $S(n,k)$ k-dimensional subspaces each containing $\binom{k}{2}$ subspaces in $L(\mathcal{A})$ of codimension 1. Thus we get the generating function

$$\begin{aligned}\sum_{n,k} S(n,k)\tbinom{k}{2}\frac{x^n}{n!} &= \frac{1}{2}\frac{\partial^2}{\partial y^2}\sum_{n,k} S(n,k)\frac{x^n}{n!}\,y^k\Big|_{y=1}\\ &= \frac{1}{2}\frac{\partial^2}{\partial y^2}\exp\big(y\cdot(e^x-1)\big)\Big|_{y=1} = \frac{1}{2}(e^x-1)^2\exp(e^x-1).\end{aligned}$$

For type B_n there are $\sum_{j=k}^{n} 2^{j-k}\binom{n}{j}\,S(j,k)$ k-dimensional subspaces each containing k^2 subspaces in $L(\mathcal{A})$ of codimension 1. Thus we get the generating function

$$\begin{aligned}&\sum_{n,k}\sum_{j=k}^{n} 2^{j-k}\tbinom{n}{j}\,S(j,k)\,k^2\frac{x^n}{n!}\\ &\quad= \sum_{j,n}\frac{x^{n-j}}{(n-j)!}\frac{\partial}{\partial y}\,y\frac{\partial}{\partial y}\sum_{k} 2^{j-k}S(j,k)\frac{x^j}{j!}\,y^k\Big|_{y=1}\\ &\quad= \sum_{m\geqslant 0}\frac{x^m}{m!}\frac{\partial}{\partial y}\,y\frac{\partial}{\partial y}\sum_{j,k} 2^{j-k}S(j,k)\frac{x^j}{j!}\,y^k\Big|_{y=1}\\ &\quad= \sum_{m\geqslant 0}\frac{x^m}{m!}\frac{\partial}{\partial y}\,y\frac{\partial}{\partial y}\exp\Big(\frac{y}{2}\cdot\big(e^{2x}-1\big)\Big)\Big|_{y=1}\\ &\quad= \sum_{m\geqslant 0}\frac{x^m}{m!}\frac{1}{4}\big(e^{4x}-1\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1\big)\Big)\\ &\quad= e^x\frac{1}{4}\big(e^{4x}-1\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1\big)\Big).\end{aligned}$$

The reader may wonder why we did not insert the formula for

$$\sum_{n,k}\sum_{j} 2^{j-k}\tbinom{n}{j}\, S(j,k)\frac{x^n}{n!}\, y^k$$

directly. The reason for going through the seemingly arcane substitution $m = n - j$ is that we can then use this calculation for type D. Namely, for type D we must subtract the terms for $j = n-1$ and $j = n$, that is, for $m = 1$ and $m = 0$ in the generating function for B and then add the modified term corresponding to $j = n$.

Let us direct our attention to the case $B = [n]$ for D_n. We get a partition of $[n]$ into k blocks with exactly h blocks of length 1 by choosing h elements from $[n]$ and partitioning the remaining set of $n - h$ elements into $k - h$ blocks of lengths at least 2. Taking into account also the choice of $\zeta : [n] \to \{\pm 1\}$, we have

$$2^{n-k}\tbinom{n}{h}\, S_2(n-h, k-h)$$

elements of rank $n - k$ in the Hasse diagram for D_n which are covered by $k^2 - h$ elements. The modified term corresponding to $j = n$ is thus

$$\begin{aligned}
&\sum_{n,k}\sum_{h} 2^{n-k}\tbinom{n}{h}\, S_2(n-h,k-h)\,(k^2-h)\frac{x^n}{n!}\\
&\quad= \sum_{n,k}\sum_{h} \frac{x^h}{h!}\, 2^{n-k} S_2(n-h,k-h)\,(k^2-h)\frac{x^{n-h}}{(n-h)!}\, y^k\Big|_{y=1}\\
&\quad= \sum_{h} \frac{x^h}{h!}\Big(\frac{\partial}{\partial y}\, y\frac{\partial}{\partial y} - h\Big) y^h \sum_{n,k} 2^{n-k} S_2(n-h,k-h)\frac{x^{n-h}}{(n-h)!}\, y^{k-h}\Big|_{y=1}\\
&\quad= \sum_{h} \frac{x^h}{h!}\Big(\frac{\partial}{\partial y}\, y\frac{\partial}{\partial y} - h\Big) y^h \exp\Big(\frac{y}{2}\cdot\big(e^{2x}-1-2x\big)\Big)\Big|_{y=1}\\
&\quad= \sum_{h} \frac{x^h}{h!}\Big(h^2 - h + (2h+1)\frac{1}{2}\big(e^{2x}-1-2x\big) + \frac{1}{4}\big(e^{2x}-1-2x\big)^2\Big)\\
&\qquad\qquad\qquad\qquad\qquad\qquad \times \exp\Big(\frac{1}{2}\big(e^{2x}-1-2x\big)\Big)\\
&\quad= e^x\Big(x^2 + (2x+1)\frac{1}{2}\big(e^{2x}-1-2x\big) + \frac{1}{4}\big(e^{2x}-1-2x\big)^2\Big)\\
&\qquad\qquad\qquad\qquad\qquad\qquad \times \exp\Big(\frac{1}{2}\big(e^{2x}-1-2x\big)\Big)\\
&\quad= e^x\frac{1}{4}\big(e^{4x}-1-4x\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1-2x\big)\Big).
\end{aligned}$$

The exponential generating function for the numbers of edges for the D-series therefore takes the form

$$(e^x-1-x)\frac{1}{4}\big(e^{4x}-1\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1\big)\Big)+e^x\frac{1}{4}\big(e^{4x}-1-4x\big)\exp\Big(\frac{1}{2}\big(e^{2x}-1-2x\big)\Big).$$

□

A curious determinant

Apparently it was A. Lenard who discovered that the Hankel determinant with the Bell numbers as entries is a superfactorial (see the reference in [We]). Let us compute its B-analogue. So let the Dowling numbers D_n be given by

$$\sum_{n\geqslant 0} D_n\frac{x^n}{n!} = e^x\exp\Big(\frac{1}{2}\big(e^{2x}-1\big)\Big).$$

Proposition 8.

$$\begin{vmatrix} D_0 & D_1 & \dots & D_n \\ D_1 & D_2 & \dots & D_{n+1} \\ \vdots & \vdots & & \vdots \\ D_n & D_{n+1} & \dots & D_{2n} \end{vmatrix} = 2^{n(n+1)/2}\prod_{k=1}^{n} k!$$

We shall prove the following generalization which involves the numbers G_n (for $l=0$) that occurred in Kerber's note [Ke, (7)] in connexion with multiply transitive groups and also in M. Bernstein's and Sloane's "eigen-sequence paper" [BeSl, Table 1(a)] in a new setting.

Proposition 9. *Define the sequence of generalized Bell numbers $(G_n)_{n\geqslant 0}$ depending on l and m by*

$$\sum_{n\geqslant 0} G_n\frac{x^n}{n!} = e^{lx}\exp\Big(\frac{1}{m}\big(e^{mx}-1\big)\Big). \tag{4}$$

Then

$$\begin{vmatrix} G_0 & G_1 & \dots & G_n \\ G_1 & G_2 & \dots & G_{n+1} \\ \vdots & \vdots & & \vdots \\ G_n & G_{n+1} & \dots & G_{2n} \end{vmatrix} = m^{n(n+1)/2}\prod_{k=1}^{n} k! \tag{5}$$

Proof. The statement in [Ko, p. 113/114] can be rephrased by saying that a Hankel determinant does not change its value when the matrix entries are subject to a binomial transform. Hence the determinant in (5) is independent of $l \in \mathbb{Z}$ and consequently also independent of l when l is considered as an indeterminate. Therefore we will assume that $l = 0$ in the definition (4) of the numbers G_n.

As an aside let us mention that the invariance under binomial transform gives the following identity between Hankel determinants with Bell numbers as entries.

$$\begin{vmatrix} B_0 & B_1 & \dots & B_n \\ B_1 & B_2 & \dots & B_{n+1} \\ \vdots & \vdots & & \vdots \\ B_n & B_{n+1} & \dots & B_{2n} \end{vmatrix} = \begin{vmatrix} B_1 & B_2 & \dots & B_{n+1} \\ B_2 & B_3 & \dots & B_{n+2} \\ \vdots & \vdots & & \vdots \\ B_{n+1} & B_{n+2} & \dots & B_{2n+1} \end{vmatrix}$$

To compute the determinant (5) we proceed by induction. Let us first define $H_{n,k} \in \mathbb{Q}[m]$ by

$$\sum_{n \geqslant 0} H_{n,k} \frac{y^n}{n!} = \frac{1}{k!}\, e^{-y} \frac{1}{m^k} \left(\log(1+my)\right)^k \qquad (k = 0, 1, 2, \dots). \tag{6}$$

Note that $H_{n,n} = 1$. Hence with

$$I_{h,n} = \sum_{k=0}^{n} G_{h+k}\, H_{n,k} \tag{7}$$

we have

$$\begin{vmatrix} G_0 & G_1 & \dots & G_n \\ G_1 & G_2 & \dots & G_{n+1} \\ \vdots & \vdots & & \vdots \\ G_n & G_{n+1} & \dots & G_{2n} \end{vmatrix} = \begin{vmatrix} G_0 & \dots & G_{n-1} & I_{0,n} \\ \vdots & & \vdots & \vdots \\ G_{n-1} & \dots & G_{2n-2} & I_{n-1,n} \\ G_n & \dots & G_{2n-1} & I_{n,n} \end{vmatrix}. \tag{8}$$

From

$$\sum_{h,n} I_{h,n} \frac{x^h}{h!} \frac{y^n}{n!} = \exp\Big(\frac{1}{m}\big(e^{mx} - 1\big)\Big) \exp\Big(y \cdot \big(e^{mx} - 1\big)\Big) \tag{9}$$

we see that $I_{0,n} = \dots = I_{n-1,n} = 0$ and $I_{n,n} = m^n \cdot n!$. Hence (5) follows from (8) by induction.

We must finally prove (9). So let us compute:

$$\sum_{h,n} I_{h,n} \frac{x^h}{h!} \frac{y^n}{n!} \overset{(7)}{=} \sum_{h,k,n} G_{h+k}\, H_{n,k} \frac{x^h}{h!} \frac{y^n}{n!}$$

$$\begin{aligned}
&\overset{(6)}{=} \sum_{h,k} G_{h+k} \frac{x^h}{h!} \frac{1}{k!} e^{-y} \frac{1}{m^k} \big(\log(1+my)\big)^k \\
&= e^{-y} \sum_{h,k} G_{h+k} \frac{1}{(h+k)!} \binom{h+k}{h} x^h \frac{1}{m^k} \big(\log(1+my)\big)^k \\
&= e^{-y} \sum_{n} G_n \frac{1}{n!} \Big(x + \frac{1}{m} \log(1+my)\Big)^n \\
&\overset{(4)}{=} e^{-y} \exp\left(\frac{1}{m}\left(e^{m\left(x+\frac{1}{m}\log(1+my)\right)} - 1\right)\right) \\
&= \exp\Big(\frac{1}{m}\big(e^{mx}-1\big)\Big) \exp\Big(y \cdot \big(e^{mx}-1\big)\Big).
\end{aligned}$$

We have thus verified equation (9). □

Acknowledgements. Without Sloane's integer sequence database I would probably never have come across the reference [Ri]. Also at one instance the `gfun` Maple package by Salvy and Zimmermann [SZ] was helpful.

Generating Functions via Hankel and Stieltjes Matrices

Paul Peart and Wen-Jin Woan
Department of Mathematics
Howard University
Washington D.C. 20059
Email address: pp@scs.howard.edu

Abstract: When the Hankel matrix formed from the sequence 1, a_1, a_2, ... has an LDL^T decomposition, we provide a constructive proof that the Stieltjes matrix S_L associated with L is tridiagonal. In the important case when L is a Riordan matrix using ordinary or exponential generating functions, we determine the specific form that S_L must have, and we demonstrate, constructively, a one-to-one correspondence between the generating function for the sequence and S_L. If L is Riordan when using ordinary generating functions, we show how to derive a recurrence relation for the sequence.

Generating Functions via Hankel and Stieltjes Matrices

Abstract

When the Hankel matrix formed from the sequence $1, a_1, a_2, \ldots$ *has an* LDL^T *decomposition, we provide a constructive proof that the Stieltjes matrix* S_L *associated with* L *is tridiagonal. In the important case when* L *is a Riordan matrix using ordinary or exponential generating functions, we determine the specific form that* S_L *must have, and we demonstrate, constructively, a one-to-one correspondence between the generating function for the sequence and* S_L*. If* L *is Riordan when using ordinary generating functions, we show how to derive a recurrence relation for the sequence.*

Keywords. Hankel matrix, Stieltjes matrix, ordinary generating function, exponential generating function, Riordan matrix, LDU decomposition, tridiagonal matrix.

1. Introduction

For each sequence in a large class of important combinatorial sequences, we can derive a closed form expression for an ordinary or exponential generating function starting with the associated Hankel matrix or Stieltjes matrix. In this paper we give explicit relationships between the generating function, the Hankel matrix and the Stieltjes matrix. We also provide several illustrative examples. In [3], some work was done using the Hankel matrix approach, but the conditions under which the method would work were not determined, or were only implicitly conjectured. In the present paper we use the Stieltjes matrix to obtain significant improvements in the analysis and application of the method.

Our basic assumption is that the Hankel matrix generated by the sequence has an LDU factorization, where L is a lower triangular matrix with all diagonal elements equal to one, $U = L^T$, and D is a diagonal matrix with all diagonal elements nonzero. The Hankel matrix generated by the sequence $a_0, a_1, a_2, ...$, is given by the infinite matrix

$$H = \begin{bmatrix} a_0 & a_1 & a_2 & a_3 & a_4 & . \\ a_1 & a_2 & a_3 & a_4 & a_5 & . \\ a_2 & a_3 & a_4 & a_5 & a_6 & . \\ a_3 & a_4 & a_5 & a_6 & a_7 & . \\ a_4 & a_5 & a_6 & a_7 & a_8 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

Without loss of generality we take $a_0 = 1$. A necessary and sufficient condition for H to have an LDU factorization is that H be positive definite. When L is a Riordan matrix (see Section 2) using ordinary or exponential generating functions, our method will find a closed form expression for the generating function of the sequence $1, a_1, a_2, a_3, ...$ In the the ordinary generating function case we can then use [4] to find a recurrence relation for the sequence.

Example 1. Delannoy numbers: $1, 3, 13, 63, 321, 1683, ...$
This is sequence A1850 in [5]. See also [1, p. 81]. We apply Gaussian elimination to the Hankel matrix to obtain

$$H = \begin{bmatrix} 1 & 3 & 13 & 63 & 321 & . \\ 3 & 13 & 63 & 321 & 1683 & . \\ 13 & 63 & 321 & 1683 & 8989 & . \\ 63 & 321 & 1683 & 8989 & 48639 & . \\ 321 & 1683 & 8989 & 48639 & 265729 & . \\ . & . & . & . & . & . \end{bmatrix} =$$

$$\begin{bmatrix} 1 & & & & & . \\ 3 & 1 & & & & . \\ 13 & 6 & 1 & & & . \\ 63 & 33 & 9 & 1 & & . \\ 321 & 180 & 62 & 12 & 1 & . \\ . & . & . & . & . & . \end{bmatrix} \begin{bmatrix} 1 & & & & & . \\ & 4 & & & & . \\ & & 8 & & & . \\ & & & 16 & & . \\ & & & & 32 & . \\ . & . & . & . & . & . \end{bmatrix} \begin{bmatrix} 1 & 3 & 13 & 63 & 321 & . \\ & 1 & 6 & 33 & 180 & . \\ & & 1 & 9 & 62 & . \\ & & & 1 & 12 & . \\ & & & & 1 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

The Stieltjes matrix S_L associated with L is the matrix $S_L = L^{-1}\overline{L}$, where $\overline{L}$ is obtained from L by deleting the first row. (See Section 2 for more details about the Stieltjes matrix.) In Example 1,

$$S_L = \begin{bmatrix} 3 & 1 & & & & . \\ 4 & 3 & 1 & & & . \\ & 2 & 3 & 1 & & . \\ & & 2 & 3 & 1 & . \\ & & & 2 & 3 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

From its definition S_L gives the rule of formation of L. Specifically, it gives a rule for obtaining the n^{th} row of L from the previous row. In the example, we have for $n \geq 1$

$$l_{n0} = 3l_{n-1,0} + 4l_{n-1,1}$$

$$l_{nk} = l_{n-1,k-1} + 3l_{n-1,k} + 2l_{n-1,k+1} \quad , \quad k \geq 1\,.$$

It is convenient to define the leftmost column of L to be the zeroth column, and the first row to be the zeroth row. We say that the zeroth column of L has a $\{3, 4\}$ rule of formation and that the k^{th} column, $k \geq 1$, has a $\{1, 3, 2\}$ rule of formation. Notice that the zeroth column of L contains the Delannoy numbers and that S_L is tridiagonal. In Section 2 we prove that whenever $H = LDU$, then S_L is tridiagonal. From Theorem 2 in Section 2 we see that the Delannoy numbers have a closed-form ordinary generating function given by

$$g(x) = \frac{1}{1 - 3x - 4xf} = \frac{1}{\sqrt{1 - 6x + x^2}}\,,$$

where

$$f(x) = x(1 + 3f + 2f^2) = \frac{1 - 3x - \sqrt{1 - 6x + x^2}}{4x} \ .$$

Since S_L is tridiagonal and L is a Riordan matrix, we can use [4] to obtain for the Delannoy numbers the recurrence

$$\begin{aligned} na_n &= 3(4n-3)a_{n-1} - 19(2n-3)a_{n-2} + 3(4n-9)a_{n-3} - (n-3)a_{n-4}; \\ \text{for } n &\geq 4, \text{ with } a_0 = 1, a_1 = 3, a_2 = 13, a_3 = 63\,. \end{aligned}$$

Example 2. Bell numbers: $1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, ...$
This sequence illustrates the exponential generating function case. It is sequence A110 in [5]. Here

$$L = \begin{bmatrix} 1 & & & & & . \\ 1 & 1 & & & & . \\ 2 & 3 & 1 & & & . \\ 5 & 10 & 6 & 1 & & . \\ 15 & 37 & 31 & 10 & 1 & . \\ . & . & . & . & . & . \end{bmatrix} \text{ and } S_L = \begin{bmatrix} 1 & 1 & & & & . \\ 1 & 2 & 1 & & & . \\ & 2 & 3 & 1 & & . \\ & & 3 & 4 & 1 & . \\ & & & 4 & 5 & . \\ . & . & . & . & . & . \end{bmatrix} .$$

From Theorem 3 in Section 2, the form of S_L indicates that the exponential generating function $g(x)$ of the Bell numbers is given by

$$\ln(g) = \int (1 + f)dx, \quad g(0) = 1,$$

where

$$f'(x) = 1 + f(x), \quad f(0) = 0.$$

So we obtain

$$f(x) = e^x - 1 \quad \text{and} \quad g(x) = e^{e^x - 1}.$$

We have found that the method works for many other important combinatorial sequences. These include

- the Catalan numbers: $1, 1, 2, 5, 14, 42, 132, 429, \ldots$ (sequence A108)
- the shortened Catalan sequence: 1, 2, 5, 14, 42, 132, 429, ...
- the Catalan numbers interspersed with zeros: $1, 0, 1, 0, 2, 0, 5, 0, 14, 0, 42, \ldots$
- central binomial coefficients: $1, 2, 6, 20, 70, 252, , 924, 3432, \ldots$ (A984)

- central trinomial coefficients: $1, 1, 3, 7, 19, 51, 141, \ldots$ (A2426),
- Schröder's numbers: $1, 2, 6, 22, 90, 394, 1806, \ldots$ (A6318)
- Schröder's second problem: $1, 1, 3, 11, 45, 197, 903, 4279, \ldots$ (A1003)
- gamma numbers or Motzkin sums: $1, 0, 1, 1, 3, 6, 15, 36, 91, 232, \ldots$ (A5043)
- Fine numbers: $1, 0, 1, 2, 6, 18, 57, 186, 622, \ldots$ (A957)
- directed animals: $1, 2, 5, 13, 35, 96, 267, 750, 2123, \ldots$ (A5773)
- telephone numbers, or self-inverse permutations: $1, 1, 2, 4, 10, 26, 76, 232, 764, \ldots$ (A85)
- derangement numbers: $1, 0, 1, 2, 9, 44, 265, 1854, 14833, \ldots$ (A166).

In Section 2 we show that whenever $H = LDU$ then S_L is always tridiagonal, and we give the specific form of S_L. Theorem 2 in that section indicates the specific form that S_L must have for L to be a Riordan matrix with ordinary generating functions. Theorem 3 indicates the specific form that S_L must have for L to be Riordan with exponential generating functions. In Section 3 we give some further examples.

2. Definitions and Theorems

Definition. The **Hankel matrix** $H = (h_{nk})_{n,k\geq 0}$ generated by the sequence $1, a_1, a_2, a_3, ...$ is given by

$$h_{00} = 1, \quad h_{nk} = a_{n+k} \quad \text{for} \quad n \geq 0, \quad k \geq 0.$$

Definition. Let $L = (l_{nk})_{n,k\geq 0}$ be a lower triangular matrix with $l_{ii} = 1$ for all $i \geq 0$. The **Stieltjes matrix** S_L associated with L is given by $S_L = L^{-1}\overline{L}$, where $\overline{L}$ is obtained from L by deleting the first row of L. That is, the element in the n^{th} row and k^{th} column of $\overline{L}$ is given by

$$\overline{l}_{nk} = l_{n+1,k}\,.$$

Remark. We note that S_L is unique, and so

$$S_L = S_{\widetilde{L}} \Leftrightarrow L = \widetilde{L}\,.$$

Remark. If $S_L = (s_{ik})_{i,k\geq 0}$ then

$$l_{nk} = \sum_{i\geq o} s_{ik} l_{n-1,i} \quad \text{for} \quad n \geq 1\,.$$

That is, from S_L , we obtain a rule for computing the n^{th} row of L from the $(n-1)^{th}$ row.

Remark. S_L is tridiagonal if and only if there exist sequences $\{\lambda_k\}_{k\geq 0}$, and $\{\mu_k\}_{k\geq 0}$ such that

$$l_{n0} = \lambda_0 l_{n-1,0} + \mu_0 l_{n-1,1} \quad \text{for} \quad n \geq 1,$$

$$l_{nk} = l_{n-1,k-1} + \lambda_k l_{n-1,k} + \mu_k l_{n-1,k+1} \quad \text{for} \quad k \geq 1 \quad \text{and} \quad n \geq 1,$$

and

$$s_{00} = \lambda_0, \quad s_{10} = \mu_0\ , \quad \text{and for} \quad k \geq 1\ ,\ s_{kk} = \lambda_k\ ,\ s_{k+1,k} = \mu_k\,.$$

Definition. A **Riordan matrix with ordinary generating functions** is a lower triangular matrix for which the generating function for the k^{th} column, $k \geq 0$, is given by $g(x)[f(x)]^k$, where

$$g(x) = 1 + g_1 x + g_2 x^2 + \cdots \quad \text{and} \quad f(x) = x + f_2 x^2 + f_3 x^3 + \cdots$$

Definition. A **Riordan matrix with exponential generating functions** is a lower triangular matrix for which the generating function for the k^{th} column, $k \geq 0$, is given by $\frac{1}{k!} g(x)[f(x)]^k$, where

$$g(x) = 1 + g_1 x + g_2 \frac{x^2}{2!} + g_3 \frac{x^3}{3!} + \cdots \quad \text{and} \quad f(x) = x + f_2 \frac{x^2}{2!} + f_3 \frac{x^3}{3!} + \cdots\ .$$

See [2] for a detailed description of Riordan matrices. In [6] Woodson explores other kinds of Riordan matrices.

Theorem 1. *Let $H = (h_{nk})_{n,k\geq 0}$ be the Hankel matrix generated by the sequence $1, a_1, a_2, a_3, ...$ Assume that $H = LDU$ where*

$$L = (l_{nk})_{n,k\geq 0} = \begin{bmatrix} 1 & & & & & . \\ l_{10} & 1 & & & & . \\ l_{20} & l_{21} & 1 & & & . \\ l_{30} & l_{31} & l_{32} & 1 & & . \\ l_{40} & l_{41} & l_{42} & l_{43} & 1 & . \\ . & . & . & . & . & . \end{bmatrix},$$

$$D = \begin{bmatrix} d_0 & & & & & . \\ & d_1 & & & & . \\ & & d_2 & & & . \\ & & & d_3 & & . \\ & & & & d_4 & . \\ . & . & . & . & . & . \end{bmatrix} \qquad d_i \neq 0 \quad for\ all\ i, \qquad U = L^T .$$

That is,

$$h_{nk} = \sum_{i=0}^{k} d_i l_{ki} l_{ni} .$$

Then the Stieltjes matrix S_L is tridiagonal with the form

$$S_L = \begin{bmatrix} \lambda_0 & 1 & & & & . \\ \mu_0 & \lambda_1 & 1 & & & . \\ & \mu_1 & \lambda_2 & 1 & & . \\ & & \mu_2 & \lambda_3 & 1 & . \\ & & & \mu_3 & \lambda_4 & . \\ . & . & . & . & . & . \end{bmatrix},$$

where

$$\lambda_0 = a_1 , \quad \mu_0 = d_1 , \quad \lambda_k = l_{k+1,k} - l_{k,k-1} , \quad \mu_k = \frac{d_{k+1}}{d_k} , \quad k \geq 1 .$$

Proof. We will prove that

$$l_{n0} = a_1 l_{n-1,0} + d_1 l_{n-1,1}$$

and

$$l_{nk} = l_{n-1,k-1} + \lambda_k l_{n-1,k} + \mu_k l_{n-1,k+1} \quad for\ all\ k \geq 1.$$

We use induction on k. From the definition of the Hankel matrix,

$$h_{nk} = h_{n-1,k+1} \quad \text{for all} \quad k \geq 0 \quad \text{and} \quad n \geq 1$$

$$h_{n0} = h_{n-1,1} \Leftrightarrow d_0 l_{n0} = d_0 l_{n-1,0} l_{10} + d_1 l_{n-1,1} l_{11} \Leftrightarrow l_{n0} = a_1 l_{n-1,0} + d_1 l_{n-1,1} \, .$$

$$\begin{aligned} h_{n1} = h_{n-1,2} &\Leftrightarrow d_0 l_{10} l_{n0} + d_1 l_{11} l_{n1} = d_0 l_{20} l_{n-1,0} + d_1 l_{21} l_{n-1,1} + d_2 l_{22} l_{n-1,2} \\ &\Leftrightarrow \quad d_1 l_{n1} = l_{20} l_{n-1,0} - l_{10} l_{n0} + d_1 l_{21} l_{n-1,1} + d_2 l_{n-1,2} \\ &\Leftrightarrow \quad d_1 l_{n1} = d_1 l_{n-1,0} + d_1 (l_{21} - l_{10}) l_{n-1,1} + d_2 l_{n-1,2} \\ &\Leftrightarrow \quad l_{n1} = l_{n-1,0} + \lambda_1 l_{n-1,1} + \mu_1 l_{n-1,2} \end{aligned}$$

Now assume that

$$l_{ni} = l_{n-1,i-1} + \lambda_i l_{n-1,i} + \mu_i l_{n-1,i+1} \quad for \quad 1 \leq i \leq k-1 \, .$$

Then

$$\begin{aligned} h_{nk} \quad = \quad & h_{n-1,k+1} \Leftrightarrow \sum_{i=0}^{k} d_i l_{ki} l_{ni} = \sum_{i=0}^{k+1} d_i l_{k+1,i} l_{n-1,i} \\ \Leftrightarrow \quad & \sum_{i=0}^{k-1} d_i l_{ki} l_{ni} - \sum_{i=0}^{k-1} d_i l_{k+1,i} l_{n-1,i} + d_k l_{nk} = d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\ \Leftrightarrow \quad & d_0 l_{k0} l_{n0} + \sum_{i=1}^{k-1} d_i l_{ki} l_{ni} - \left[d_0 l_{k+1,0} l_{n-1,0} + \sum_{i=1}^{k-1} d_i l_{k+1,i} l_{n-1,i} \right] + d_k l_{nk} \\ = \quad & d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\ \Leftrightarrow \quad & d_0 l_{k0} \left[a_1 l_{n-1,0} + d_1 l_{n-1,1} \right] + \sum_{i=1}^{k-1} d_i l_{ki} l_{ni} \\ & - \left[d_0 (a_1 l_{k0} + d_1 l_{k1}) l_{n-1,0} + \sum_{i=1}^{k-1} d_i l_{k+1,i} l_{n-1,i} \right] + d_k l_{nk} \\ = \quad & d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\ \Leftrightarrow \quad & d_1 l_{k0} l_{n-1,1} + \sum_{i=1}^{k-1} d_i l_{ki} l_{ni} - \left[d_1 l_{k1} l_{n-1,0} + \sum_{i=1}^{k-1} d_i l_{k+1,i} l_{n-1,i} \right] + d_k l_{nk} \\ = \quad & d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\ \Leftrightarrow \quad & d_1 l_{k0} l_{n-1,1} + \sum_{i=1}^{k-1} d_i l_{ki} \left[l_{n-1,i-1} + \lambda_i l_{n-1,i} + \frac{d_{i+1}}{d_i} l_{n-1,i+1} \right] \end{aligned}$$

$$
\begin{aligned}
& - \left[d_1 l_{k1} l_{n-1,0} + \sum_{i=1}^{k-1} d_i l_{n-1,i} \left[l_{k,i-1} + \lambda_i l_{ki} + \frac{d_{i+1}}{d_i} l_{k,i+1} \right] \right] + d_k l_{nk} \\
= \quad & d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\
\Leftrightarrow \quad & d_1 l_{k0} l_{n-1,1} + \sum_{i=1}^{k-1} d_i l_{ki} l_{n-1,i-1} + \sum_{i=1}^{k-1} d_{i+1} l_{ki} l_{n-1,i+1} \\
& - \left[d_1 l_{k1} l_{n-1,0} + \sum_{i=1}^{k-1} d_i l_{k,i-1} l_{n-1,i} + \sum_{i=1}^{k-1} d_{i+1} l_{k,i+1} l_{n-1,i} \right] + d_k l_{nk} \\
= \quad & d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\
\Leftrightarrow \quad & d_1 \left[l_{k0} l_{n-1,1} + l_{k1} l_{n-1,0} - l_{k1} l_{n-1,0} - l_{k0} l_{n-1,1} \right] \\
& + d_2 \left[l_{k2} l_{n-1,1} + l_{k1} l_{n-1,2} - l_{k1} l_{n-1,2} - l_{k2} l_{n-1,1} \right] \\
& + d_3 \left[l_{k3} l_{n-1,2} + l_{k2} l_{n-1,3} - l_{k2} l_{n-1,3} - l_{k3} l_{n-1,2} \right] \\
& ..... \\
& ..... \\
& + d_{k-1} \left[l_{k,k-1} l_{n-1,k-2} + l_{k,k-2} l_{n-1,k-1} - l_{k,k-2} l_{n-1,k-1} - l_{k,k-1} l_{n-1,k-2} \right] \\
& + d_k \left[l_{k,k-1} l_{n-1,k} - l_{kk} l_{n-1,k-1} \right] + d_k l_{nk} \\
= \quad & d_k l_{k+1,k} l_{n-1,k} + d_{k+1} l_{n-1,k+1}
\end{aligned}
$$

$$
\begin{aligned}
\Leftrightarrow \quad & d_k l_{nk} = d_k l_{n-1,k-1} + d_k \left[l_{k+1,k} - l_{k,k-1} \right] l_{n-1,k} + d_{k+1} l_{n-1,k+1} \\
\Leftrightarrow \quad & l_{nk} = l_{n-1,k-1} + \lambda_k l_{n-1,k} + \mu_k l_{n-1,k+1}
\end{aligned}
$$

When S_L has $\lambda_i = \lambda$ and $\mu_i = \mu$ for all $i \geq 1$ we can obtain an ordinary generating function for the sequence $1, a_1, a_2, ...$

Theorem 2. *Let H be the Hankel matrix generated by the sequence $1, a_1, a_2, ...$, and let $H = LDL^T$. Then S_L has the form*

$$
S_L = \begin{bmatrix}
a_1 & 1 & & & & . \\
d_1 & \lambda & 1 & & & . \\
 & \mu & \lambda & 1 & & . \\
 & & \mu & \lambda & 1 & . \\
 & & & \mu & \lambda & . \\
. & . & . & . & . & .
\end{bmatrix},
$$

if and only if the ordinary generating function $g(x)$ *of the sequence* $1, a_1, a_2, ...$ *is given by*

$$g(x) = \frac{1}{1 - a_1 x - d_1 x f}\,,$$

where

$$f = x(1 + \lambda f + \mu f^2)\,, \quad f(0) = 0.$$

Proof. We note that $\mu \neq 0$ and

$$f = \frac{1 - \lambda x - \sqrt{(1-\lambda x)^2 - 4\mu x}}{2\mu x}\,.$$

Consider the lower triangular matrix $\widetilde{L}$ such that the generating function for the k^{th} column is $g(x)[f(x)]^k, \quad k \geq 0$.

$$\begin{aligned} g(x) &= \frac{1}{1 - a_1 x - d_1 x f} \Leftrightarrow g(x) = 1 + a_1 x g(x) + d_1 x g f \\ &\Leftrightarrow \widetilde{l}_{00} = 1 \quad \text{and} \quad [x^n]\, g = a_1\, [x^n]\, xg + d_1\, [x^n]\, xgf \\ &\Leftrightarrow \widetilde{l}_{00} = 1 \quad \text{and} \quad \widetilde{l}_{n0} = a_1 \widetilde{l}_{n-1,0} + d_1 \widetilde{l}_{n-1,1} \quad for \quad n \geq 1. \end{aligned}$$

Also, for $k \geq 1$,

$$\begin{aligned} f &= x(1 + \lambda f + \mu f^2) \Leftrightarrow g f^k = x g f^{k-1} + \lambda x g f^k + \mu x g f^{k+1} \\ &\Leftrightarrow [x^n]\, g f^k = [x^n]\, x g f^{k-1} + \lambda\, [x^n]\, x g f^k + \mu\, [x^n]\, x g f^{k+1} \\ &\Leftrightarrow \widetilde{l}_{nk} = \widetilde{l}_{n-1,k-1} + \lambda \widetilde{l}_{n-1,k} + \mu \widetilde{l}_{n-1,k+1}\,. \end{aligned}$$

Therefore S_L has the given form if and only if $S_L = S_{\widetilde{L}} \Leftrightarrow L = \widetilde{L}$.

We now turn to the exponential generating function case. We get an exponential generating function for the sequence $1, a_1, a_2, ...$ when the sequences $\{\lambda_i\}_{i\geq 0}$ and $\{\frac{\mu_i}{i+1}\}_{i\geq 0}$ are arithmetic sequences.

Theorem 3. *Let* H *be the Hankel matrix generated by the sequence* $1, a_1, a_2, ...$, *and let* $H = LDL^T$. *Then* S_L *has the form given in Theorem 1. If* $\{\lambda_i\}_{i\geq 0}$, *is an arithmetic sequence with common difference* λ *and* $\{\frac{\mu_i}{i+1}\}_{i\geq 0}$ *an arithmetic sequence with common difference* μ *, then the exponential generating function* $g(x)$ *for the sequence* $1, a_1, a_2, ...$ *is given by*

$$\ln(g) = \int (a_1 + d_1 f) dx\,, \qquad g(0) = 1,$$

where f *is given by*

$$f' = 1 + \lambda f + \mu f^2\,, \qquad f(0) = 0\,.$$

Proof. Consider the lower triangular matrix $\widehat{L}$ with $\frac{1}{k!}g(x)[f(x)]^k$ for the exponential generating function of the k^{th} column, $k \geq 0$. We note that $\widehat{L}$ is a Riordan matrix with exponential generating functions.

$$\begin{aligned}\ln(g) &= \int (a_1 + d_1 f)dx \Rightarrow g' = a_1 g + d_1 fg \Rightarrow \left[\frac{x^n}{n!}\right] g' = a_1 \left[\frac{x^n}{n!}\right] g + d_1 \left[\frac{x^n}{n!}\right] fg \\ &\Rightarrow \widehat{l}_{n+1,0} = a_1 \widehat{l}_{n0} + d_1 \widehat{l}_{n1} \Rightarrow \widehat{l}_{n0} = \lambda_0 \widehat{l}_{n-1,0} + \mu_0 \widehat{l}_{n-1,1}\end{aligned}$$

For $k \geq 1$,

$$\begin{aligned}\left(\frac{gf^k}{k!}\right)' &= \frac{g'f^k}{k!} + \frac{gf^{k-1}f'}{(k-1)!} = \frac{a_1 gf^k}{k!} + \frac{d_1 gf^{k+1}}{k!} + \frac{gf^{k-1} + \lambda gf^k + \mu gf^{k+1}}{(k-1)!} \\ &= (a_1 + \lambda k)\frac{gf^k}{k!} + (d_1 + \mu k)\frac{gf^{k+1}}{k!} + \frac{gf^{k-1}}{(k-1)!} \\ &= \frac{gf^{k-1}}{(k-1)!} + \lambda_k \frac{gf^k}{k!} + \frac{\mu_k}{k+1}\frac{gf^{k+1}}{k!}\,.\end{aligned}$$

Therefore

$$\left[\frac{x^n}{n!}\right]\left(\frac{gf^k}{k!}\right)' = \left[\frac{x^n}{n!}\right]\left(\frac{gf^{k-1}}{(k-1)!} + \lambda_k \frac{gf^k}{k!} + \mu_k \frac{gf^{k+1}}{(k+1)!}\right).$$

That is,

$$\begin{aligned}\widehat{l}_{n+1,k} &= \widehat{l}_{n,k-1} + \lambda_k \widehat{l}_{nk} + \mu_k \widehat{l}_{n,k+1}\,, \\ \widehat{l}_{nk} &= \widehat{l}_{n-1,k-1} + \lambda_k \widehat{l}_{n-1,k} + \mu_k \widehat{l}_{n-1,k+1}\,.\end{aligned}$$

Therefore S_L has the given form if and only if $L = \widehat{L}$.

3. Further Examples

Example 3. Derangements: $1, 0, 1, 2, 9, 44, 265, 1854, 14833, ...$
This is sequence A166 in [5]. $H = LDL^T$ and

$$S_L = \begin{bmatrix} 0 & 1 & & & & . \\ 1 & 2 & 1 & & & . \\ & 4 & 4 & 1 & & . \\ & & 9 & 6 & 1 & . \\ & & & 16 & 8 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

This is the exponential case with $\lambda_k = 2k$ and $\mu_k = (k+1)^2$. Therefore $\lambda = 2$ and $\mu = 1$. So $f' = 1 + 2f + f^2$ with $f(0) = 0$. That gives $f = \frac{x}{1-x}$ and $\ln(g) = \int f dx$, $g(0) = 1$. So

$$g(x) = \frac{e^{-x}}{1-x}\,.$$

Example 4. Here we start with a Stieltjes matrix having the form in Theorem 3. The associated sequence is 1,3,10,39,187,1128,8455, ... (sequence A54912 in [5]).

$$S_L = \begin{bmatrix} 3 & 1 & & & & . \\ 1 & 6 & 1 & & & . \\ & 6 & 9 & 1 & & . \\ & & 15 & 12 & 1 & . \\ & & & 28 & 15 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

Here S_L has the form in Theorem 3 with $\lambda = 3$ and $\mu = 2$. Therefore the exponential generating function for the sequence in the leftmost column of L is given by $\ln(g) = \int (3+f)dx, \quad g(0) = 1$ where $f' = 1+3f+2f^2, \quad f(0) = 0$. We get $f = \frac{e^x-1}{2-e^x}$ and

$$g(x) = \sqrt{\frac{e^{5x}}{2-e^x}} = 1+3x+10\frac{x^2}{2!}+39\frac{x^3}{3!}+187\frac{x^4}{4!}+1128\frac{x^5}{5!}+8455\frac{x^6}{6!}+O(x^7)$$

We can also use Theorem 1 to construct L and D. Recall that $d_{i+1} = \mu_i d_i$, and that $d_0 = 1$.

Abstract

We propose and discuss several simple ways of obtaining new enumerative sequences from existing ones. For instance, the number of graphs considered up to the action of an involutory transformation is expressible as the semi-sum of the total number of such graphs and the number of graphs invariant under the involution. Another, less familiar idea concerns even- and odd-edged graphs: the difference between their numbers often proves to be a very simple quantity (such as $n!$). More than 30 new sequences will be constructed by these methods.

1 Introduction

New realities set up new tasks. The *On-line Encyclopedia of Integer Sequences* [18] (in the sequel referred to as the *OEIS*) is a rapidly growing facility, which has been playing a more and more important role in mathematical research. To be a comprehensive reference source, the OEIS needs to include as many naturally defined sequences as possible. The efforts of numerous enthusiasts have been directed towards promoting this aim. The present work has been motivated by the same goals.

A fruitful idea is to generate new sequences from known ones. To implement it, various useful transformations of sequences have been proposed — see [4, 5, 19, 20]. In most cases discussed hitherto, these operations transform one sequence to another.

Here we consider some other operations of a similar type but which are less general, producing new enumerative sequences for graphs from *two* other sequences (in most cases, as their semi-sum). The corresponding relations between the objects being counted are very simple, and, as a rule, already known. However, they have never been analyzed *systematically* (this can be partially explained just by their simplicity: serious researchers rarely considered them as deserving an independent formulation). As we will see, our operations do result in new and interesting sequences. In a sense, they might be considered as already implicitly present in the OEIS. However, they cannot be extracted by a formal rule and thus need to be presented in the OEIS *explicitly*. At the same time, we should avoid trivial sequences — not all new sequences deserve to be added to the OEIS. We will return to this question in Section 5.

1.1 Definitions, classes of graphs

In what follows, n denotes the *order* of a graph, i.e. the number of nodes (or vertices). For uniformity, we always start with the case $n = 1$, and usually n takes all natural values. In other words, we deal with sequences (or lists) of the form $[a(1), a(2), a(3), \ldots]$. N denotes the number of edges (in digraphs they are usually called *arcs*) and if there are n nodes and N edges we will sometimes speak of an (n, N) graph.

Φ stands for an arbitrary class of graphs, undirected or directed. Graphs may have loops but not multiple edges (except for planar maps). The most important specific classes to be considered will be denoted by the following capital Greek letters, sometimes equipped with a symbolic subscript:

- Γ (simple) undirected graphs
- Γ_{l} (undirected) graphs with loops, i.e. symmetric reflexive relations
- Γ_{e} even (i.e. eulerian) graphs
- Γ_{m} median graphs, i.e. (n, N)-graphs with $N = \lceil n(n-1)/4 \rceil$ edges
- Γ_{r} regular graphs with unspecified degrees
- Γ_{t} (vertex-) transitive graphs
- Γ_{c} circulant graphs (i.e. Cayley graphs of cyclic groups)

- Δ digraphs
- $\Delta_{\rm l}$ (binary) relations, i.e. digraphs with loops
- $\Delta_{\rm e}$ balanced digraphs (i.e. eulerian digraphs: in-degree = out-degree for any vertex)
- $\Delta_{\rm c}$ circulant digraphs
- Ω oriented graphs, i.e. antisymmetric relations
- Θ tournaments, i.e. complete oriented graphs
- Λ planar maps (order = #(edges)).

1.2 Enumerative functions

Lower case letters will be used for the cardinalities (denoted by #) of subsets of labeled graphs, and the corresponding capital letters will be used for unlabeled graphs of the same kind. The most important specific quantities to be mentioned are the following:

- a, A = #(all graphs) in a class Φ
- c, C = #(connected graphs)
- d, D = #(disconnected graphs)
- b, B = #(doubly connected graphs) (both the graph and its complement are connected)
- s, S = #(strongly connected digraphs, or strong digraphs)
- G = #(unlabeled self-complementary undirected graphs)
- K = #(unlabeled graphs up to complementarity)
- $f_{\rm E}, F_{\rm E}$ = #(graphs with even number of edges (or arcs)) and
- $f_{\rm O}, F_{\rm O}$ = #(graphs with odd number of edges (or arcs)), where $f = a, c, \ldots, F = A, C, \ldots$

We denote the corresponding functions for n-graphs and (n, N)-graphs by $f(\Phi, n)$, $F(\Phi, n)$ and $f(\Phi, n, N)$, $F(\Phi, n, N)$ (or merely $f(n)$, $f(n, N)$, etc. if the class is understood), where f and F refer to labeled and unlabeled graphs respectively The corresponding exponential generating functions (e.g.f.) for labeled graphs and ordinary generating functions (o.g.f.) for unlabeled graphs are denoted by $\mathbf{f}(z)$, $\mathbf{f}(n, x)$, $\mathbf{f}(z, x)$ and $\mathbf{F}(z)$, $\mathbf{F}(n, x)$, $\mathbf{F}(z, x)$), where the formal variable z corresponds to n and x corresponds to N. In particular, in the labeled case,

$$\mathbf{f}(z, x) = \sum_{n \geq 1} \mathbf{f}(n, x) \frac{z^n}{n!} = \sum_n \sum_N f(n, N) x^N \frac{z^n}{n!}$$

(so as not to confuse $\mathbf{f}(n, x)$ with $\mathbf{f}(z, x)|_{z=n}$, the latter expression will not be used here).

We identify any function $f(n)$ with the sequence of its values $[f(1), f(2), f(3), \ldots]$.

Sequences in [18] will be referred to by their A-numbers. (Many of these sequences were added as a result of the present paper.)

2 Subtraction

We begin with the most trivial case: the subtraction method for calculating objects that do not belong to a given subset of a set. In principle, this is an inexhaustible source of new sequences, but we restrict ourselves to several interesting classes, some of which will be used in what follows.

2.1 Disconnection

Consider an arbitrary class of graphs Φ. Using the above notation, we have for disconnected labeled graphs,

$$d(\Phi, n) = a(\Phi, n) - c(\Phi, n) \tag{1}$$

and for disconnected unlabeled graphs,

$$D(\Phi, n) = A(\Phi, n) - C(\Phi, n) \tag{1*}$$

Usually $c(n)$ is expressible in terms of $a(n)$ and $C(n)$ in terms of $A(n)$, and vice versa, in one of several ways depending on the labeling type and the repetition restrictions. See for example the transformations EULERi/EULER/WEIGH for unlabeled graphs and LOG/EXP for labeled ones [4, 20]. Therefore $d(n)$ (and $D(n)$) can usually be expressed solely in terms of $a(n)$ *or* $c(n)$ (resp., in terms of $A(n)$ or $C(n)$). In any case, (1) and (1*) are much easier for calculations if both $a(n)$ and $c(n)$ (resp., $A(n)$ and $C(n)$) have already been calculated.

2.2 Weak and strong digraphs

In the directed case (including the case of relations), connected digraphs are called *weakly* connected in order to distinguish them from *strongly* connected ones. As in Section 2.1 we may consider two further quantities: digraphs that are not strongly connected and (weakly) connected digraphs that are not strongly connected. Only the latter quantity makes sense for tournaments, because all tournaments are weakly connected. Neither notion makes sense for balanced digraphs, in which case weakly connected digraphs are all strongly connected.

This idea is quite fruitful not only for most of the classes of digraphs defined above but also for example for *semi-regular* digraphs: ones with the same out-degree at all vertices[1].

One further notion, which we will use below (4.1.6), is that of a semi-strong digraph. A digraph is called *semi-strong* if all its weakly connected components are strongly connected (in particular, strong digraphs are semi-strong). In the unlabeled case, moreover, one should make a distinction between (at least) two kinds of semi-strong digraphs: with or without repetitions (i.e. isomorphic components). Again, using the ordinary enumerative relationship "connected – disconnected", one can easily count semi-strong digraphs in any class for which the number of strongly connected ones is known.

In practice, these transformations are less productive since strongly connected digraphs (especially unlabeled ones) have been counted only for few types of digraphs (see, in particular, [26, 11, 12]); two of them will be discussed in 4.1.5.

3 Involutory equivalence

Diverse involutory operations on graphs serve as a source of new sequences.

3.1 Complementarity

Several interesting enumerative sequences are related to the notion of complementary graph.

Many classes of graphs contain a uniquely defined *complete graph* (for every order). In particular, complete graphs exist in the families of ordinary undirected graphs Γ, undirected graphs with loops Γ_1, directed graphs Δ and relations Δ_1. This notion allows us to introduce the *complement* of a graph. This is the graph on the same vertices in which the edges are those not in the complete graph.

[1] And for abstract *automata* [7] (Sect. 6.5). Fully defined automata without outputs and initial states are semi-regular digraphs which may be identified with tuples of mappings of the set of states to itself [12].

3.1.1 Double connection

It is clear that the complement of a disconnected graph is connected. This simple assertion allows us to easily count connected graphs (of given type Φ) whose complement is also connected *and* belongs to the same class. We call them *doubly connected*. In the labeled case their number $b(\Phi, n)$ is given by

$$c(\Phi, n) = b(\Phi, n) + d(\Phi, n),$$

whence by (1),

$$b(\Phi, n) = 2c(\Phi, n) - a(\Phi, n). \tag{2}$$

Likewise for unlabeled graphs,

$$B(\Phi, n) = 2C(\Phi, n) - A(\Phi, n). \tag{2*}$$

Now, for labeled simple undirected graphs,
$a(\Gamma, n) = [1, 2, 8, 64, 1024, 32768, 2097152, \dots]$ = A006125 and
$c(\Gamma, n) = [1, 1, 4, 38, 728, 26704, 1866256, \dots]$ = A001187, resulting in
$b(\Gamma, n) = [1, 0, 0, 12, 432, 20640, 1635360, \dots]$ = A054913.
For labeled digraphs,
$a(\Delta, n) = [1, 4, 64, 4096, 1048576, \dots]$ = A053763 and
$c(\Delta, n) = [1, 3, 54, 3834, 1027080, \dots]$ = A003027, resulting in
$b(\Delta, n) = [1, 2, 44, 3572, 1005584, \dots]$ = A054914.
For unlabeled undirected graphs,
$A(\Gamma, n) = [1, 2, 4, 11, 34, 156, 1044, 12346, 274668, \dots]$ = A000088,
$C(\Gamma, n) = [1, 1, 2, 6, 21, 112, 853, 11117, 261080, \dots]$ = A001349, and we obtain
$B(\Gamma, n) = [1, 0, 0, 1, 8, 68, 662, 9888, 247492, \dots]$ = A054915.
For unlabeled undirected regular graphs,
$A(\Gamma_{\mathrm{r}}, n) = [1, 2, 2, 4, 3, 8, 6, 22, 26, 176, \dots]$ = A005176,
$C(\Gamma_{\mathrm{r}}, n) = [1, 1, 1, 2, 2, 5, 4, 17, 22, 167, \dots]$ = A005177 and
$B(\Gamma_{\mathrm{r}}, n) = [1, 0, 0, 0, 1, 2, 2, 12, 18, 158, \dots]$ = A054916.
For vertex-transitive graphs,
$A(\Gamma_{\mathrm{t}}, n) = [2, 2, 4, 3, 8, 4, 14, 9, 22, \dots]$ = A006799,
$C(\Gamma_{\mathrm{t}}, n) = [1, 1, 2, 2, 5, 3, 10, 7, 18, \dots]$ = A006800 and
$B(\Gamma_{\mathrm{t}}, n) = [0, 0, 0, 1, 2, 2, 6, 5, 14, \dots]$ = A054917.
For unlabeled digraphs,
$A(\Delta, n) = [1, 3, 16, 218, 9608, 1540944, \dots]$ = A000273,
$C(\Delta, n) = [1, 2, 13, 199, 9364, 1530843, \dots]$ = A003085 and
$B(\Delta, n) = [1, 1, 10, 180, 9120, 1520742, \dots]$ = A054918.
For unlabeled (reflexive) relations,
$A(\Delta_{\mathrm{l}}, n) = [2, 10, 104, 3044, 291968, \dots]$ = A000595, therefore, by the EULERi transformation [20],
$C(\Delta_{\mathrm{l}}, n) = [2, 7, 86, 2818, 285382, \dots]$ = A054919 and
$B(\Delta_{\mathrm{l}}, n) = [2, 4, 68, 2592, 278796, \dots]$ = A054920.
For unlabeled symmetric relations (undirected graphs with loops),
$A(\Gamma_{\mathrm{l}}, n) = [2, 6, 20, 90, 544, 5096, 79264, \dots]$ = A000666, therefore, by the EULERi transformation,
$C(\Gamma_{\mathrm{l}}, n) = [2, 3, 10, 50, 354, 3883, 67994, \dots]$ = A054921 and
$B(\Gamma_{\mathrm{l}}, n) = [2, 0, 0, 10, 164, 2670, 56724, \dots]$ = A054922.

Undirected graphs with the median number of edges Γ_{m} need a slight modification of the present approach. Nothing unusual arises for orders $n = 4k$ or $4k+1$. However for $n \equiv 2, 3 \pmod 4$, the graph and its complement have *different* numbers of edges, namely $\lceil n(n-1)/4 \rceil$ and $\lceil n(n-1)/4 \rceil - 1$. We will use a prime $'$ in the symbols for the latter case. Now, in order to count doubly connected median graphs, one should, instead of doubling $C(\Gamma_{\mathrm{m}}, n)$ as in (2*), take the sum $C(\Gamma_{\mathrm{m}}, n) + C'(\Gamma_{\mathrm{m}}, n)$. In other words we have

$$B(\Gamma_{\mathrm{m}}, n) = C(\Gamma_{\mathrm{m}}, n) + C'(\Gamma_{\mathrm{m}}, n) - A(\Gamma_{\mathrm{m}}, n). \tag{2'}$$

Indeed, we have $C = B + D'$ and $A' = C' + D'$. By definition, A' counts graphs that are complementary to ones counted by A, i.e. $A = A'$. These equalities give (2').

Numerically, for unlabeled undirected graphs with n nodes and $N = \lceil n(n-1)/4 \rceil$ edges,
$A(\Gamma_m, n) = [1, 1, 1, 3, 6, 24, 148, 1646, 34040, \dots] =$ A000717,
$C(\Gamma_m, n) = [1, 1, 1, 2, 5, 22, 138, 1579, 33366, \dots] =$ A001437
and by the two-parameter table A054924,
$C'(\Gamma_m, n) = [1, 0, 0, 2, 5, 19, 132, 1579, 33366, \dots] =$ A054926, whence
$B(\Gamma_m, n) = [1, 0, 0, 1, 4, 17, 122, 1512, 32692, \dots] =$ A054927.

Of course, such a generalization can be applied to other similar classes of graphs (for example, regular of prescribed degree).

3.1.2 Self-complementarity

Next we consider various classes of graphs that are *invariant* with respect to complementarity. Apart from the classes mentioned in 3.1.1, complementarity is applicable, e.g., to the class of regular graphs of unspecified degrees Γ_r, regular undirected graphs of degree $(n-1)/2$ (n odd), median n-graphs for $n(n-1)$ divisible by 4, undirected eulerian graphs Γ_e of *odd* order, balanced digraphs Δ_e, arbitrary tournaments Θ and regular tournaments Θ_r. On the other hand, e.g., the following classes are not invariant with respect to complementarity: undirected eulerian graphs of even order, graphs with one cycle, graphs without 1-valent nodes, regular undirected graphs of a given degree (not equal to $(n-1)/2$), oriented graphs (except for tournaments), functional digraphs, acyclic digraphs and so on.

For a class of unlabeled graphs Φ counted by $A(\Phi, n)$, let $G(\Phi, n)$ count *self-complementary* graphs (i.e. graphs isomorphic to their complements). We may ask: what is the number $K(\Phi, n)$ of graphs in Φ considered *up to complementarity*?

The complement of a graph looks even more natural if one deals with the pair consisting of a graph and its complement: this may be interpreted as a complete graph with edges of two colors. In these terms, $K(\Phi, n)$ means the number of edge-2-colored unlabeled complete graphs whose colors are *interchangeable* and both one-colored edge subgraphs belong to Φ. The answer to the last question is now very simple:

$$K(\Phi, n) = \frac{A(\Phi, n) + G(\Phi, n)}{2}. \tag{3}$$

Indeed, every graph appears twice in different pairs (graph, complement) as the first or second component, except for the self-complementary graphs, which appear in only one pair. Each pair presents one graph up to complementarity, so $2K(n) = A(n) + G(n)$ (cf. [6]).

This composition can be applied:
to undirected graphs, where $A(\Gamma, n) =$ A000088 is given above and
$G(\Gamma, n) = [1, 0, 0, 1, 2, 0, 0, 10, 36, \dots] =$ A000171, resulting in the sequence
$K(\Gamma, n) = [1, 1, 2, 6, 18, 78, 522, 6178, 137352, \dots] =$ A007869;
to digraphs, where $A(\Delta, n) =$ A000273 and
$G(\Delta, n) = [1, 1, 4, 10, 136, 720, 44224, \dots] =$ A003086, resulting in
$K(\Delta, n) = [1, 2, 10, 114, 4872, 770832, \dots] =$ A054928;
to tournaments, where
$A(\Theta, n) = [1, 1, 2, 4, 12, 56, 456, 6880, 191536, \dots] =$ A000568 and
$G(\Theta, n) = G(\Omega, n) = [1, 1, 2, 2, 8, 12, 88, 176, 2752, \dots]) =$ A002785, resulting in
$K(\Theta, n) = [1, 1, 2, 3, 10, 34, 272, 3528, 97144, \dots] =$ A059735;
to median n-graphs for $n = 4k$ or $4k+1$ (that is, $n = 1, 4, 5, 8, 9 \dots$), where
$A(\Gamma_m, n) = [1, 3, 6, 1646, 34040, \dots] =$ the corresponding subsequence of A000717 (see 3.1.1) and
$G(\Gamma_m, n) = G(\Gamma, n) = [1, 1, 2, 10, 36, \dots] =$ A000171 without zeros (see above), resulting in
$K(\Gamma_m, n) = [1, 2, 4, 828, 17038, \dots]$, $n \equiv 0, 1 \pmod 4$;
to circulant graphs, where
$A(\Gamma_c, n) = [1, 2, 2, 4, 3, 8, 4, 12, 8, 20, 8, 48, 14, 48, 44, 84, 36, 192, \dots]) =$ A049287 and
$G(\Gamma_c, n) = [1, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 4, 0, \dots] =$ A049289, resulting in
$K(\Gamma_c, n) = [1, 1, 1, 2, 2, 4, 2, 6, 4, 10, 4, 24, 8, 24, 22, 42, 20, 96, \dots] =$ A054929;
and to circulant digraphs, where
$A(\Delta_c, n) = [1, 2, 3, 6, 6, 20, 14, 46, 51, 140, 108, \dots] =$ A049297 and

$G(\Delta_c, n) = [1, 0, 1, 0, 2, 0, 2, 0, 3, 0, 4, \ldots] =$ A049309, resulting in
$K(\Delta_c, n) = [1, 1, 2, 3, 4, 10, 8, 23, 27, 70, 56, \ldots] =$ A054930.

In the last two cases, $G(n)$ differ from the corresponding sequences in OEIS by additional zeros interspersed appropriately in order to cover all orders.

One further class of graphs worth mentioning in this respect is that of bipartite graphs; we refer to [16] for enumerative results concerning the function G for such graphs.

In general, this idea can be productively applied to a class of graphs whenever we know any two out of the three corresponding sequences.

3.1.3 A combination

Somewhat more artificially we can apply the same approach to connected graphs, i.e. we consider the number $L(n)$ of unlabeled connected graphs up to complementarity. Complementarity clearly preserves the subclass of connected graphs whose complement is also connected. Thus formula (3) is applicable, giving rise to $L(n) = (B(n) + G(n))/2$, where $B(n)$ is determined by formula (2∗). Thus

$$L(\Phi, n) = C(\Phi, n) - \frac{A(\Phi, n) - G(\Phi, n)}{2}. \tag{4}$$

So, for unlabeled undirected connected graphs, we obtain
$L(\Gamma, n) = [1, 0, 0, 1, 5, 34, 331, 4949, 123764, \ldots] =$ A054931,
and for digraphs,
$L(\Delta, n) = [1, 1, 7, 95, 4628, 760731, \ldots] =$ A054932.

3.2 Arc reversal

We can apply the same idea to other involutory transformations.

Consider first the reversal of arcs in digraphs. Now

$$K_{\mathrm{R}}(\Phi, n) = \frac{A(\Phi, n) + G_{\mathrm{R}}(\Phi, n)}{2}, \tag{3R}$$

where G_{R} stands for the number of self-converse digraphs and K_{R} for the number of (unlabeled) digraphs considered up to reversing the arcs.

For digraphs, $A(\Delta, n) =$ A000273 (see 3.1.1),
$G_{\mathrm{R}}(\Delta, n) = [1, 3, 10, 70, 708, 15224, \ldots] =$ A002499 and we obtain
$K_{\mathrm{R}}(\Delta, n) = [1, 3, 13, 144, 5158, 778084, \ldots] =$ A054933.
For relations, $A(\Delta_l, n) =$ A000595,
$G_{\mathrm{R}}(\Delta_l, n) = [2, 8, 44, 436, 7176, 222368, \ldots] =$ A002500 and
$K_{\mathrm{R}}(\Delta_l, n) = [2, 9, 74, 1740, 149572, 48575680, \ldots] =$ A029849.
For oriented graphs,
$A(\Omega, n) = [1, 2, 7, 42, 582, 21480, 2142288, \ldots] =$ A001174,
$G_{\mathrm{R}}(\Omega, n) = [1, 2, 5, 18, 102, 848, 12452, \ldots] =$ A005639 and we obtain
$K_{\mathrm{R}}(\Omega, n) = [1, 2, 6, 30, 342, 11164, 1077370, \ldots] =$ A054934.

3.3 Planar maps

Equation (3) has a form which is intrinsic for unlabeled objects possessing an additional involutory transformation. Such transformations occur in particular for geometric and topological objects like planar maps.[2]

[2] We notice incidentally that formula (3) is a particular case (for the group of order 2) of the result known as Burnside's Lemma. Formulae (2) and (2∗) are also particular cases of (3).

3.3.1 Duality and reflection

The idea can be applied to planar maps (or maps on other surfaces) with respect to topological duality. For the number $A(\Phi, n)$ of unrooted (= unlabeled) planar maps with n edges in a class of maps Φ and the corresponding number $G_{\mathrm{D}}(\Phi, n)$ of *self-dual* maps, we have, similarly to (3),

$$K_{\mathrm{D}}(\Phi, n) = \frac{A(\Phi, n) + G_{\mathrm{D}}(\Phi, n)}{2}, \tag{3D}$$

where $K_{\mathrm{D}}(\Phi, n)$ denotes the number of unrooted maps considered *up to duality*.

At present, a formula for $G_{\mathrm{D}}(\Phi, n)$ seems to be known in only one case, namely, for the class $\Phi = \Lambda$ of all planar maps considered on the sphere with a distinguished orientation [13]. In this case,

$$K^{+}_{\mathrm{D}}(\Lambda, n) = \frac{A^{+}(\Lambda, n) + G^{+}_{\mathrm{D}}(\Lambda, n)}{2}, \tag{3D^{+}}$$

where the superscript $^{+}$ means enumeration up to *orientation-preserving* transformations. Now,
$A^{+}(\Lambda, n) = [2, 4, 14, 57, 312, 2071, 15030, 117735, 967850, 8268816, \dots] =$ A006384 and
$G^{+}_{\mathrm{D}}(\Lambda, n) = [0, 2, 0, 9, 0, 69, 0, 567, 0, 5112, \dots] =$ A006849 interspersed with 0s. Hence
$K^{+}_{\mathrm{D}}(\Lambda, n) = [1, 3, 7, 33, 156, 1070, 7515, 59151, 483925, 4136964, \dots] =$ A054935.

Instead of duality, let us consider reflections. We obtain the formula

$$A(\Lambda, n) = \frac{A^{+}(\Lambda, n) + G_{\mathrm{ach}}(\Lambda, n)}{2}, \tag{3a}$$

where $G_{\mathrm{ach}}(\Lambda, n)$ denotes the number of *achiral* maps (i.e. maps isomorphic to their mirror images) considered up to orientation-preserving isomorphisms.

Thus from
$A(\Lambda, n) = [2, 4, 14, 52, 248, 1416, 9172, 66366, 518868, 4301350, \dots] =$ A006385 we have
$G_{\mathrm{ach}}(\Lambda, n) = [2, 4, 14, 47, 184, 761, 3314, 14997, 69886, 333884, \dots] =$ A054936. Here it is perhaps more natural to consider maps of the complementary class, i.e. *chiral* maps, i.e.

$$G_{\mathrm{ch}}(\Lambda, n) = A^{+}(\Lambda, n) - A(\Lambda, n) = A(\Lambda, n) - G_{\mathrm{ach}}(\Lambda, n).$$

Hence
$G_{\mathrm{ch}}(\Lambda, n) = [0, 0, 0, 5, 64, 655, 5858, 51369, 448982, 3967466, \dots] =$ A054937.

It would also be interesting to investigate planar maps with respect to the *central symmetry*.

3.3.2 Circular objects

By circular objects we refer to various classes of geometric figures defined inside a disk, or, more concretely, inside a convex (regular) polygon. Examples are *necklaces* (i.e. strings considered up to rotations), triangulations of a polygon and other types of dissections (that is, non-separable outerplanar maps).

Enumerative results for necklaces are well known and widely represented in the OEIS. In particular, there are many sequences enumerating necklaces that can be turned over; such necklaces are sometimes called *bracelets*. For any type of necklace, the same semi-sum formula connects three corresponding sequences that enumerate, respectively, necklaces, bracelets and strings up to both rotations *and* turning over (i.e. reversal or reflection). So whenever two sequences are known, the third can immediately be obtained. Moreover, just as for maps (see 3.3.1), instead of bracelets it is sometimes useful to switch to their complementary set, i.e. to count necklaces that are not isomorphic to their reversals.

Another natural transformation of necklaces is an interchange between bead colors (or string letters). Again, if this is an involution (such as the transposition of two colors), then three appropriate quantities arise which are connected by the same formula (see [6]). Moreover, one may combine this involution with the reversal and count necklaces up to this combined transformation as well as those invariant with respect to it.

An unusual instance of the semi-sum formula arises for two-color necklaces with $2n$ beads in which opposite beads have different colors. In other words, these are necklaces that are self-dual with respect to a

180° rotation combined with the transposition of the colors. According to [14], the number of such self-dual necklaces is given by the expression

$$Q(n) = \frac{h(n) + 2^{\lfloor (n-1)/2 \rfloor}}{2},$$

where

$$h(n) = \frac{1}{2n} \sum_{k|n,\ k \text{ odd}} \phi(k)\, 2^{n/k}$$

involving the Euler totient function $\phi(n)$. This is the sequence
$Q(n) = Q(\Psi, n) = [1, 1, 2, 2, 4, 5, 9, 12, 23, 34, 63, \ldots] =$ A007147.

At the same time,
$h(n) = h(\Theta, n) = [1, 1, 2, 2, 4, 6, 10, 16, 30, 52, 94, \ldots] =$ A000016 enumerates so-called vortex-free labeled tournaments (see in particular [8], p. 14). It is curious to notice that there is also a sensible shift transformation of $Q(n)$: according to [1],

$$Q(n) - [n^2/12] - 1$$

enumerates a class of polytopal spheres, where square brackets mean the nearest integer. Numerically this is
$[0, 0, 0, 0, 1, 1, 4, 6, 15, 25, 52, \ldots] =$ A059736.

Other specific examples of self-dual necklaces can be found, e.g., in [14, 17]. Instead of discussing them here, we turn to an important but less familiar class Ξ of circular object called chord diagrams. A *chord diagram* is a set of chords between pairwise different nodes lying on an oriented circle. Chords may intersect and their sets are considered up to an isotopy transforming the circle to itself. If no restrictions are imposed, the number of chord diagrams $A^+(\Xi, n)$ with n chords and the number of reversible (achiral) chord diagrams $G_{\text{ach}}(\Xi, n)$ can easily be evaluated (see details in [25, 2]). The corresponding (3a)-type formula has $A(\Xi, n)$ on the left-hand side, where $A(\Xi, n)$ denotes the number of chord diagrams considered up to reflection.

Numerically,
$A^+(\Xi, n) = [1, 2, 5, 18, 105, 902, 9749, 127072, 1915951, \ldots] =$ A007769 and
$G_{\text{ach}}(\Xi, n) = [1, 2, 5, 16, 53, 206, 817, 3620, 16361, \ldots] =$ A018191, therefore
$A(\Xi, n) = [1, 2, 5, 17, 79, 554, 5283, 65346, 966156, \ldots] =$ A054499. So, for the complementary sequence of *chiral* chord diagrams $G_{\text{ch}}(\Xi, n) = A(\Xi, n) - G_{\text{ach}}(\Xi, n)$ we obtain
$G_{\text{ch}}(\Xi, n) = [0, 0, 0, 1, 26, 348, 4466, 61726, 949795, \ldots] =$ A054938.

4 Even- and odd-edged graphs

Consider a specific type of sequence: the numbers $f_{\text{E}}(n)$ and $f_{\text{O}}(n)$ of graphs (of a given class with unspecified numbers of edges) with *even* and *odd* numbers of edges. In some non-trivial cases one can easily express both numbers in terms of the numbers of the corresponding graphs. We use a formal approach based on generating functions. The formulae arising in this way are fairly uniform, but require individual proofs. The general idea (going back to [6]) is to evaluate the difference $f_{\text{E}}(\Phi, n) - f_{\text{O}}(\Phi, n)$ (in other words, this is a weighted enumeration of graphs, where an (n, N)-graph gets the weight $(-1)^N$). It is clearly equal to $\mathbf{f}(\Phi, n, -1)$ and often turns out to be a very simple function.

We also consider analogous sequences $F_{\text{E}}(n)$ and $F_{\text{O}}(n)$ for unlabeled graphs, but here fewer results have been obtained.

4.1 Labeled graphs

4.1.1 Connected graphs

For the class Γ, as we know, the e.g.f. of the number $c(n, N)$ of labeled connected (n, N)-graphs satisfies the equation

$$\mathbf{c}(z, x) = \log(1 + \mathbf{a}(z, x)),$$

where the corresponding o.g.f. for n-graphs for varying N are $\mathbf{a}(n,x) = (1+x)^{n(n-1)/2}$ and $\mathbf{c}(n,x) = \sum_N c(n,N)x^N$ (Γ is dropped everywhere for simplicity). Thus $\mathbf{a}(n,-1) = 0$ for $n > 1$, $\mathbf{a}(1,-1) = 1$ and $\mathbf{a}(z,-1) = z$. Hence $\mathbf{c}(z,-1) = \log(1+z)$ and

$$c_{\mathrm{E}}(n) - c_{\mathrm{O}}(n) = \mathbf{c}(n,-1) = -(-1)^n(n-1)!.$$

This is *Amer. Math. Monthly* problem #6673, and in [22] one can find another proof and a generalization to k-component graphs. We notice also that $(-1)^{n-1}(n-1)!$ is the Möbius function of the lattice of set partitions.

Finally, $c_{\mathrm{E}}(n) + c_{\mathrm{O}}(n) = c(n)$, hence

$$c_{\mathrm{E}}(\Gamma,n) = \frac{c(\Gamma,n) - (-1)^n(n-1)!}{2}$$

and

$$c_{\mathrm{O}}(\Gamma,n) = \frac{c(\Gamma,n) + (-1)^n(n-1)!}{2}.$$

Numerically (with $c(\Gamma,n) = [1, 1, 4, 38, 728, 26704, 1866256\ldots] =$ A001187,
$c_{\mathrm{E}}(\Gamma,n) = [1, 0, 3, 16, 376, 13292, 933488, \ldots] =$ A054939 and
$c_{\mathrm{O}}(\Gamma,n) = [0, 1, 1, 22, 352, 13412, 932768, \ldots] =$ A054940.

4.1.2 Connected digraphs

The same result is valid for (weakly) connected labeled digraphs Δ (see my comment in [22]); in the proof we need only use the generating function $(1+x)^{n(n-1)}$ instead of $(1+x)^{n(n-1)/2}$.

4.1.3 Symmetric relations

For the class of graphs with loops Γ_{l}, the same proof with $(1+x)^{n(n+1)/2}$ instead of $(1+x)^{n(n-1)/2}$ results in $\mathbf{a}(z,-1) = 0$ and $\mathbf{c}(n,-1) = 0$. Hence

$$c_{\mathrm{E}}(\Gamma_{\mathrm{l}},n) = c_{\mathrm{O}}(\Gamma_{\mathrm{l}},n) = c(\Gamma_{\mathrm{l}},n)/2$$

(by complementarity, this is evident for $n \equiv 1, 2 \pmod 4$).

4.1.4 Oriented graphs

For oriented graphs Ω, we work with the polynomials $\mathbf{a}(n,x) = (1+2x)^{n(n-1)/2}$, so that $\mathbf{a}(n,-1) = (-1)^{n(n-1)/2}$. Now $\mathbf{a}(z,-1) = \cos(z) + \sin(z) - 1$ and

$$\mathbf{c}(\Omega,z,-1) = \log(\cos(z) + \sin(z)).$$

Therefore
$c_{\mathrm{E}}(\Omega,n) - c_{\mathrm{O}}(\Omega,n) = [1, -2, 4, -16, 80, -512, 3904, -34816, \ldots]$, which is A000831 (the expansion of $(1+\tan x)/(1-\tan x)$) up to alternating signs.
$c_{\mathrm{E}}(\Omega,n) + c_{\mathrm{O}}(\Omega,n) = c(\Omega,n) = [1, 2, 20, 624, 55248, 13982208, \ldots] =$ A054941. Thus
$c_{\mathrm{E}}(\Omega,n) = [1, 0, 12, 304, 27664, 6990848, \ldots] =$ A054942 and
$c_{\mathrm{O}}(\Omega,n) = [0, 2, 8, 320, 27584, 6991360, \ldots] =$ A054943.

4.1.5 Strongly connected digraphs

Proposition. *For labeled strong digraphs,*

$$s_{\mathrm{E}}(\Delta,n) - s_{\mathrm{O}}(\Delta,n) = (n-1)!\,. \tag{5}$$

Remark. This is the *Amer. Math. Monthly* problem [15] mentioned earlier without proof in [22].

Proof. Let $s(n,N) = s(\Delta,n,N)$. The left-hand difference in (5) is $\mathbf{s}(n,-1)$. According to [11] (cf. also [26]),

$$\mathbf{s}(z,x) = -\log(1 - \mathbf{v}(z,x)),$$

where $\mathbf{v}(z,x) = \sum_{n\geq 1} \mathbf{v}(n,x)z^n/n!$, $\mathbf{v}(n,x) = \mathbf{a}(n,x)\,\mathbf{u}(n,x)$, $\mathbf{a}(n,x) = (1+x)^{n(n-1)/2}$, $\mathbf{a}(z,x) = \sum_{n\geq 1} \mathbf{a}(n,x)z^n/n!$ (hence $a(n,N) = a(\Gamma,n,N)$ is the number of all labeled undirected graphs) and

$$\mathbf{u}(z,x) = \sum_{n\geq 1} \mathbf{u}(n,x)\frac{z^n}{n!} = 1 - \frac{1}{1+\mathbf{a}(z,x)}. \tag{6}$$

As we saw in 4.1.1, $\mathbf{a}(n,-1) = 0$ for $n > 1$. Moreover, $\mathbf{a}(1,-1) = \mathbf{u}(1,-1) = 1$. Therefore $\mathbf{v}(z,-1) = z$, whence $\mathbf{s}(z,-1) = -\log(1-z)$ and $\mathbf{s}(n,-1) = (n-1)!$. ∎

Different proofs can be found in [24].

Corollary.

$$s_{\mathrm{E}}(\Delta,n) = \frac{s(\Delta,n) + (n-1)!}{2}$$

and

$$s_{\mathrm{O}}(\Delta,n) = \frac{s(\Delta,n) - (n-1)!}{2}.$$

Thus, from $s(\Delta,n) = [1, 1, 18, 1606, 565080, \ldots]$ = A003030, we obtain $s_{\mathrm{E}}(\Delta,n) = [1, 1, 10, 806, 282552, \ldots]$ = A054944 and $s_{\mathrm{O}}(\Delta,n) = [0, 0, 8, 800, 282528, \ldots]$ = A054945.

Let

$$v(n) = v(\Delta,n) = 2^{n(n-1)/2}u(n),$$

where the e.g.f. $\mathbf{u}(z) = 1 - 1/(1+\mathbf{a}(z))$ and $\mathbf{a}(z) = \sum_{n\geq 1} 2^{n(n-1)/2}z^n/n!$. It is known that $u(n)$ enumerates strong labeled tournaments (see, e.g., [7], (5.2.4)). So this is the sequence $u(n) = s(\Theta,n) = [1, 0, 2, 24, 544, 22320, 1677488, \ldots]$ = A054946. The factors $2^{n(n-1)/2}$ form the sequence $a(\Gamma,n) = a(\Theta,n) = [1, 2, 8, 64, 1024, 32768, 2097152, \ldots]$ = A006125. Thus $v(n) = [1, 0, 16, 1536, 557056, 731381760, \ldots]$ = A054947.

4.1.6 A digression: semi-strong digraphs

As we pointed out in [11], $v(n) = s^{\mathrm{O}}(\Delta,n) - s^{\mathrm{E}}(\Delta,n)$, where $s^{\mathrm{E}}(\Delta,n)$ and $s^{\mathrm{O}}(\Delta,n)$ are the numbers of semi-strong digraphs (see 2.2) with an even and odd *number of components*. Moreover, $s^{\mathrm{O}}(\Delta,n) + s^{\mathrm{E}}(\Delta,n) = s^{\mathrm{W}}(\Delta,n)$, where $s^{\mathrm{W}}(\Delta,n)$ denotes the number of labeled semi-strong digraphs, which is easily expressed via $s(\Delta,n)$ by the EXP transformation [4, 20]. This provides a way to evaluate $s^{\mathrm{E}}(\Delta,n)$ and $s^{\mathrm{O}}(\Delta,n)$. Specifically, $s^{\mathrm{W}}(\Delta,n) = [1, 2, 22, 1688, 573496, 738218192, \ldots]$ = A054948, $s^{\mathrm{O}}(\Delta,n) = [1, 1, 19, 1612, 565276, 734799976, \ldots]$ = A054949 and $s^{\mathrm{E}}(\Delta,n) = [0, 1, 3, 76, 8220, 3418216, \ldots]$ = A054950.

There is a similar formula for the corresponding odd-even difference for unlabeled semi-strong digraphs with *mutually non-isomorphic components*: $V(n) = S^{\mathrm{O}}(\Delta,n) - S^{\mathrm{E}}(\Delta,n)$. This alternating sum plays a key role in the enumeration of unlabeled strongly connected digraphs [11]: $1 - \sum_n V(n)z^n = \prod_n (1-z^n)^{S(\Delta,n)}$. From these formulae one can extract $S^{\mathrm{E}}(\Delta,n)$ and $S^{\mathrm{O}}(\Delta,n)$. First we need to evaluate $V(n)$. In [11] we gave a direct (though difficult) formula and numerical data for the corresponding two-parametric function $V(n,N)$. But now we may proceed in the opposite direction, using the above expression and known values of $S(\Delta,n)$. Numerically, $S(\Delta,n) = [1, 1, 5, 83, 5048, 1047008, \ldots]$ = A035512, whence we evaluate

$V(n) = [1, 1, 4, 78, 4960, 1041872, \dots] =$ A054951. Now $S^{\mathrm{O}}(\Delta, n) + S^{\mathrm{E}}(\Delta, n) = S^{\mathrm{W}}(\Delta, n)$, the number of semi-strong digraphs with pairwise different components. We have $1 + \sum_n S^{\mathrm{W}}(\Delta, n) z^n = \prod_n (1 + z^n)^{S(\Delta, n)}$ (this series corresponds to the WEIGH transformation [4, 5, 20]). Therefore
$S^{\mathrm{W}}(\Delta, n) = [1, 1, 6, 88, 5136, 1052154, \dots] =$ A054952. Thus
$S^{\mathrm{O}}(\Delta, n) = [1, 1, 5, 83, 5048, 1047013, \dots] =$ A054953 and
$S^{\mathrm{E}}(\Delta, n) = [0, 0, 1, 5, 88, 5141, \dots] =$ A054954.

Evidently, other types of disconnected (di)graphs, labeled or unlabeled, specified by the parity of the number of components are also worth considering.

4.1.7 Eulerian digraphs

The next assertion is new.

Proposition. *For labeled balanced digraphs,*

$$a_{\mathrm{E}}(\Delta_{\mathrm{e}}, n) = \frac{a(\Delta_{\mathrm{e}}, n) + n!}{2} \tag{7_{E}}$$

and

$$a_{\mathrm{O}}(\Delta_{\mathrm{e}}, n) = \frac{a(\Delta_{\mathrm{e}}, n) - n!}{2}. \tag{7_{O}}$$

For labeled Eulerian (i.e. connected balanced) digraphs,

$$c_{\mathrm{E}}(\Delta_{\mathrm{e}}, n) = \frac{c(\Delta_{\mathrm{e}}, n) + (n-1)!}{2} \tag{8_{E}}$$

and

$$c_{\mathrm{O}}(\Delta_{\mathrm{e}}, n) = \frac{c(\Delta_{\mathrm{e}}, n) - (n-1)!}{2}. \tag{8_{O}}$$

Proof. According to Theorem 2 of [10], the o.g.f. $\mathbf{a}(\Delta_{\mathrm{e}}, n, x)$ of balanced digraphs can be expressed by a formula in terms of m-roots of unity, $m \geq n$. Choosing $m = n$, and putting $x := -1$, we have from that formula,

$$\mathbf{a}(\Delta_{\mathrm{e}}, n, -1) = n^{-n} n! \prod_{1 \leq k \neq l \leq n} (1 - w^{k-l}),$$

where w is a primitive n-root of unity. Thus

$$\mathbf{a}(\Delta_{\mathrm{e}}, n, -1) = n^{-n} n! \prod_{r=1}^{n} (1 - w^r)^n.$$

But $\prod_r (1 - w^r) = n$, since this is merely the polynomial $(z^n - 1)/(z - 1)$ evaluated at $z = 1$. Thus,

$$\mathbf{a}(\Delta_{\mathrm{e}}, n, -1) = n!$$

This implies formulae (7_{E}) and (7_{O}).

Now, for connected balanced digraphs, $c_{\mathrm{E}}(\Delta_{\mathrm{e}}, n) - c_{\mathrm{O}}(\Delta_{\mathrm{e}}, n) = \mathbf{c}(\Delta_{\mathrm{e}}, n, -1)$. As usual, $\mathbf{c}(\Delta_{\mathrm{e}}, z, x) = \log(1 + \mathbf{a}(\Delta_{\mathrm{e}}, z, x))$. By the above formulae, $\mathbf{a}(\Delta_{\mathrm{e}}, z, -1) = z/(1 - z)$, thus we have $\log(1 + z/(1 - z)) = \sum_{n \geq 1} z^n/n$ and $\mathbf{c}(\Delta_{\mathrm{e}}, n, -1) = (n-1)!$. ∎

Numerically we obtain the following sequences:
$a(\Delta_{\mathrm{e}}, n) = [1, 2, 10, 152, 7736, 1375952, \dots] =$ A007080 whence by (7_{E}),
$a_{\mathrm{E}}(\Delta_{\mathrm{e}}, n) = [1, 2, 8, 88, 3928, 688336, \dots] =$ A054955, and by (7_{O}),
$a_{\mathrm{O}}(\Delta_{\mathrm{e}}, n) = [0, 0, 2, 64, 3808, 687616, \dots] =$ A054956. Now (by the LOG transformation),
$c(\Delta_{\mathrm{e}}, n) = [1, 1, 6, 118, 7000, 1329496, \dots] =$ A054957 so that
$c_{\mathrm{E}}(\Delta_{\mathrm{e}}, n) = [1, 1, 4, 62, 3512, 664808, \dots] =$ A054958 and
$c_{\mathrm{O}}(\Delta_{\mathrm{e}}, n) = [0, 0, 2, 56, 3488, 664688, \dots] =$ A054959.

4.2 Unlabeled graphs

Here we restrict ourselves to one class of graphs, Γ (but compare also 4.1.6). Consider the difference $A_{\mathrm{E}}(\Gamma,n) - A_{\mathrm{O}}(\Gamma,n)$. This is clearly the value at $x = -1$ of the corresponding o.g.f. $\mathbf{A}(\Gamma,n,x) = \sum_N A(\Gamma,n,N)x^N$. According to the Pólya enumeration theorem (see for example [7], (4.1.8)),

$$\mathbf{A}(\Gamma,n,x) = \mathbf{Z}(\mathrm{S}_n^{(2)}, 1+x, 1+x^2, \ldots),$$

where $\mathbf{Z}(\mathrm{S}_n^{(2)}, z_1, z_2, \ldots)$ denotes the cycle index of the symmetric group S_n in its induced action on the 2-subsets of vertices. Thus

$$A_{\mathrm{E}}(\Gamma,n) - A_{\mathrm{O}}(\Gamma,n) = \mathbf{Z}(\mathrm{S}_n^{(2)}, 0, 2, 0, 2, \ldots). \tag{9}$$

We see that the right-hand side coincides with the formula (6.2.3) in [7] for the number $G(\Gamma,n)$ of self-complementary graphs. Thus [23], $A_{\mathrm{E}}(\Gamma,n) - A_{\mathrm{O}}(\Gamma,n) = G(\Gamma,n)$. But
$A_{\mathrm{E}}(\Gamma,n) + A_{\mathrm{O}}(\Gamma,n) = A(\Gamma,n)$. Therefore

$$A_{\mathrm{E}}(\Gamma,n) = \frac{A(\Gamma,n) + G(\Gamma,n)}{2} \tag{10_{E}}$$

and

$$A_{\mathrm{O}}(\Gamma,n) = \frac{A(\Gamma,n) - G(\Gamma,n)}{2}. \tag{10_{O}}$$

So, comparing formulae (10_{E}) and (3), we obtain the following identity:

$$A_{\mathrm{E}}(\Gamma,n) = K(\Gamma,n).$$

We note also that $A_{\mathrm{E}}(\Gamma,n) = A_{\mathrm{O}}(\Gamma,n) = A(\Gamma,n)/2$ if $n = 4k+2$ or $4k+3$.

From the numerical data for $A(\Gamma,n)$ and $G(\Gamma,n)$ (or, instead, $K(\Gamma,n)$) presented in 3.1.1, one gets $A_{\mathrm{O}}(\Gamma,n) = [0, 1, 2, 5, 16, 78, 522, 6168, 137316, \ldots] =$ A054960.

Similar assertions are valid for arbitrary digraphs and some other classes of graphs.

5 Concluding remark

In principle, there is an easy way to obtain numerous new sequences from known ones. Namely, if $a(n)$ and $b(n)$ count objects of two types, then of course their product $a(n)b(n)$ counts ordered pairs of objects, and their sum $a(n) + b(n)$ counts objects of their disjoint union. As a rule this can hardly be considered as a really fruitful idea: in general, such pairs and the union are unnatural. But sometimes, the term-by-term product (and, still more often, the sum) of two sequences turns out to have a natural interpretation, though possibly unexpected. In this work we encountered various sequences that can be presented as the semi-sum or sum of two other sequences. Only one sequence (namely, $v(n)$ in 4.1.5) was presented as the product of two sequences (one of which is, moreover, primitive). Several more such examples can be found in [9]. As far as I know, no systematic investigations of such meaningful operations has been undertaken so far.

Abstract

Let $A(n)$ denote the number of $n \times n$ alternating sign matrices and J_m the m^{th} Jacobsthal number. It is known that

$$A(n) = \prod_{\ell=0}^{n-1} \frac{(3\ell+1)!}{(n+\ell)!}.$$

The values of $A(n)$ are in general highly composite. The goal of this paper is to prove that $A(n)$ is odd if and only if n is a Jacobsthal number, thus showing that $A(n)$ is odd infinitely often.

2000 *Mathematics Subject Classification*: 05A10, 15A15
Keywords: alternating sign matrices, Jacobsthal numbers

1 Introduction

In this paper we relate two seemingly unrelated areas of mathematics: alternating sign matrices and Jacobsthal numbers. We begin with a brief discussion of alternating sign matrices.

An $n \times n$ alternating sign matrix is an $n \times n$ matrix of 1s, 0s and -1s such that

- the sum of the entries in each row and column is 1, and
- the signs of the nonzero entries in every row and column alternate.

Alternating sign matrices include permutation matrices, in which each row and column contains only one nonzero entry, a 1.

For example, the seven 3×3 alternating sign matrices are

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix},$$

$$\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 1 & -1 & 1 \\ 0 & 1 & 0 \end{pmatrix}.$$

The determination of a closed formula for $A(n)$ was undertaken by a variety of mathematicians over the last 25 years or so. David Bressoud's text [1] chronicles these endeavors and discusses the underlying mathematics in a very readable way. See also the survey article [2] by Bressoud and Propp.

As noted in [1], a formula for $A(n)$ is given by

$$A(n) = \prod_{\ell=0}^{n-1} \frac{(3\ell+1)!}{(n+\ell)!}. \tag{1}$$

It is clear from this that, for most values of n, $A(n)$ will be highly composite. The following table shows the first few values of $A(n)$ (sequence A005130 in [8]). Other sequences related to alternating sign matrices can also be found in [8].

n	$A(n)$	Prime Factorization of $A(n)$
1	1	1
2	2	2
3	7	7
4	42	$2 \cdot 3 \cdot 7$
5	429	$3 \cdot 11 \cdot 13$

Table 1: Values of $A(n)$

Examination of this table and further computer calculations reveals that the first few values of n for which $A(n)$ is odd are

$$1, 3, 5, 11, 21, 43, 85, 171.$$

These appear to be the well–known *Jacobsthal numbers* $\{J_n\}$ (sequence A001045 in [8]). They are defined by the recurrence

$$J_{n+2} = J_{n+1} + 2J_n \ , \tag{2}$$

with initial values $J_0 = 1$ and $J_1 = 1$.

This sequence has a rich history, especially in view of its relationship to the Fibonacci numbers. For examples of recent work involving the Jacobsthal numbers, see [3], [4], [5] and [6].

The goal of this paper is to prove that this is no coincidence: for a positive integer n, $A(n)$ is odd if and only if n is a Jacobsthal number.

2 The Necessary Machinery

To show that $A(J_m)$ is odd for each positive integer m, we will show that the number of factors of 2 in the prime decomposition of $A(J_m)$ is zero. To accomplish this, we develop formulas for the number of factors of 2 in

$$N(n) = \prod_{\ell=0}^{n-1} (3\ell+1)! \qquad \text{and} \qquad D(n) = \prod_{\ell=0}^{n-1} (n+\ell)! \ .$$

Once we prove that the number of factors of 2 is the same for $N(J_m)$ and $D(J_m)$, but not the same for $N(n)$ and $D(n)$ if n is not a Jacobsthal number, we will have our result.

We will make frequent use of the following lemma. For a proof, see for example [7, Theorem 2.29].

Lemma 2.1. *The number of factors of a prime p in $N!$ is equal to*

$$\sum_{k\geq 1} \left\lfloor \frac{N}{p^k} \right\rfloor .$$

It follows that the number of factors of 2 in $N(n)$ is

$$N^{\#}(n) = \sum_{\ell=0}^{n-1} \sum_{k\geq 1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = \sum_{k\geq 1} N_k^{\#}(n)$$

where

$$N_k^{\#}(n) = \sum_{\ell=0}^{n-1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor . \tag{3}$$

Similarly, the number of factors of 2 in $D(n)$ is given by

$$D^{\#}(n) = \sum_{\ell=0}^{n-1} \sum_{k\geq 1} \left\lfloor \frac{n+\ell}{2^k} \right\rfloor = \sum_{k\geq 1} D_k^{\#}(n)$$

where

$$D_k^{\#}(n) = \sum_{\ell=0}^{n-1} \left\lfloor \frac{n+\ell}{2^k} \right\rfloor . \tag{4}$$

For use below we note that the recurrence for the Jacobsthal numbers implies the following explicit formula (cf. [9]).

Theorem 2.2. *The m^{th} Jacobsthal number J_m is given by*

$$J_m = \frac{2^{m+1} + (-1)^m}{3}. \tag{5}$$

3 Formulas for $N_k^{\#}(n)$ and $D_k^{\#}(n)$

Lemma 3.1. *The smallest value of ℓ for which*

$$\left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = m,$$

where m and k are positive integers and $k \geq 2$, is

$$\begin{cases} \frac{m}{3}2^k & \text{if} \quad m \equiv 0 \pmod 3 \\ \frac{m-1}{3}2^k + J_{k-1} & \text{if} \quad m \equiv 1 \pmod 3 \\ \frac{m-2}{3}2^k + J_k & \text{if} \quad m \equiv 2 \pmod 3. \end{cases}$$

Proof. Suppose $m \equiv 0 \pmod 3$ and $\ell = \dfrac{m}{3}2^k$. Then

$$\left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = \left\lfloor \frac{3\left(\frac{m}{3}2^k\right)+1}{2^k} \right\rfloor = \left\lfloor \frac{m2^k}{2^k} + \frac{1}{2^k} \right\rfloor = m,$$

and no smaller value of ℓ yields m since the numerators differ by multiples of three.

If $m \equiv 1 \pmod 3$ and $\ell = \dfrac{m-1}{3}2^k + J_{k-1}$, then

$$\begin{aligned} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor &= \left\lfloor \frac{3\left(\frac{m-1}{3}2^k + J_{k-1}\right)+1}{2^k} \right\rfloor \\ &= \left\lfloor \frac{(m-1)2^k + 3\left(\frac{2^k+(-1)^{k-1}}{3}\right)+1}{2^k} \right\rfloor \\ &= \left\lfloor \frac{(m-1)2^k + 2^k + (-1)^{k-1}+1}{2^k} \right\rfloor \\ &= m, \quad \text{if } k \geq 2, \end{aligned}$$

and no smaller value of ℓ yields m.

If $m \equiv 2 \pmod 3$ and $\ell = \dfrac{m-2}{3}2^k + J_k$, then

$$\begin{aligned} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor &= \left\lfloor \frac{3\left(\frac{m-2}{3}2^k + J_k\right)+1}{2^k} \right\rfloor \\ &= \left\lfloor \frac{(m-2)2^k + 3\left(\frac{2^{k+1}+(-1)^k}{3}\right)+1}{2^k} \right\rfloor \\ &= \left\lfloor \frac{(m-2)2^k + 2^{k+1} + (-1)^k+1}{2^k} \right\rfloor \\ &= m, \end{aligned}$$

and no smaller value of ℓ yields m. □

Lemma 3.2. *For any positive integer k, $J_{k-1} + J_k = 2^k$.*

Proof. Immediate from (5). □

Lemma 3.3. *For any positive integer k,*

$$\sum_{v=0}^{2^k-1} \left\lfloor \frac{3v+1}{2^k} \right\rfloor = 2^k.$$

Proof. The result is immediate if $k = 1$. If $k \geq 2$, then by Lemma 3.1, J_{k-1} is the smallest value of v for which $\left\lfloor \frac{3v+1}{2^k} \right\rfloor = 1$ and J_k is the smallest value of v for which $\left\lfloor \frac{3v+1}{2^k} \right\rfloor = 2$. Thus

$$\begin{aligned}
\sum_{v=0}^{2^k-1} \left\lfloor \frac{3v+1}{2^k} \right\rfloor &= 0 \times J_{k-1} + 1 \times [(J_k - 1) - (J_{k-1} - 1)] + 2 \times [(2^k - 1) - (J_k - 1)] \\
&= J_k - J_{k-1} + 2(2^k - J_k) \\
&= 2^{k+1} - 2^k \quad \text{by Lemma 3.2} \\
&= 2^k \ .
\end{aligned}$$

□

Theorem 3.4. *Let $n = 2^k q + r$, where q is a nonnegative integer and $0 \leq r < 2^k$. Then*

$$N_k^{\#}(n) = \left(\frac{n-r}{2^{k+1}}\right)(3(n-r) - 2^k) + tail(n) \tag{6}$$

where

$$tail(n) = \begin{cases} 3qr & \text{if} \quad 0 \leq r \leq J_{k-1} \\ 3qr + (r - J_{k-1}) & \text{if} \quad J_{k-1} < r \leq J_k \\ (3q+2)r - 2^k & \text{if} \quad J_k < r < 2^k. \end{cases} \tag{7}$$

Proof. To analyze the sum

$$N_k^{\#}(n) = \sum_{\ell=0}^{n-1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor$$

we let $\ell = 2^k u + v$, where $0 \leq v < 2^k$. Then

$$\left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = \left\lfloor \frac{3(2^k u + v) + 1}{2^k} \right\rfloor = \left\lfloor \frac{2^k(3u)}{2^k} + \frac{3v+1}{2^k} \right\rfloor = 3u + \left\lfloor \frac{3v+1}{2^k} \right\rfloor.$$

Thus

$$\begin{aligned}
\sum_{\ell=0}^{2^k q - 1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor &= \sum_{u=0}^{q-1} \sum_{v=0}^{2^k-1} \left(3u + \left\lfloor \frac{3v+1}{2^k} \right\rfloor\right) \\
&= \sum_{u=0}^{q-1} \left((3u)2^k + \sum_{v=0}^{2^k-1} \left\lfloor \frac{3v+1}{2^k} \right\rfloor\right) \\
&= \sum_{u=0}^{q-1} ((3u)2^k + 2^k) \quad \text{by Lemma 3.3} \\
&= 2^k \sum_{u=0}^{q-1} (3u+1) \\
&= 2^k \left(3\left(\frac{(q-1)q}{2}\right) + q\right)
\end{aligned}$$

$$
\begin{aligned}
&= 2^k q \left(3\left(\frac{n-r-2^k}{2^{k+1}}\right)+1\right) \\
&= \left(\frac{q}{2}\right)(3(n-r-2^k)+2^{k+1}) \\
&= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k).
\end{aligned}
$$

If $r = 0$, we have our result. If $r > 0$ and $k = 1$, then $r = 1$ and we have one extra term in our sum, namely,

$$\left\lfloor \frac{3(2q)+1}{2} \right\rfloor = 3q$$

and again we have our result since $r = 1$. If $r > 0$ and $k \geq 2$, then by Lemma 3.1, $2^k q$ is the smallest value of ℓ for which $\left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = 3q$, $2^k q + J_{k-1}$ is the smallest value of ℓ for which

$$\left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = 3q+1,$$

and $2^k q + J_k$ is the smallest value of ℓ for which

$$\left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = 3q+2.$$

Hence

$$\sum_{\ell=2^k q}^{2^k q+r-1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor = \begin{cases} 3qr & \text{if} \quad r \leq J_{k-1} \\ 3qJ_{k-1} + (3q+1)(r-J_{k-1}) & \text{if } J_{k-1} < r \leq J_k \\ 3qJ_{k-1} + (3q+1)(J_k - J_{k-1}) + (3q+2)(r-J_k) & \text{if } J_k < r < 2^k. \end{cases}$$

So, if $n = 2^k q + r$ where $0 \leq r < 2^k$,

$$
\begin{aligned}
N_k^{\#}(n) &= \sum_{\ell=0}^{n-1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor \\
&= \sum_{\ell=0}^{2^k q-1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor + \sum_{\ell=2^k q}^{2^k q+r-1} \left\lfloor \frac{3\ell+1}{2^k} \right\rfloor \\
&= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k) + tail(n),
\end{aligned}
$$

where

$$tail(n) = \begin{cases} 3qr & \text{if} \quad r \leq J_{k-1} \\ 3qJ_{k-1} + (3q+1)(r-J_{k-1}) & \text{if } J_{k-1} < r \leq J_k \\ 3qJ_{k-1} + (3q+1)(J_k - J_{k-1}) + (3q+2)(r-J_k) & \text{if } J_k < r < 2^k. \end{cases}$$

The second expression in $tail(n)$ is clearly equal to $3qr + r - J_{k-1}$. For the third expression, we have

$$
\begin{aligned}
3qJ_{k-1} + (3q+1)(J_k - J_{k-1}) + (3q+2)(r-J_k) &= 3qr + J_k - J_{k-1} + 2r - 2J_k \\
&= (3q+2)r - 2^k \quad \text{by Lemma 3.2.}
\end{aligned}
$$

□

Theorem 3.5. *Let $n = 2^k q + r$ where q is a nonnegative integer and $0 \le r < 2^k$. Then we have*

$$D_k^{\#}(n) = \begin{cases} \left(\dfrac{n-r}{2^{k+1}}\right)(3(n+r) - 2^k) & \text{if} \quad 0 \le r \le 2^{k-1} \\ \left(\dfrac{n-(2^k-r)}{2^{k+1}}\right)(3(n-r) + 2^{k+1}) & \text{if} \quad 2^{k-1} < r < 2^k. \end{cases} \tag{8}$$

Proof. We may write

$$D_k^{\#}(n) = \sum_{\ell=0}^{2n-1} \left\lfloor \frac{\ell}{2^k} \right\rfloor - \sum_{\ell=0}^{n-1} \left\lfloor \frac{\ell}{2^k} \right\rfloor.$$

In both sums,

$$\left\lfloor \frac{\ell}{2^k} \right\rfloor = s\,,$$

if $2^k s \le \ell < 2^k(s+1)$, so if $n = 2^k q + r$, where $0 < r \le 2^k$, we have

$$\begin{aligned} \sum_{\ell=0}^{n-1} \left\lfloor \frac{\ell}{2^k} \right\rfloor &= 2^k[1 + 2 + \cdots + q - 1] + qr \\ &= q\left(\frac{n + r - 2^k}{2}\right). \end{aligned}$$

If $0 < r \le 2^{k-1}$, then $2n - 1 = 2^k(2q) + (2r - 1)$, which means

$$\begin{aligned} \sum_{\ell=0}^{2n-1} \left\lfloor \frac{\ell}{2^k} \right\rfloor &= 2^k[1 + 2 + \cdots + (2q-1)] + (2r - 1 + 1)(2q) \\ &= q(2n + 2r - 2^k). \end{aligned}$$

Hence in this case

$$\begin{aligned} D_k^{\#}(n) &= \sum_{\ell=0}^{n-1} \left\lfloor \frac{n+\ell}{2^k} \right\rfloor \\ &= \sum_{\ell=0}^{2n-1} \left\lfloor \frac{\ell}{2^k} \right\rfloor - \sum_{\ell=0}^{n-1} \left\lfloor \frac{\ell}{2^k} \right\rfloor \\ &= q(2n + 2r - 2^k) - q\left(\frac{n + r - 2^k}{2}\right) \\ &= \left(\frac{n-r}{2^{k+1}}\right)(3(n+r) - 2^k). \end{aligned}$$

If $2^{k-1} < r \le 2^k$, say, $r = 2^{k-1} + s$ where $0 < s \le 2^{k-1}$, then

$$\begin{aligned} 2n - 1 &= 2(2^k q + r) - 1 \\ &= 2^k(2q) + 2(2^{k-1} + s) - 1 \\ &= 2^k(2q+1) + 2s - 1. \end{aligned}$$

Thus

$$\begin{aligned}\sum_{\ell=0}^{2n-1}\left\lfloor\frac{\ell}{2^k}\right\rfloor &= 2^k[1+2+\cdots+2q]+(2s-1+1)(2q+1)\\ &= (2q+1)(n+r-2^k).\end{aligned}$$

So in this case

$$\begin{aligned}D_k^{\#}(n) &= \sum_{\ell=0}^{n-1}\left\lfloor\frac{n+\ell}{2^k}\right\rfloor\\ &= \sum_{\ell=0}^{2n-1}\left\lfloor\frac{\ell}{2^k}\right\rfloor-\sum_{\ell=0}^{n-1}\left\lfloor\frac{\ell}{2^k}\right\rfloor\\ &= (2q+1)(n+r-2^k)-q\left(\frac{n+r-2^k}{2}\right)\\ &= \left(\frac{n+r-2^k}{2^{k+1}}\right)(3(n-r)+2^{k+1}).\end{aligned}$$

The reader will note that in the statement of the theorem we have separated the cases according as $0 \le r \le 2^{k-1}$ and $2^{k-1} < r < 2^k$, whereas in the proof the cases are $0 < r \le 2^{k-1}$ and $2^{k-1} < r \le 2^k$. However, these are equivalent since $\frac{n-0}{2^{k+1}}(3(n+0)-2^k) = \frac{n-(2^k-2^k)}{2^{k+1}}(3(n-2^k)+2^{k+1})$. □

4 $A(J_m)$ is odd

Now that we have closed formulas for $N_k^{\#}(n)$ and $D_k^{\#}(n)$ we can proceed to prove that $A(J_m)$ is odd for all Jacobsthal numbers J_m.

Theorem 4.1. *For all positive integers m, $A(J_m)$ is odd.*

Proof. The proof simply involves substituting J_m into (6) and (8) and showing that $N_k^{\#}(J_m) = D_k^{\#}(J_m)$ for all k. This implies that $N^{\#}(J_m) = D^{\#}(J_m)$, and so the number of factors of 2 in $A(J_m)$ is zero. Our theorem is then proved.

We break the proof into two cases, based on whether the parity of k is equal to the parity of m.

- **Case 1:** The parity of m equals the parity of k. Then

$$\begin{aligned}2^k(J_{m-k}-1)+J_k &= 2^k\left(\frac{2^{m-k+1}+(-1)^{m-k}}{3}-1\right)+\frac{2^{k+1}+(-1)^k}{3}\\ &= \frac{2^{m+1}+2^k-3\cdot 2^k+2^{k+1}+(-1)^k}{3} \quad \text{since } (-1)^{m-k}=1\\ &= \frac{2^{m+1}+(-1)^m}{3} \quad \text{since } (-1)^k=(-1)^m\\ &= J_m\end{aligned}$$

  Thus, in the notation of Theorems 3.4 and 3.5, $q = J_{m-k}-1$ and $r = J_k$. We now calculate $N_k^{\#}(J_m)$ and $D_k^{\#}(J_m)$ using Theorems 3.4 and 3.5.

$$\begin{aligned}
N_k^{\#}(J_m) &= \left(\frac{J_m - J_k}{2^{k+1}}\right)\left(3(J_m - J_k) - 2^k\right) \\
&\quad + 3(J_{m-k} - 1)J_k + (J_k - J_{k-1}) \\
&= \frac{1}{2^{k+1}}\left(\frac{2^{m+1} + (-1)^m}{3} - \frac{2^{k+1} + (-1)^k}{3}\right)\left(3\left(\frac{2^{m+1} + (-1)^m}{3} - \frac{2^{k+1} + (-1)^k}{3}\right) - 2^k\right) \\
&\quad + (3J_{m-k} - 1)J_k - 2^k \quad \text{by Lemma 3.2} \\
&= \frac{1}{3 \cdot 2^{k+1}}\left(2^{m+1} - 2^{k+1}\right)\left(2^{m+1} - 2^{k+1} - 2^k\right) \\
&\quad + \left(3\left(\frac{2^{m-k+1} + (-1)^{m-k}}{3}\right) - 1\right)\left(\frac{2^{k+1} + (-1)^k}{3}\right) - 2^k \quad \text{since } (-1)^m = (-1)^k \\
&= \frac{1}{3}\left(2^{2m-k+1} - 2^{m+2} + 2^{k+1} - 2^m + 2^k\right) \\
&\quad + \frac{1}{3}(2^{m-k+1}(2^{k+1} + (-1)^k) - 3 \cdot 2^k) \quad \text{since } (-1)^{m-k} = 1 \\
&= \frac{1}{3}\left(2^{2m-k+1} - 2^m + (-1)^k 2^{m-k+1}\right)
\end{aligned}$$

after much simplification. Next, we calculate $D_k^{\#}(J_m)$, recalling that $2^{k-1} < r = J_k < 2^k$.

$$\begin{aligned}
D_k^{\#}(J_m) &= \frac{\left(J_m - 2^k + J_k\right)}{2^{k+1}}\left(3(J_m - J_k) + 2^{k+1}\right) \\
&= \frac{1}{2^{k+1}}\left(\frac{2^{m+1} + (-1)^m}{3} + \frac{2^{k+1} + (-1)^k}{3} - 2^k\right)\left(3\left(\frac{2^{m+1} + (-1)^m}{3} - \frac{2^{k+1} + (-1)^k}{3}\right) + 2^{k+1}\right) \\
&= \frac{1}{3 \cdot 2^{k+1}}\left(2^{m+1} + 2^{k+1} + 2(-1)^k - 3 \cdot 2^k\right)\left(2^{m+1} - 2^{k+1} + 2^{k+1}\right) \quad \text{since } (-1)^m = (-1)^k \\
&= \frac{1}{3}\left(2^{2m-k+1} + 2^{m+1} + 2^{m-k+1}(-1)^k - 3 \cdot 2^m\right) \\
&= \frac{1}{3}\left(2^{2m-k+1} - 2^m + (-1)^k 2^{m-k+1}\right)
\end{aligned}$$

after simplification. We see that $N_k^{\#}(J_m) = D_k^{\#}(J_m)$.

- **Case 2:** The parity of m is not equal to the parity of k. Then

$$\begin{aligned}
2^k(J_{m-k}) + J_{k-1} &= 2^k\left(\frac{2^{m-k+1} + (-1)^{m-k}}{3}\right) + \frac{2^k + (-1)^{k-1}}{3} \\
&= \frac{2^{m+1} - 2^k + 2^k + (-1)^{k-1}}{3} \\
&= J_m.
\end{aligned}$$

Thus, in the notation of Theorems 3.4 and 3.5, $q = J_{m-k}$ and $r = J_{k-1}$. We now calculate $N_k^{\#}(J_m)$ and $D_k^{\#}(J_m)$ using Theorems 3.4 and 3.5.

$$\begin{aligned}
N_k^{\#}(J_m) &= \left(\frac{J_m - J_{k-1}}{2^{k+1}}\right)\left(3(J_m - J_{k-1}) - 2^k\right) \\
&\quad + 3J_{m-k}J_{k-1}
\end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{2^{k+1}}\left(\frac{2^{m+1}+(-1)^m}{3}-\frac{2^k+(-1)^{k-1}}{3}\right)\left(3\left(\frac{2^{m+1}+(-1)^m}{3}-\frac{2^k+(-1)^{k-1}}{3}\right)-2^k\right)\\
&\quad +3\left(\frac{2^{m-k+1}+(-1)^{m-k}}{3}\right)\left(\frac{2^k+(-1)^{k-1}}{3}\right)\\
&= \frac{1}{3\cdot 2^{k+1}}\left(2^{m+1}-2^k\right)\left(2^{m+1}-2\cdot 2^k\right)\\
&\quad +\frac{1}{3}((2^{m-k+1}-1)(2^k+(-1)^{k-1})) \text{ since } (-1)^m=(-1)^{k-1} \text{ and } (-1)^{m-k}=-1\\
&= \frac{1}{3}(2^{2m-k+1}-2^{m+1}-2^m+2^k+2^{m+1}-2^k+2^{m-k+1}(-1)^{k-1}+(-1)^k)\\
&= \frac{1}{3}(2^{2m-k+1}-2^m+2^{m-k+1}(-1)^{k-1}+(-1)^k)
\end{aligned}
$$

after much simplification. Again we find that $N_k^{\#}(J_m)=D_k^{\#}(J_m)$.

Now we calculate $D_k^{\#}(J_m)$, recalling that $0<r<2^{k-1}$.

$$
\begin{aligned}
D_k^{\#}(J_m) &= \frac{(J_m-J_{k-1})}{2^{k+1}}(3(J_m+J_{k-1})-2^k)\\
&= \frac{1}{2^{k+1}}\left(\frac{2^{m+1}+(-1)^m}{3}-\frac{2^k+(-1)^{k-1}}{3}\right)\left(3\left(\frac{2^{m+1}+(-1)^m}{3}+\frac{2^k+(-1)^{k-1}}{3}\right)-2^k\right)\\
&= \frac{1}{3\cdot 2^{k+1}}(2^{m+1}-2^k)(2^{m+1}+2(-1)^{k-1}) \text{ since } (-1)^m=(-1)^{k-1}\\
&= \frac{1}{3}(2^{2m-k+1}-2^m+2^{m-k+1}(-1)^{k-1}+(-1)^k)
\end{aligned}
$$

after simplification. Again we find that $N_k^{\#}(J_m)=D_k^{\#}(J_m)$.

This completes the proof that $A(J_m)$ is odd for all Jacobsthal numbers J_m.

□

5 The Converse

We now prove the converse to Theorem 4.1. That is, we will prove that $A(n)$ is even if n is not a Jacobsthal number. As a guide in how to proceed, we include a table of values for $N_k^{\#}(n)$ and $D_k^{\#}(n)$ for small values of n and k. This table suggests that $N_k^{\#}(n)\geq D_k^{\#}(n)$ for all positive integers n and k. It also suggests that for each value of n, there is at least one value of k for which $N_k^{\#}(n)$ is strictly greater than $D_k^{\#}(n)$ except when n is a Jacobsthal number. (The rows that begin with a Jacobsthal number are indicated in bold-face.)

n	$N_1^{\#}(n)$	$D_1^{\#}(n)$	$N_2^{\#}(n)$	$D_2^{\#}(n)$	$N_3^{\#}(n)$	$D_3^{\#}(n)$	$N_4^{\#}(n)$	$D_4^{\#}(n)$	$N_5^{\#}(n)$	$D_5^{\#}(n)$	$N_6^{\#}(n)$	$D_6^{\#}(n)$

Table 2: Values for $N_k^{\#}(n)$ and $D_k^{\#}(n)$

(We note in passing that the values of $N_1^{\#}(n)$ form sequence A001859 in [8].)

In order to prove the first assertion (that $N_k^{\#}(n) \geq D_k^{\#}(n)$), we separate the functions defined by the cases in equations (6) and (8) into individual functions denoted by $N_k^{\#(1)}(n), N_k^{\#(2)}(n), \ldots, D_k^{\#(2)}(n)$. That is,

$$\begin{aligned}
N_k^{\#(1)}(n) &:= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k)+3qr \\
N_k^{\#(2)}(n) &:= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k)+3qr+(r-J_{k-1}) \\
N_k^{\#(3)}(n) &:= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k)+(3q+2)r-2^k \\
D_k^{\#(1)}(n) &:= \left(\frac{n-r}{2^{k+1}}\right)(3(n+r)-2^k) \\
D_k^{\#(2)}(n) &:= \left(\frac{n-(2^k-r)}{2^{k+1}}\right)(3(n-r)+2^{k+1})
\end{aligned}$$

For a given value of n, $N_k^{\#}(n)$ will equal $N_k^{\#(i)}(n)$ for some $i \in \{1,2,3\}$ and $D_k^{\#}(n)$ will be $D_k^{\#(j)}(n)$ for some $j \in \{1,2\}$ depending on the value of r. Note that not all combinations of i and j are possible (for example, there is no value of n such that $i=1$ and $j=2$). In Lemmas 5.1 through 5.4 we show that $N_k^{\#(i)}(n) \geq D_k^{\#(j)}(n)$ for all possible combinations of i and j (that correspond to some integer n) which implies that $N_k^{\#}(n) \geq D_k^{\#}(n)$ for all positive integers n.

Lemma 5.1. *For all integers n and k, $N_k^{\#(1)}(n) = D_k^{\#(1)}(n)$.*

Proof. We first note that, in the notation of Theorem 3.4, $\frac{n-r}{2^{k+1}} = \frac{2^k q}{2^{k+1}} = \frac{q}{2}$. Then

$$N_k^{\#(1)}(n) = \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k)+3qr$$

$$
\begin{aligned}
&= \left(\frac{n-r}{2^{k+1}}\right)\left(3(n-r) - 2^k + 3qr\left(\frac{2}{q}\right)\right) \quad \text{since } \frac{n-r}{2^{k+1}} = \frac{q}{2} \\
&= \left(\frac{n-r}{2^{k+1}}\right)(3n + 3r - 2^k) \\
&= D_k^{\#(1)}(n).
\end{aligned}
$$

□

Lemma 5.2. *For all integers k and all integers n such that $r > J_{k-1}$ (in the notation of Theorem 3.4),*

$$N_k^{\#(2)}(n) > D_k^{\#(1)}(n).$$

Proof.

$$
\begin{aligned}
N_k^{\#(2)}(n) &= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r) - 2^k) + 3qr + (r - J_{k-1}) \\
&> \left(\frac{n-r}{2^{k+1}}\right)(3(n-r) - 2^k) + 3qr \quad \text{since } r > J_{k-1} \\
&= N_k^{\#(1)}(n) \\
&= D_k^{\#(1)}(n) \quad \text{by Lemma 5.1.}
\end{aligned}
$$

This proves our result. □

Lemma 5.3. *For all integers k and all integers n such that $r \leq J_k$ (in the notation of Theorem 3.4),*

$$N_k^{\#(2)}(n) \geq D_k^{\#(2)}(n).$$

Proof. We see that $r \leq J_k = 2^k - J_{k-1}$ by Lemma 3.2. Thus, $2^k q + r \leq 2^k(q+1) - J_{k-1}$. This implies $n \leq 2^k(q+1) - J_{k-1}$, so $2n - 2^k(q+1) \leq n - J_{k-1}$. Hence,

$$
\begin{aligned}
N_k^{\#(2)}(n) &= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r) - 2^k) + 3qr + (r - J_{k-1}) \\
&= \frac{q}{2}(3(2^k q) - 2^k) + 3q(n - 2^k q) + n - 2^k q - J_{k-1} \\
&= q^2(-3(2^{k-1})) + q(-3(2^{k-1}) + 3n) + n - J_{k-1} \\
&\geq q^2(-3(2^{k-1})) + q(-3(2^{k-1}) + 3n) + 2n - 2^k(q+1) \quad \text{by the above argument} \\
&= \frac{2n - 2^k - 2^k q}{2^{k+1}}(3(2^k q) + 2^{k+1}) \\
&= D_k^{\#(2)}(n).
\end{aligned}
$$

□

Lemma 5.4. *For all positive integers n and k, $N_k^{\#(3)}(n) = D_k^{\#(2)}(n)$.*

Proof.

$$\begin{aligned} N_k^{\#(3)}(n) &= \left(\frac{n-r}{2^{k+1}}\right)(3(n-r)-2^k)+(3q+2)r-2^k \\ &= \left(\frac{q}{2}\right)(3(2^kq)-2^k)+3q(n-2^kq)+2(n-2^kq)-2^k \\ &= \frac{n-2^k+n-2^kq}{2^k+1}(3(2^kq)+2^{k+1}) \\ &= D_k^{\#(2)}(n). \end{aligned}$$

□

Remark 5.5. *To summarize, Lemmas 5.1 through 5.4 tell us that for any positive integer n,*

$$N_k^{\#}(n) \geq D_k^{\#}(n).$$

For Propositions 5.6 through 5.9 we make the assumption that $J_\ell < n < J_{\ell+1}$ for some positive integer ℓ.

Proposition 5.6. *For ℓ and n, as given above, $N_{\ell+1}^{\#}(n) = n - J_\ell$.*

Proof. By Lemma 3.1,

$$\begin{aligned} \sum_{i=0}^{n-1}\left\lfloor\frac{3i+1}{2^{\ell+1}}\right\rfloor &= 0\times(J_\ell)+1\times((n-1)-(J_\ell-1)) \\ &= n-J_\ell. \end{aligned}$$

□

Proposition 5.7. *$D_k^{\#}(n) = 0$ if $n < 2^{k-1}$. In particular, $D_{\ell+1}^{\#}(n) = 0$ if $n < 2^\ell$.*

Proof. If $n < 2^k$ then, in the notation of Theorem 3.5, $n = r$ and $q = 0$, so by Theorem 3.5, $D_k^{\#}(n) = 0$. □

Proposition 5.8. *$D_{\ell+1}^{\#}(n) = 2(n-2^\ell)$ if $2^\ell \leq n < J_{\ell+1}$.*

Proof. If $2^\ell \leq n < J_{\ell+1}$ then, in the notation of Theorem 3.5, $q = 0$ and $r = n$. Since $n \geq 2^\ell$, we are in the second case of Theorem 3.5 so

$$D_{\ell+1}^{\#}(n) = \frac{n-2^{\ell+1}+n}{2^{\ell+2}}(0+2^{\ell+2}) = 2(n-2^\ell).$$

□

Proposition 5.9. *For n and ℓ as given above, $2(n-2^\ell) < n - J_\ell$.*

Proof. We begin by showing that $J_{\ell+1} - 2^\ell = 2^\ell - J_\ell$. We have

$$\begin{aligned} J_{\ell+1}-2^\ell &= \frac{2^{\ell+2}+(-1)^{\ell+1}}{3}-2^\ell \\ &= 2^\ell-\frac{2^{\ell+1}+(-1)^\ell}{3} \\ &= 2^\ell-J_\ell, \end{aligned}$$

and hence

$$\begin{aligned} 2(n-2^\ell) &= n-2^\ell+n-2^\ell \\ &< n-2^\ell+J_{\ell+1}-2^\ell \\ &= n-2^\ell+2^\ell-J_\ell \text{ from the above argument} \\ &= n-J_\ell \end{aligned}$$

so we have our result. □

We are now ready to prove our theorem.

Theorem 5.10. *$A(n)$ is even if n is not a Jacobsthal number.*

Proof. Our goal is to show that there is some k such that $N_k^\#(n)$ is strictly greater than $D_k^\#(n)$ since, by Remark 5.5, we have shown that $N_k^\#(n) \geq D_k^\#(n)$ for all positive integers k and n.

Given n, not a Jacobsthal number, there exists a positive integer ℓ such that $J_\ell < n < J_{\ell+1}$. Then $N_{\ell+1}^\#(n) = n - J_\ell$ by Proposition 5.6, and since $n > J_\ell$, $N_{\ell+1}^\#(n) > 0$. On the other hand, by Proposition 5.7, if $n < 2^\ell$, then $D_{\ell+1}^\#(n) = 0$. If $2^\ell \leq n < J_{\ell+1}$, then by Proposition 5.8, $D_{\ell+1}^\#(n) = 2(n-2^\ell)$ which is strictly less than $n - J_\ell = N_{\ell+1}^\#(n)$ by Proposition 5.9. Hence, in every case, $N_{\ell+1}^\#(n)$ is strictly greater than $D_{\ell+1}^\#(n)$ so there is at least one factor of two in $A(n)$ and we have our result. □

6 A Closing Remark

We close by noting that we can prove a stronger result than Theorem 5.10. If $J_\ell < n < J_{\ell+1}$, then

$$N_{\ell+1}^\#(n) - D_{\ell+1}^\#(n) = \begin{cases} n - J_\ell & \text{if} \quad J_\ell < n \leq 2^\ell \\ J_{\ell+1} - n & \text{if} \quad 2^\ell \leq n < J_{\ell+1} \end{cases}$$

by Propositions 5.6, 5.7, 5.8 and Lemma 3.2.

Let $ord_2(n)$ be the highest power of 2 that divides n. By Remark 5.5, $N_k^\#(n) - D_k^\#(n) \geq 0$ for all n and for all k, so that

$$ord_2(A(n)) \geq \begin{cases} n - J_\ell & \text{if} \quad J_\ell < n \leq 2^\ell \\ J_{\ell+1} - n & \text{if} \quad 2^\ell \leq n < J_{\ell+1} \end{cases},$$

which strengthens Theorem 5.10.

Finally, we see that $ord_2(A(2^\ell)) = J_{\ell-1}$ since, for all $k < \ell+1, N_k^\#(2^\ell) = N_k^{\#(1)}(2^\ell) = D_k^{\#(1)}(2^\ell) = D_k^\#(2^\ell)$, and $2^\ell - J_\ell = J_{\ell+1} - 2^\ell = J_{\ell-1}$. So, for example, we know that $A(2^{10})$ is divisible by 2^{J_9}, which equals 2^{341}, and that $A(2^{10})$ is not divisible by 2^{342}.

Abstract: Sequences of generalized Stirling numbers of both kinds are introduced. These sequences of triangles (i.e. infinite-dimensional lower triangular matrices) of numbers will be denoted by *S2*(*k;n,m*) and *S1*(*k;n,m*) with *k* in **Z**. The original Stirling number triangles of the second and first kind arise when *k* = 1. *S2*(2;*n,m*) is identical with the unsigned *S1*(2;*n,m*) triangle, called *S1p*(2;*n,m*), which also represents the triangle of signless Lah numbers. Certain associated number triangles, denoted by *s2*(*k;n, m*) and *s1*(*k;n,m*), are also defined. Both *s2*(2;*n,m*) and *s1*(2;*n* + 1, *m* + 1) form Pascal's triangle, and *s2*(-1,*n,m*) turns out to be Catalan's triangle. Generating functions are given for the columns of these triangles. Each **S2**(*k*) and **S1**(*k*) matrix is an example of a Jabotinsky matrix. Therefore the generating functions for the rows of these triangular arrays constitute exponential convolution polynomials. The sequences of the row sums of these triangles are also considered. These triangles are related to the problem of obtaining finite transformations from infinitesimal ones generated by $x^k\, d/dx$, for *k* in **Z**.

Abstract

Sequences of generalized Stirling numbers of both kinds are introduced. These sequences of triangles (i.e. infinite-dimensional lower triangular matrices) of numbers will be denoted by $S2(k;n,m)$ *and* $S1(k;n,m)$ *with* $k \in \mathbf{Z}$. *The original Stirling number triangles of the second and first kind arise when* $k=1$. $S2(2;n,m)$ *is identical with the unsigned* $S1(2;n,m)$ *triangle, called* $S1p(2;n,m)$, *which also represents the triangle of signless Lah numbers. Certain associated number triangles, denoted by* $s2(k;n,m)$ *and* $s1(k;n,m)$, *are also defined. Both* $s2(2;n,m)$ *and* $s1(2;n+1,m+1)$ *form Pascal's triangle, and* $s2(-1,n,m)$ *turns out to be Catalan's triangle.*

Generating functions are given for the columns of these triangles. Each $\mathbf{S2}(k)$ *and* $\mathbf{S1}(k)$ *matrix is an example of a Jabotinsky matrix. The generating functions for the rows of these triangular arrays therefore constitute exponential convolution polynomials. The sequences of the row sums of these triangles are also considered.*

These triangles are related to the problem of obtaining finite transformations from infinitesimal ones generated by $x^k \frac{d}{dx}$, *for* $k \in \mathbf{Z}$.

1 Overview

Stirling's numbers of the second kind (also called *subset numbers*), and denoted by $S2(n,m)$ (or $\left\{ \begin{array}{c} n \\ m \end{array} \right\}$ in the notation of [3], or $\mathcal{S}_n^{(m)}$ in [1], or A008277 in the data-base [10]) can be defined by

$$E_x{}^n \equiv (x\,d_x)^n \;=\; \sum_{m=1}^{n} S2(n,m)\, x^m\, d_x{}^m \quad , \quad n \in \mathbf{N}, \tag{1}$$

[1] In memory of my mother Else Gertrud Lang.

where the derivative operator $d_x \equiv \frac{d}{dx}$, and E_x is the *Euler* operator satisfying $E_x\, x^k \;=\; k\, x^k$. A recursion relation can be derived from eq. 1 by considering $x\, d_x (x\, d_x)^{n-1}$, using the convention $S2(n,m) = 0$ if $n < m$ to interpret $S2(n,m)$ as a lower triangular, infinite-dimensional matrix **S2**:

$$S2(n,m) \;=\; m\, S2(n-1,m) \;+\; S2(n-1,m-1), \tag{2}$$

with initial values $S2(n,0) \equiv 0$ and $S2(1,1) = 1$. Because of eq. 1 these numbers arise when one asks how finite scale transformations (dilations) look, given infinitesimal ones. This is a special case of the exponentiation operation for Lie groups. The generator of the abelian Lie group of scale transformations $x' = \lambda\, x$, $\lambda \in \mathbf{R}_+$, is E_x. In order to exhibit these numbers within this framework consider first

$$\begin{aligned} e^{c\, x\, d_x} \;&=\; \sum_{n=0}^{\infty} \frac{c^n}{n!}\, {E_x}^n \;=\; 1 + \sum_{n=1}^{\infty} \frac{c^n}{n!} \sum_{m=1}^{n} S2(n,m)\, x^m\, {d_x}^m \\ &=\; 1 + \sum_{m=1}^{\infty} \left(\sum_{n=m}^{\infty} \frac{c^n}{n!}\, S2(n,m) \right) x^m\, {d_x}^m \;=\; 1 + \sum_{m=1}^{\infty} G2_m(c)\, x^m\, {d_x}^m \;. \end{aligned} \tag{3}$$

In the third step an interchange of summation has been performed (we ignore questions of convergence here), and in the last step an exponential generating function (e.g.f.) has been introduced for the $m-$th column of the number triangle, or lower triangular matrix, **S2**. The recursion relation implies $G2_m(c) = \frac{1}{m!}\, (G2(c))^m$, with $G2(c) = exp(c) - 1$; therefore we obtain

$$e^{c\, x\, d_x} \;=\; \sum_{m=0}^{\infty} \frac{1}{m!}\, (G2(c)\, x)^m\, {d_x}^m \;=: e^{(exp(c)-1) x\, d_x} :\,, \tag{4}$$

where we have used the linear normal order symbol $: A :$ from quantum physics. $(: A :$ means expand A in powers of x and d_x, and move all operators d_x to the right-hand side, ignoring the usual commutation rule $[d_x, x] \equiv d_x\, x - x\, d_x = 1$. For example, $: (x\, d_x)^m : \;=\; x^m\, d_x^m .)$ This normal order prescription is applied to each term of the expanded exponential in eq. 4. From Taylor's theorem, we see that for suitable functions f we have

$$e^{c\, x\, d_x}\, f(x) \;=: e^{(exp(c)-1) x\, d_x} :\, f(x) \;=\; f(x + (e^c - 1)x) \;=\; f(x') \;\;, \tag{5}$$

with $x' = e^c\, x$. Therefore the parameter λ for finite scale transformations is $\lambda = e^c$ if c is the parameter for infinitesimal transformations. In the context of Lie groups this fact is found by integrating the ordinary differential equation (see for example [2] and the references given there):

$$\frac{dx(\alpha)}{d\alpha} \;=\; c\, x(\alpha), \tag{6}$$

for curves starting at a fixed $x := x(\alpha = 0)$. The finite transformation maps x to $x' := x(\alpha = 1)$. x' should not be confused with a derivative. In this work we will generalize this to the case $E_{k;x} \equiv x^k\, d_x$ with $k \in \mathbf{Z}$. It is clear from the solution of the differential equation

$$\frac{dx(\alpha)}{d\alpha} \;=\; c\, x^k(\alpha), \quad \text{with initial condition} \;\; x(\alpha = 0) \;=: x \;\; \text{and its transform} \;\; x' := x(\alpha = 1), \tag{7}$$

that the scale transformation case $k = 1$ which has been treated above is special. For $k \neq 1$, after separation of variables, we obtain the equation $(x')^{1-k} \;-\; x^{1-k} \;=\; (1-k)\, c$. Setting

$$x' \;=\; (1 + g(k;c;x))\, x \tag{8}$$

we have

$$1 + g(k;c;x) \;=\; \left(1 - (k-1)\, c\, x^{k-1}\right)^{-\frac{1}{k-1}} \;. \tag{9}$$

Therefore

$$e^{c\,x^k\,d_x}\,f(x) \;=\; f(x') \;=\; f\left((1-(k-1)\,c\,x^{k-1})^{-\frac{1}{k-1}}\,x\right) \tag{10}$$

for $k \in \mathbf{Z}\setminus\{1\}$. The case $k=1$ has been dealt with in eq. 5. It can be recovered from eq. 10 by taking the limit $k-1\to 0$.

$k-$Stirling numbers of the second kind, which we will denote by $S2(k;n,m)$, with $S2(1;n,m)=S2(n,m)$ the ordinary Stirling subset numbers, emerge in a proof, independent of the one implied by eq. 10, of the following operator identity, valid for $k\in\mathbf{Z}$,

$$e^{c\,x^k\,d_x} \;=:\, e^{g(k;c;x)\,x\,d_x}\,:\;, \tag{11}$$

where $g(k;c;x)$ is defined by eq. 9 for $k\neq 1$ and $g(1;c;x)=G2(c)$ (see eq. 4). By analogy with eq. 1 the $S2(k;n,m)$ number triangle is defined by

$$E_{k;x}{}^n \equiv (x^k\,d_x)^n \;=\; \sum_{m=1}^{n} S2(k;n,m)\,x^{m+(k-1)\,n}\,d_x{}^m \quad,\quad n\in\mathbf{N},\quad k\in\mathbf{Z}\;, \tag{12}$$

with the further convention that $S2(k;n,m)=0$ for $n<m$ and $S2(k;n,0)=0$. These numbers will be shown to satisfy the recursion relation

$$S2(k;n,m) \;=\; ((k-1)(n-1)+m)\,S2(k;n-1,m) \;+\; S2(k;n-1,m-1), \tag{13}$$

with $S2(k;1,1)=1$ from eq. 12. The e.g.f. for the $m-$th column of the $\mathbf{S2}(k)$ triangle,

$$G2(k;m;x) \;:=\; \sum_{n=m}^{\infty} S2(k;n,m)\,\frac{x^n}{n!}\;, \tag{14}$$

satisfies

$$G2(k;m;x) \;=\; \frac{1}{m!}\,(G2(k;x))^m \tag{15}$$

for $k\neq 1$, with

$$G2(k;x) \;=\; (k-1)\,g2(k;\frac{x}{k-1})\;, \tag{16}$$

where

$$g2(k;y) \;:=\; \sum_{n=1}^{\infty} s2(k;n,1)\,y^n \tag{17}$$

is the ordinary generating function (o.g.f.) for the first column of the triangle of numbers $s2(k;n,m)$ which is associated to triangle $S2(k;n,m)$ by[2]

$$s2(k;n,m) \;:=\; (k-1)^{n-m}\,\frac{m!}{n!}\,S2(k;n,m)\;. \tag{18}$$

These number triangles, or lower triangular infinite-dimensional matrices, $\mathbf{s2}(k)$, which are here only defined for $k\in\mathbf{Z}\setminus\{1\}$, obey the recursion relation

$$s2(k;n,m) \;=\; \frac{k-1}{n}\,[(k-1)(n-1)+m]\;s2(k;n-1,m) \;+\; \frac{m}{n}\,s2(k;n-1,m-1) \quad, \tag{19}$$

with

$$s2(k;n,m) \;=\; 0,\; n<m \quad,\quad s2(k;n,0) \;=\; 0,\quad s2(k;1,1)=1\;. \tag{20}$$

[2]These *associated Stirling numbers of the second kind* are not the ones of [5], p. 76, Table 2.

It follows that these numbers are nonnegative. At this stage it is not obvious that they are integers for every $k \in \mathbf{Z} \setminus \{1\}$.
The o.g.f. of the m-th column of the $\mathbf{s2}(k)$ matrix is

$$g2(k;m;y) \;:=\; \sum_{n=m}^{\infty} s2(k;n,m)\, y^n \;=\; (g2(k;y))^m \;, \tag{21}$$

with

$$g2(k;y) \;=\; y\, c2(1-k;y), \tag{22}$$

and, for $l \in \mathbf{Z} \setminus \{0\}$,

$$c2(l;y) \;=\; \frac{1-(1-l^2\, y)^{\frac{1}{l}}}{l\, y} \;. \tag{23}$$

It is clear from eq. 21 that $\mathbf{s2}(k)$ is a convolution triangle generated from its first column (cf. [4],[6],[9]). Such ordinary convolution triangles will be called *Bell* matrices [9] (see Note 7). For $k \in \mathbf{Z} \setminus \{1\}$, eq. 16 now yields

$$G2(k;x) \;=\; -1 \;+\; (1+(1-k)\, x)^{\frac{1}{1-k}} \;, \tag{24}$$

and letting $k-1 \to 0$ we obtain $G2(1;x) \;=\; e^x - 1 \;=\; G2(x)$. The infinite-dimensional lower triangular matrices $\mathbf{S2}(k)$ with integer entries are examples of *Jabotinsky* matrices (*cf.* [4], which also contains earlier references). Therefore the o.g.f. of the rows of the triangle $\mathbf{S2}(k)$ are exponential (or binomial) convolution polynomials. In other words, the polynomials

$$S2_n(k;x) \;:=\; \sum_{m=1}^{n} S2(k;n,m)\, x^m \quad , \quad S2_0(k;x) := 1 \;, \tag{25}$$

satisfy

$$S2_n(k;x+y) \;=\; \sum_{p=0}^{n} \binom{n}{p} S2_p(k;x)\, S2_{n-p}(k;y) \;=\; \sum_{p=0}^{n} \binom{n}{p} S2_p(k;y)\, S2_{n-p}(k;x) \tag{26}$$

for $k \in \mathbf{Z}$. In the notation of the umbral calculus (*cf.* [7]) the polynomials $S2_n(k;x)$ are a special type of *Sheffer* polynomials called *associated polynomial sequences*. An equivalent notation used there for the general case is "Sheffer for $(1, f(t))$". In our case $f(t) \;=\; \overline{G2(k;t)}$, where $\overline{G2(k;t)} \;=\; (-1+(1+t)^{1-k})/(1-k)$ if $k \neq 1$. This is the compositional inverse of $G2(k;t)$ from eq. 24. Also $\overline{G2(1;t)} = ln(1+t)$ can be obtained in the limit as $1-k \to 0$.
For negative k the $\mathbf{S2}(k)$ matrices also contain negative entries. The recursion of eq. 13 shows that it is possible to define nonnegative matrices by

$$S2p(-k;n,m) \;:=\; (-1)^{n-m}\, S2(-k;n,m) \quad , \quad k \in \mathbf{N}_0. \tag{27}$$

The e.g.f. for column m of the triangle $\mathbf{S2}p(-|k|)$ is

$$G2p(-|k|;m;x) \;=\; \frac{1}{m!}\, (G2p(-|k|;x))^m \tag{28}$$

with

$$G2p(-|k|;x) \;=\; -\, G2(-|k|;-x) \;=\; 1 \;-\; (1-(|k|+1)\, x)^{\frac{1}{|k|+1}}. \tag{29}$$

Eqs. 19 and 20 will be seen to imply that the $\mathbf{s2}(-|k|)$ matrices have always nonnegative entries. In Tables 1 and 2 we have listed for some of these $\mathbf{s2}(k)$ and $\mathbf{S2}(k)$ triangles the A-numbers under which they can be viewed in the on-line data-base [11] (see also [10]). This data-base will henceforth be quoted as *EIS*

(Encyclopedia of Integer Sequences). These tables also give the A-numbers of the sequences formed by the first columns of the lower triangular matrices, and of the sequences of the row sums of these matrices.
For $l = 2$ the function $c2(l; y)$ defined in eq. 23 generates the well-known *Catalan* numbers. For $l \in \mathbf{Z} \setminus \{0\}$ it defines what we call $l-Catalan$ numbers. For positive l these sequences were introduced by O. Gerard in *EIS*, who called them *Patalan* numbers. It will be proved later (see Note 11) that $c2(l; y)$ does indeed generate integers. Their explicit form can be found in eq. 77.

The *Stirling numbers of the first kind*, $S1(n, m)$ ($S_n^{(m)}$ in [1], *EIS*: A008275), can be defined from the inversion of eq. 1 by

$$x^n \, d_x{}^n \;=\; \sum_{m=1}^{n} S1(n,m)\,(x\,d_x)^m \quad . \tag{30}$$

We also set $S1(n, 0) \equiv 0$ and $S1(n, m) := 0$ for $n < m$. In (infinite-dimensional) matrix notation we can write [4]

$$\mathbf{S1}\cdot\mathbf{S2} \;:=\; \mathbf{1} \;=\; \mathbf{S2}\cdot\mathbf{S1} \quad . \tag{31}$$

The *signless Stirling numbers of the first kind*, also known as *cycle numbers*, $S1p(n, m)$ (or $\left[\begin{array}{c} n \\ m \end{array} \right]$ in the notation of [3]), are

$$S1p(n,m) \;:=\; (-1)^{n-m}\, S1(n,m) \quad . \tag{32}$$

Their recurrence formula is

$$S1p(n+1,m) \;=\; n\, S1p(n,m) \;+\; S1p(n,m-1) \quad , \tag{33}$$

with $S1p(1, 1) = 1$, $S1p(n, 0) = 0$ and $S1p(n, m) = 0$ for $n < m$.

The *generalized $k-$Stirling numbers of the first kind* $S1(k; n, m)$ are defined analogously by inverting eq. 12, *i.e.*

$$x^{kn}\, d_x{}^n \;=\; \sum_{m=1}^{n} S1(k;n,m)\, x^{(k-1)(n-m)}\,(x^k\, d_x)^m \quad \text{for} \quad k \in \mathbf{Z}\ ,\ n \in \mathbf{N}\ . \tag{34}$$

In matrix notation:

$$\mathbf{S1}(k)\cdot\mathbf{S2}(k) \;=\; \mathbf{1} \;=\; \mathbf{S2}(k)\cdot\mathbf{S1}(k) \quad \text{for} \quad k \in \mathbf{Z}. \tag{35}$$

For $k \in \mathbf{N}$ we define the *nonnegative $k-$Stirling numbers of the first kind* by

$$S1p(k;n,m) \;:=\; (-1)^{n-m}\, S1(k;n,m)\ . \tag{36}$$

For $-k \in \mathbf{N}_0$ the numbers $S1(k; n, m)$ are nonnegative.
The recurrence relation for $k-$Stirling numbers of the first kind is

$$S1(k;n,m) \;=\; -[(k-1)\,m + n - 1]\, S1(k;n-1,m) \;+\; S1(k;n-1,m-1) \quad , \tag{37}$$

with $S1(k; 1, 1) = 1$, $S1(k; n, 0) = 0$ and $S1(k; n, m) = 0$ for $n < m$. For $k \neq 1$ we also introduce the *associated $k-$Stirling numbers of the first kind* [3]

$$s1(k;n,m) \;:=\; (1-k)^{n-m}\, \frac{m!}{n!}\, S1(k;n,m)\ , \tag{38}$$

which turn out to be always nonnegative. They satisfy the recursion

$$s1(k;n,m) \;=\; \frac{k-1}{n}\big((k-1)\,m + n - 1\big)\, s1(k;n-1,m) + \frac{m}{n}\, s1(k;n-1,m-1) \tag{39}$$

[3] These associated Stirling numbers of the first kind are not the ones appearing in [5], p. 75, table 2.

with $s1(k;n,m) = 0$ for $n < m$, $s1(k;1,1) = 1$ and $s1(k;n,0) := 0$. At this stage it is not obvious that the $s1(k;n,m)$ are in fact integers.
The o.g.f. for the $m-$th column of the number triangle $s1(k;n,m)$ will be shown to be

$$g1(k;m;y) \;=\; \sum_{n=m}^{\infty} s1(k;n,m)\, y^n \;=\; (g1(k;y))^m \;, \tag{40}$$

for $k \in \mathbf{Z} \setminus \{1\}$, with

$$g1(k;y) \;=\; y\, c1(k-1;y), \tag{41}$$

and, for $l \in \mathbf{Z} \setminus \{0\}$,

$$c1(l;y) \;=\; \frac{-1 \;+\; (1-l\,y)^{-l}}{l^2\, y} \;. \tag{42}$$

Hence $\mathbf{s1}(k)$ is, like $\mathbf{s2}(k)$, a convolution triangle generated from its $m = 1$ column, *i.e.* both are Bell matrices.
For $l \in \mathbf{N}$ the function $c1(l;y)$ generates the numbers

$$c1(l;y) \;=\; \sum_{n=0}^{\infty} c1_n^{(l)}\, y^n \;, \quad c1_n^{(l)} \;=\; \binom{n+l}{l-1}\, l^{n-1} \;. \tag{43}$$

For $l = 2$ this is the *EIS* sequence A001792 $\{1, 3, 8, 20, 48, ...\}$. For negative l, $c1(l;y)$ becomes a polynomial in y; *e.g.* $c1(-2;y) = 1 + y$, or $g1(-1;y) = y + y^2$. The coefficients of these polynomials define a triangle of numbers found under the *EIS* number A049323. Their explicit form is, for $l \in \mathbf{N}$,

$$c1_n^{(-l)} \;=\; \binom{l}{n+1}\, l^{n-1} \quad \text{for } n = 0, 1, ..., l-1, \text{ and 0 otherwise.} \tag{44}$$

Eq. 43 now implies, using eqs. 41 and 40, that $s1(k;n,m)$ is indeed an integer for every $k \in \mathbf{Z} \setminus \{1\}$. An explicit form for the entries in the first column is

$$s1(k;n,1) \;=\; \begin{cases} \binom{k-2-n}{k-2}\, (k-1)^{n-2} & \text{for } k = 2, 3, ..., \text{and } n \in \mathbf{N} \\ \\ \binom{|k|+1}{n}\, (|k|+1)^{n-2} & \text{for } -k \in \mathbf{N}_0\,,\; n = 1, 2, ...|k|+1\;. \end{cases} \tag{45}$$

The e.g.f.s for the $m-$th column of the signless $k-$Stirling numbers of the first kind are then, for $k = 2, 3, ...$,

$$G1p(k;m;x) \;:=\; \sum_{n=m}^{\infty} S1p(k;n,m)\, \frac{x^n}{n!} \;, \tag{46}$$

$$\;=\; \frac{1}{m!} \left[(k-1)\, g1(k; \frac{x}{k-1}) \right]^m \;. \tag{47}$$

The case $k = 1$ corresponds to the ordinary unsigned Stirling numbers $S1p(n,m)$ with e.g.f. for column m given by $G1p(1;m;x) \;=\; \frac{1}{m!} \left(-ln(1-x)\right)^m$. From eqs. 47, 41 and 42,

$$G1p(k;1;x) \;=\; (k-1)\, g1(k; \frac{x}{1-x}) \;=\; \frac{1}{k-1} \left(-1 \;+\; \frac{1}{(1-x)^{k-1}}\right) \;, \tag{48}$$

and we recover the result for $k = 1$ from l'Hôpital's rule in the limit $k - 1 \to 0$. Note that $G1(k;1;x) = -G1p(k;1;-x) = \overline{G2(k;1;x)}$ for $k \in \mathbf{Z}$.
For $-k \in \mathbf{N}_0$ the e.g.f. for the $m-$th column of the nonnegative triangular matrix $\mathbf{S1}(-|k|)$ is, from eqs. 36 and 46, $G1(-|k|;m;x) \;=\; (-1)^m\, G1p(-|k|;m;-x)$, hence

$$G1(k;1;x) \;=\; \frac{1}{1+|k|} \left(-1 \;+\; (1+x)^{1+|k|}\right) \quad \text{for} \quad -k \in \mathbf{N}_0 \;. \tag{49}$$

For the signed matrix $\mathbf{S1}(-|k|)$ with elements defined by $S1s(-|k|;n,m) := (-1)^{n-m}\, S1(-|k|,n,m)$ the e.g.f. of the $m-$th column is $G1s(-|k|;m;x) = (-1)^m\, G1(-|k|;m;-x)$, *i.e.* $G1s(-|k|;x) \equiv G1s(-|k|;1;x) = (1-(1-x)^{1+|k|})/(1+|k|)$ for $k \in \mathbf{N}_0$.

Tables 3 and 4 give the *EIS* A-numbers of some of the number triangles $\mathbf{s1}(k)$, $\mathbf{S1}(k)$ and $\mathbf{S1p}(k)$. The A-numbers of the $m=1$ column and of the sequence of row sums for each triangle are also given there.

The o.g.f. of the row sequences of triangle $\mathbf{S1}(k)$ are also exponential (or binomial) convolution polynomials. In other words the polynomials

$$S1_n(k;x) := \sum_{m=1}^{n} S1(k;n,m)\, x^m \quad , \quad S1_0(k;x) := 1 \ , \quad k \in \mathbf{Z} \ , \tag{50}$$

satisfy eq. 26 with $S2$ replaced by $S1$. In the notation of the umbral calculus (*cf.* [7]) the polynomials $S1_n(k;x)$ are a special type of Sheffer polynomials called associated polynomial sequences or "Sheffer for $(1, f(t))$." Here $f(t) = \overline{G1(k;t)}$, where $\overline{G1(k;t)} = G2(k;t)$ is given, for $k \neq 1$, in eq. 24. Also $G1(1;t) = G2(1;t) = exp(t) - 1$ is obtained in the limit as $1-k \to 0$.

Each sequence of row sums of a triangle of the type considered in this work is generated by a function which depends on the generating function of the triangle's first ($m=1$) column. For the $\mathbf{s2}(k)$ and $\mathbf{s1}(k)$ triangles, which can be considered as Bell matrices, these o.g.f.s are, for $k \in \mathbf{Z} \setminus \{1\}$,

$$r2(k;x) = \frac{g2(k;x)}{1-g2(k;x)} = \frac{-1 + [1-(1-k)^2\, x]^{\frac{1}{1-k}}}{k - [1-(1-k)^2\, x]^{\frac{1}{1-k}}}, \tag{51}$$

$$r1(k;x) = \frac{g1(k;x)}{1-g1(k;x)} = \frac{1 - [1-(k-1)\, x]^{k-1}}{(1+(1-k)^2)\,[1-(k-1)\, x]^{k-1} - 1} \tag{52}$$

For the $\mathbf{S2}(k)$ ($k \in \mathbf{N}_0$) and $\mathbf{S2p}(k)$ ($-k \in \mathbf{N}_0$) triangles, which can be interpreted as Jabotinsky matrices, the e.g.f.s for the sequences of row sums are

$$R2(k;x) = e^{G2(k;x)} - 1 = exp\,[-1 + (1-(k-1)\, x)^{\frac{1}{1-k}}] - 1 \ , \tag{53}$$

$$R2p(-|k|;x) = e^{G2p(-|k|;x)} - 1 = exp\,[1 - (1-(1+|k|)\, x)^{\frac{1}{1+|k|}}] - 1 \ . \tag{54}$$

For the $\mathbf{S1p}(k)$ ($k \in \mathbf{N}_0$) and $\mathbf{S1}(k)$ ($-k \in \mathbf{N}_0$) triangles, which can also be interpreted as Jabotinsky matrices, the e.g.f.s for the sequences of row sums are

$$R1p(k;x) = e^{G1p(k;x)} - 1 = exp\Big(\frac{1}{k-1}\,[-1 + (1-x)^{\frac{1}{k-1}}]\Big) - 1 \ , \tag{55}$$

$$R1(-|k|;x) = e^{G1(-|k|;x)} - 1 = exp\Big(\frac{1}{1+|k|}[-1 + (1+x)^{1+|k|}]\Big) - 1 \ . \tag{56}$$

The special case $k=1$ can be obtained for $R2(k;x)$ and $R1p(k;x)$ by taking the limit as $k-1 \to 0$.

In Sections 2 and 3 we will give proofs of the results stated above.

2 k−Stirling numbers of the second kind

Definition 1: $S2(k;n,m)$. The *k-Stirling numbers of the second kind*, $S2(k;n,m)$, are defined for $k \in \mathbf{Z}$ by eq. 12.

Lemma 1: The numbers $S2(k;n,m)$ satisfy the recursion relation eq. 13.

Proof: Consider $(x^k\, d_x)^n = x^k\, d_x\, (x^k\, d_x)^{n-1}$ and use eq. 12 with $n \to n-1$ together with the lower triangular matrix conditions given after this eq. Then compare coefficients of $\{x^m\, {d_x}^m\}_1^n$. □

Note 1: It follows from eq. 13 and the initial conditions that the $S2(k;n,m)$ are always integers.

Definition 2: $s2(k;n,m)$. The *associated k-Stirling numbers of the second kind*, $s2(k;n,m)$, are defined for

$k \in \mathbf{Z} \setminus \{1\}$ by eq. 18.

Lemma 2: The numbers $s2(k;n,m)$ satisfy the recursion relation given by eqs. 19 and 20.

Proof: Rewrite eq. 13 for $s2(k;n,m)$. □

Note 2: That the $s2(k;n,m)$ are indeed integers will be proved much later in Lemma 19.

Note 3: For $k = 1$ eqs. 19 and 20 give the (infinite-dimensional) unit matrix $\mathbf{s2}(1) = \mathbf{1}$. This will be used as the definition of $\mathbf{s2}(1)$.

Lemma 3: Nonnegativity of $\mathbf{s2}(k)$. The entries of the lower triangular matrix $\mathbf{s2}(k)$ are nonnegative for each $k \in \mathbf{Z}$.

Proof: If $k - 1 \geq 0$ this follows from eq. 19. For $1 - k \in \mathbf{N}$ the first term in eq. 19 becomes negative if and only if $(1-k)\,(n-1) < m$ and $n - 1 \geq m$ (otherwise $s2(k;n-1,m)$ vanishes). But the first condition contradicts the second. □

Lemma 4: The o.g.f. $g2(k;m,y)$ defined in the first of eqs. 21 for the $m-$th column sequence of the lower triangular matrix $\mathbf{s2}(k)$ with $k \in \mathbf{Z} \setminus \{1\}$ satisfies the first order linear differential-difference equation

$$[1-(k-1)^2\,y]\,g2'(k;m,y) \;-\; m\,(k-1)\,g2(k;m,y) \;-\; m\,g2(k;m-1,y) \;=\; 0 \;\;, \tag{57}$$

$$g2(k;m,0) = 0 \;,\; m \in \mathbf{N};\;\; g2'(k;m,y)|_{y=0} = 0 \;,\; m \in \{2,3,...\} \;;\; g2'(k;1,y)|_{y=0} = s2(k;1,1) = 1. \tag{58}$$

The prime denotes differentiation with respect to the variable y.

Proof: Compute $y\,\frac{d}{dy}\sum_{n=m}^{\infty} n\,s2(k;n,m)\,y^n$ with the help of the recurrence relation in eqs. 19 and 20 for $y \neq 0$. For $y = 0$ the conditions given in eq. 58 follow from the definition of $g2(k;m,y)$. □

Lemma 5: Using $g2(k;m,y) \;=\; (g2(k;1,y))^m$, $g2(k;y) := g2(k;1,y)$ satisfies the first order differential equation

$$[1-(k-1)^2\,y]\,g2'(k;y) \;-\; (k-1)\,g2(k;y) \;-\; 1 \;=\; 0\;. \tag{59}$$

for $k \in \mathbf{Z} \setminus \{1\}$.

Proof: Immediate from Lemma 4. □

Lemma 6: The solution to the differential eq. 59 with initial condition $g2(k;0) = 0$ is, for $k \in \mathbf{Z} \setminus \{1\}$,

$$g2(k;y) \;=\; \frac{1}{[1-(k-1)^2\,y]^{\frac{1}{k-1}}}\;\frac{1-[1-(k-1)^2\,y]^{\frac{1}{k-1}}}{k-1} \;=:\; \frac{y}{[1-(k-1)^2\,y]^{\frac{1}{k-1}}}\,c2(k-1;y)\;. \tag{60}$$

Proof: Standard integration of a first order inhomogeneous differential equation of the form $g'(y) + f(y)\,g(y) = k(y)$. □

Note 4: *Generalized Catalan numbers.* The l-Catalan numbers (for $l \in \mathbf{Z} \setminus \{0\}$) have

$$c2(l;x) \;:=\; \frac{1-[1-l^2\,x]^{\frac{1}{l}}}{l\,x} \tag{61}$$

as o.g.f. The case $l = 2$ corresponds to the ordinary Catalan numbers (*EIS* A000108). For positive l these numbers have been called Patalan numbers by Gerard in *EIS* (*cf.* A025748-A025755 for $l = 3..10$).
That $c2(l;y)$ generates integers will follow later from the fact that $s2(k;n,m)$ is always an integer (see Notes 2 and 11). Because $c2(-l;x) \;=\; c2(l;x)/(1-l^2\,x)^{\frac{1}{l}}$, one can write $g2(k;y) \;=\; y\,c2(1-k;y)$, as stated in eq. 22.

Consider the expansion $1/(1-l^2\,x)^{1/l} \;=\; \sum_{n=0}^{\infty} b_n^{(l)}\,x^n$, where $b_n^{(l)} \;=\; l^n\,(\prod_{j=1}^{n}(j\,l+1-l))/n!$ and $b_0^{(l)} \;=\; 1$, $n \geq 1$. Therefore the sequence $\{c2_n^{(-l)}\}_{n=0}^{\infty}$ generated by $c2(-l;x)$ for $l \in \mathbf{N}$ is the (ordinary) convolution of

the sequence $\{b_n^{(l)}\}_{n=0}^{\infty}$ with the sequence $\{c2_n^{(l)}\}_{n=0}^{\infty}$. See *e.g.* *EIS* A035323 for $l = -10$.

Since we have put $\mathbf{s2}(1) = \mathbf{1}$ we take $g2(1;y) = y$.

Lemma 7: The e.g.f. for the m-th column sequence of the $k-$Stirling triangle of the second kind $\mathbf{S2}(k)$, defined in eq. 14, is $G2(k;m;x) = \frac{1}{m!}\,(G2(k;1;x))^m$, $m \in \mathbf{N}$, with $G2(k;1;x) \equiv G2(k;x) = (k-1)\,g2(k;\frac{x}{k-1})$ for $k \neq 1$ and $G2(1;1;x) \equiv G2(1;x) = exp(x) - 1$.

Proof: For $k \neq 1$ substitute $S2(k;n,m)$ from eq. 18 into the definition of $G2(k;m;x)$, and then use eq. 21. For the ordinary Stirling numbers, *i.e.* for $k = 1$, the stated result is well-known [1]. □

Lemma 8: For $k \in \mathbf{Z} \setminus \{1\}$,

$$e^{c\,x^k\,d_x} = \sum_0^{\infty} \frac{1}{m!}\left[g2(k;\frac{c}{k-1}\,x^{k-1})\,(k-1)\,x\right]^m d_x^{\,m} = :\, e^{g(k;c;x)\,x\,d_x} :\,, \tag{62}$$

where $g(k;c;x) := g2(k;\frac{c}{k-1}\,x^{k-1})\,(k-1)$, and the normal order $: A :$ notation has been explained in the paragraph following eq. 4.

Proof: Similar to that for ordinary Stirling numbers of the second kind, as explained in Section 1, eqs. 3 and 4. Expand the exponential and insert the definition of $S2(k;n,m)$ from eq. 12 using the triangle convention stated there. Then exchange the row summation with the column summation (ignoring questions of convergence). After replacing $S2(k;n,m)$ by $s2(k;n,m)$, using eq. 18 (and remembering that $k \neq 1$) we find the o.g.f. $g2(k;m;\frac{c}{k-1}\,x^{k-1})$ inside the column summation. The convolution property eq. 21 (Lemmas 4,5 and 6) then yields the first eq. of the lemma. The second follows from the definition of normal order, which is applied to each term in the expanded exponential. □

Note 5: For $k \neq 1$, if we insert the o.g.f. $g2(k;y)$ given in Lemma 6, or eqs. 22 and 23, we obtain the formula for $g(k;c;x)$ given in eq. 9. For $k = 1$ we obtain $g(1;c;x) = exp(c) - 1$ from eq. 5.

Corollary 1: The operator identity in eq. 11, proved in Lemma 8, implies the shift property shown in eq. 10.

Proof: An applicaton of Taylor's theorem. □

Note 6: A third proof of the shift property in eq. 10 can be given by using the well-known multiple commutator formula for $exp\,(\mathbf{B})\,x^l\,exp(-\mathbf{B})$ for $l \in \mathbf{N}_0$, setting the operator $\mathbf{B} = c\,E_{k;x} = c\,x^k\,d_x$ for $k \in \mathbf{Z}$ and the commutator $[E_{k;x}, x^l] = l\,x^{l+k-1}$. For $k = 1$ we find $exp(c\,x\,d_x)\,x^l\,1 = (exp(c)\,x)^l\,exp(c\,x\,d_x)\,1 = (exp(c)\,x)^l$. For $k \neq 1$ we first obtain $exp(c\,E_{k;x})\,x^l\,exp(-c\,E_{k;x}) = \sum_{n=0}^{\infty}\frac{1}{n!}(l/(k-1))_n\,(c\,(k-1)\,x^{k-1})^n$ using the rising factorial (or *Pochhammer*) symbol $(\nu)_n := \nu\,(\nu+1)\cdots(\nu+n-1)$. This implies $exp(c\,x^k\,d_x)\,x^l\,1 = [(1+g(k;c;x))\,x]^l\,1$ with $1+g(k;c;x)$ given in eq. 9. The 1 on the right-hand side stands for any $x-$independent operator or function. Hence the shift property eq. 10 holds for polynomials and (formally) for power series $f(x)$.

Lemma 9: For $k \in \mathbf{Z}$ the e.g.f. of the row polynomials $S2_n(k;x)$ defined in eq. 25, $\mathcal{G}2(k;z,x) := \sum_{n=0}^{\infty} S2_n(k;x)\,z^n/n!$, is given by

$$\mathcal{G}2(k;z,x) = e^{x\,G2(k;z)}\,, \tag{63}$$

where $G2(k;z)$ is the e.g.f. for the first $(m = 1)$ column sequence of the triangular matrix $\mathbf{S2}(k)$ given in eq. 24.

Proof: Separate the $n = 0$ term in the definition of $\mathcal{G}2(k;z,x)$ and insert in the remaining expression the definition of the row polynomials eq. 25. Then interchange the row and column summation indices and use the definition of the e.g.f. $G2(k;m;z)$ given in eq. 14. The convolution property Lemma 7, or eq. 15, then leads to the desired result. □

Note 7: Another way to state Lemma 9 is to write

$$S2(k;n,m) = \left[\frac{z^n}{n!}\right]\,[x^m]\,e^{x\,G2(k;z)}\,, \tag{64}$$

where $[y^k]\, f(y)$ denotes the coefficient of y^k in the expansion of $f(y)$. For each $k \in \mathbf{Z}$ a matrix constructed in this way from the entries of its first $(m = 1)$ column (collected in the e.g.f. $G2(k; z)$) is called a Jabotinsky matrix. (See [4] for references to the original works. Note that we use Knuth's $n!\, F_n(x)$ as row (or Jabotinsky) polynomials. Knuth's $f(z)$ corresponds to our e.g.f. for the $m = 1$ column sequence.)

Another notation is used in the umbral calculus (*cf.* [7]). The row polynomials $E_n(x) = \sum_{n=1}^{m} J(n, m)\, x^n$ built from a lower triangular Jabotinsky matrix $J(n, m)$ are there called associated polynomial sequences. Their defining function is the compositional inverse of the e.g.f. $f(t)$ used by Knuth and in the present work (*cf.* [7], p. 53). $\{E_n(x)\}$ are special Sheffer polynomials for $(1, \bar{f}(t))$ in the umbral notation (*cf.* [7], p. 107).

Yet another description of such convolution polynomials can be found in [9], where Jabotinsky matrices appear as a special case of so-called *Riordan* matrices (if one uses exponential generating functions). The corresponding matrix product furnishes a so-called *Bell* subgroup of the Riordan group (*cf.* [9], p. 238). In the sequel we shall reserve the names Riordan and Bell matrices for the case of ordinary convolutions.

Lemma 10: The exponential (or binomial) convolution property given in eq. 26 for polynomials $S2_n(k; x), n \in \mathbf{N}_0$ and fixed k, is equivalent to the functional equation

$$\mathcal{G}2(k; z, x + y) \;=\; \mathcal{G}2(k; z, x)\, \mathcal{G}2(k; z, y)\ , \tag{65}$$

which follows from eq. 63 for the e.g.f. $\mathcal{G}2(k; z, x)$ defined in Lemma 9.

Proof: Fix k and compare the coefficients of $z^n/n!$ on both sides of this equation. □

Proposition 1: Exponential convolution property of the $S2_n(k; x)$ polynomials. The row polynomials $S2_n(k; x)$ defined in eq. 25 for $n \in \mathbf{N}_0$ satisfy for each $k \in \mathbf{Z}$ the exponential convolution property shown in eq. 26.

Proof: Lemma 10 with Lemma 9. □

Lemma 11: Row sums of ordinary convolution matrices [6]. The o.g.f. $r(x) := \sum_{n=1}^{\infty} r_n\, x^n$ of the row sums $r_n := \sum_{m=1}^{n} s(n, m)$ of a lower triangular ordinary convolution matrix $\{s(n, m)\}_{n \geq m \geq 1}$ is given by

$$r(x) \;:=\; \frac{g(x)}{1 - g(x)}\ , \tag{66}$$

where $g(x)$ is the o.g.f. of the first $(m = 1)$ column of the matrix $s(n, m)$.

Proof: Consider a lower triangular convolution matrix. By definition, the o.g.f. $g(m; x)$ for its $m-$th column sequence is given by $g(m; x) = (g(1; x))^m = g(x)^m$ for $m \in \mathbf{N}$. The result follows by inserting into $r(x)$ the definition of the row sums r_n, interchanging row and column summation indices and using the definition and convolution property of $g(m; x)$. □

Lemma 12: Row sums of exponential convolution matrices. The e.g.f. $R(x) := \sum_{n=1}^{\infty} R_n\, x^n/n!$ of the row sums $R_n := \sum_{m=1}^{n} S(n, m)$ of a lower triangular exponential convolution matrix $\{S(n, m)\}_{n \geq m \geq 1}$ is given by

$$R(x) \;:=\; e^{G(x)} \;-\; 1\ , \tag{67}$$

where $G(x)$ is the e.g.f. of the first $(m = 1)$ column sequence of the matrix $\{S(n, m)\}_{n \geq m \geq 1}$.

Proof: Analogous to the proof of Lemma 11. □

Proposition 2: O.g.f. for row sums of the $\mathbf{s2}(k)$ triangles. For $k \in \mathbf{Z} \setminus \{1\}$ the o.g.f. of the sequence of row sums of the lower triangular matrix $\mathbf{s2}(k)$ is given by eq. 51.

Proof: Lemma 11 and the $g2(k; x)$ result from Lemma 6, eq. 60. □

Proposition 3: E.g.f. for the sequence of row sums of the $\mathbf{S2}(k)$ and $\mathbf{S2p}(k)$ triangles. For $k \in \mathbf{N_0}$ the e.g.f. of the sequence of row sums of the nonnegative lower triangular matrix $\mathbf{S2}(k)$, resp. $\mathbf{S2p}(k)$, defined

from eq. 13, resp. eq. 27, is given by eq. 53, resp. eq. 54.

Proof: Lemma 12 and $G2(k;x)$, resp. $G2p(-k;x)$, from eq. 24, resp. eq. 29. □

3 k−Stirling numbers of the first kind

$k-$Stirling numbers of the first kind can be defined as the elements of the (infinite-dimensional, lower triangular) inverse matrix $\mathbf{S1}(k)$ to the matrix $\mathbf{S2}(k)$ formed from the $k-$Stirling numbers of the second kind.

Definition 3: *$k-$Stirling numbers of the first kind*, $S1(k;n,m)$, are defined by

$$x^n\, d_x{}^n \;=\; \sum_{m=1}^{n} S1(k;n,m)\, x^{-m(k-1)}\, (x^k\, d_x)^m \quad , \text{ for } k \in \mathbf{Z},\ n \in \mathbf{N}\ . \tag{68}$$

Note that this equation is obtained from eq. 34 by multiplication by $x^{-n(k-1)}$ on the left. Therefore the equations are equivalent for every k provided $x \neq 0$. We set $S1(k;n,m) \;=\; 0$ if $n < m$, *i.e.* $\mathbf{S1}(k)$ is a lower triangular matrix.

Lemma 13: $\mathbf{S2}(k)\ \cdot \mathbf{S1}(k) \;=\; \mathbf{1}$, or

$$\sum_{m=p}^{n} S2(k;n,m)\, S1(k;m,p) \;=\; \delta_{n,p} \tag{69}$$

for fixed $k \in \mathbf{Z}$, $n \in \mathbf{N}$ and $p \in \mathbf{N}$, where $\delta_{n,p}$ is the Kronecker symbol.

Proof: Insert eq. 68 with $n \to m$ and $m \to p$ into the defining eq. 12 for the $S2(k;n,m)$ numbers, and then extend the $p-$sum from m to n, using lower triangularity of each matrix $\mathbf{S1}(k)$. After interchanging the summations over m and p we find, for all $k \in \mathbf{Z}$, $n \in \mathbf{N}$ and $x \neq 0$,

$$\mathcal{O}_x(k;n) \;:=\; x^{-(k-1)n}\, (x^k\, d_x)^n \;=\; \sum_{p=1}^{n} \delta(k;n,p)\, \mathcal{O}_x(k;p)\ , \tag{70}$$

with $\delta(k;n,p) \;:=\; \sum_{m=p}^{n} S2(k;n,m)\, S1(k;m,p)$. Since the operators $\{\mathcal{O}_x(k;p)\}_{p=1}^{n}$ acting on functions $f \in C^n$ are a linearly independent[4], eq. 70 implies $\delta(k;n,p) = \delta_{n,p}$ for each k. □

Similarly, one finds

$$\mathbf{S1}(k)\ \cdot \mathbf{S2}(k) \;=\; \mathbf{1} \tag{71}$$

after inserting eq. 12 with $n \to m$, $m \to p$ into eq. 68. Now we compare coefficients of the operators $\{x^p\, d_x{}^p\}_1^n$.

Lemma 14: The $k-$Stirling numbers of the first kind satisfy the recurrence given in eq. 37.

Proof: Use $x^n\, d_x{}^n \;=\; (x\, d_x - (n-1))\, x^{n-1}\, d_x{}^{n-1}$ and insert eq. 68 in both sides of this identity. After differentiation, remembering the triangularity of $\mathbf{S1}(k)$, we compare coefficients of the linearly independent operators $\{\mathcal{O}_x(k;m)\}_{m=1}^{n}$ defined in eq. 70. □

Note 8: It is obvious from the recurrence 37 together with the initial conditions that all $S1(k;n,m)$ are integers for $k \in \mathbf{Z}$.

Definition 4: $s1(k;n,m)$. The *associated $k-$Stirling numbers of the first kind*, $s1(k;n,m)$, are defined for

[4]This linear independence can be proved by applying the differentiation operators $\frac{1}{p!}\,\mathcal{O}_x(k;p)$ for fixed $k \in \mathbf{Z}$ and $p = 1,...,n$ to the monomials x^q, for $q = 1,..,n$. The linear independence is then inferred from the non-singularity of the $n \times n$ matrix $A_{q,p}(k) \;=\; \frac{1}{p!}\,\prod_{j=0}^{p-1}(q + j(k-1))$. In fact, $Det\, \mathbf{A}(k) = +1$ for each $k \in \mathbf{Z}$ and $n \in \mathbf{N}$.

$k \in \mathbf{Z} \setminus \{1\}$ by eq. 38.

Lemma 15: The numbers $s1(k;n,m)$ satisfy the recurrence given in eq. 39.

Proof: Rewrite the recurrence relation eq. 37 for $S1(k;n,m)$ with $k \neq 1$. The lower triangularity of the matrix $\mathbf{s1}(k)$ is inherited from $\mathbf{S1}(k)$. □

Note 9: For $k = 1$ eq. 39 gives the unit matrix $\mathbf{s1}(1) = \mathbf{1}$. This will be used as the definition of $\mathbf{s1}(1)$.
Lemma 16: Nonnegativity of $\mathbf{s1}(k)$. The entries of the lower triangular matrix $\mathbf{s1}(k)$ are nonnegative for each k.

Proof: If $k-1 \geq 0$ this follows from eq. 39. For $1-k \in \mathbf{N}$ this follows from the fact that $s1(k;n-1,m) = 0$ if $n-1 > (1-k)\,m$, *i.e.* if the coefficient of the first term in the recurrence eq. 39 is negative. This will be shown by induction on m. For $m = 1$ the assertion is true because only the first term in the recurrence is present, and since $s1(k,2-k,1) = 0$, due to the vanishing coefficient of the first term in its recursion, the recurrence shows that $s1(k;n-1,1)$ vanishes for $n-1 = 2-k, 3-k, ...$ (if $n-1 = 2-k$ the multiplier in the first recursion term vanishes). Assuming the assertion holds for given $m \geq 1$, *i.e.* $s1(k;n-1,m) = 0$ for $n-1 > (1-k)\,m$, leads to a vanishing second term in the $s1(k;n-1,m+1)$ recurrence for all $n-1 > (1-k)\,m + 1$. Therefore, $s1(k;(1-k)\,(m+1)+1,m+1)$ will be zero because the coefficient of the first term of this recurrence vanishes and the second term is absent since $(1-k)\,(m+1) > (1-k)\,m$. Then $s1(k;n-1,m+1)$ vanishes recursively for all $n-1 \geq (1-k)\,(m+1)+1$. □

Lemma 17: The o.g.f. for the m-th column of $\mathbf{s1}(k)$ (see eqs. 40, 41 and 42). $\mathbf{s1}(k)$ is a Bell matrix (see Note 7 for this name), *i.e.* the o.g.f. for the sequence $\{s1(k;n,m)\}_{n=1}^{\infty}$ is given by $g1(k;m;y) = (g1(k;1;y))^m$ and

$$g1(k;y) := g1(k;1;y) = \frac{-1 + (1-(k-1)\,y)^{-(k-1)}}{(k-1)^2} \quad \text{for} \quad k \in \mathbf{Z} \setminus \{1\}\,. \tag{72}$$

Since we have set $\mathbf{s1}(1) = \mathbf{1}$ we take $g1(1;y) = y$.

Proof: From the recurrence relation eq. 39 we find, for $k \in \mathbf{Z}$, the first-order linear differential-difference equation

$$[1-(k-1)\,y]\,g1'(k;m;y) - m\,(k-1)^2\,g1(k;m;y) - m\,g1(k;m-1;y) = 0\ , \tag{73}$$

$$g1(k;m;0) = 0\ ,\ m \in \mathbf{N};\quad g1'(k;m;y)|_{y=0} = s1(k;1,1)\,\delta_{m,1} = \delta_{m,1}. \tag{74}$$

The prime denotes differentiation with respect to y. The $y = 0$ conditions follow from the definition of $g1(k;m;y)$ in eq. 40. Eq. 73 is solved using $g1(k;m;y) = (g1(k;1;y))^m$, which results in a standard linear inhomogeneous differential equation for $g1(k;y) := g1(k;1;y)$, namely

$$[1-(k-1)\,y]\,g1'(k;y) - (k-1)^2\,g1(k;y) - 1 = 0\,, \tag{75}$$

with the initial condition $g1(k;0) = 0$. The solution is given by equation eq. 72 (cf. eq. 41, 42). □

Note 10: Generalized *EIS* A001792 sequences. Analogous to the generalized Catalan numbers generated by $c2(l;y)$ of eq. 23 (see Note 4), we can use $c1(l;y)$ defined in eq. 42 as the o.g.f. for sequences $\{c1_n^{(l)}\}_{n=0}^{\infty}$. We find that $c1(1;y) = 1/(1-y)$ generates *EIS* A000012 (powers of 1), $c1(2;y)$ is the o.g.f. for the sequence A001792(n). The *EIS* A-numbers for the sequences for $l = k-1$ are found in the second column of Table 3 for $l = 1, ..., 5$ and $l = -1, ..., -6$. See also *EIS* A053113. In order to have $g1(1;y) = y$ we set $c1(0;y) \equiv 1$ (see eq. 41). An explicit expression for $c1_n^{(l)}$ with $l \in \mathbf{N}$ is given in eq. 43. Also $c1_n^{(0)} = \delta_{n,0}$, and $c1(-l;x)$ is a polynomial in x for $l \in \mathbf{N}$. For example, $c1(-3;x) = 1 + 3\,x + 3\,x^2$. The triangle of coefficients in these polynomials can be found as *EIS* A049323 (increasing powers of x), or A033842 (decreasing powers of x). The explicit form for these coefficients is given in eq. 44.

Lemma 18: The entries of the matrix $\mathbf{s1}(k)$ are integers for all $k \in \mathbf{Z}$.

Proof: The first column of $\mathbf{s1}(k)$ consists of integers since $c1(k-1;y)$ generates the integers $c1_n^{(k-1)}$ given explicitly in eqs. 43 and 44, and $g1(k;y)$ is given by eq. 41 (see Lemma 17). The case $k = 1$ is trivial.

Since $\mathbf{s1}(k)$ is an ordinary convolution triangle (or Bell matrix) it is sufficient to prove that the first column consists of integers. □

Lemma 19: The entries of the matrix $\mathbf{s2}(k)$ are integers for all $k \in \mathbf{Z}$.

Proof: Once this has been established, all entries of $s2(k;n,m)$ are nonnegative integers by Lemma 3. For the proof we first substitute eqs. 18 and 38 into eq. 69. Define, for $k \in \mathbf{Z}$, the signed matrix $\mathbf{s2s}(k)$ by $s2s(k;n,m) := (-1)^{n-m}\, s2(k;n,m)$. Then eq. 69 implies

$$\mathbf{s2s}(k) \cdot \mathbf{s1}(\mathbf{k}) \;=\; \mathbf{1}\;. \tag{76}$$

Using the fact that the $s1(k;n,m)$ are integers from the previous lemma (from Lemma 16 they are even known to be nonnegative) this equation allows us to carry out the proof recursively. We omit the details. □

Note 11: Using Lemmas 16 and 19, eqs. 21 and 22 show that $c2(l;y) = \sum_{n=0}^{\infty} c2_n^{(l)}\, y^n$ defined in eq. 23 generates positive integers for all $l \in \mathbf{Z} \setminus \{0\}$. Their explicit form is given by

$$c2_n^{(l)} \;=\; l^n \prod_{j=1}^{n} (j\,l-1)/(n+1)!\;. \tag{77}$$

By definition $c2(0;y) := 1$.

Lemma 20: The e.g.f. for the $m-th$ column sequence of the unsigned $k-$Stirling triangle of the first kind, $\mathbf{S1p}(k)$, defined in eq. 36 for $k \in \mathbf{N}$, is $G1p(k;m;x) = \frac{1}{m!}\,(G1p(k;1;x))^m$, $m \in \mathbf{N}$, with $G1p(k;1;x) \equiv G1p(k;x) = (k-1)\,g1(k;\frac{x}{k-1})$ for $k = 2,3,...$ and $G1p(1;1;x) \equiv G1p(1;x) = -ln(1-x)$.

Proof: For $k \geq 2$ substitute $S1p(k;n,m)$ from eqs. 36 and 38 into the definition of $G1p(k;m;x)$ given in eq. 46. In this way the o.g.f. $g1(k;m;y)$ appears in the desired form. The result for the ordinary unsigned Stirling numbers ($k=1$) is well-known [1]. □

Note 12: Explicit form for $G1p(k;m;x)$, $k>1$: eq. 48 and Lemma 20. Equation 48 follows from the o.g.f. $g1(k;m;y)$ in eqs. 40 and 72. This shows that $G1p(k;1;x) = -\overline{G2(k;-x)}$, the negative compositional inverse of $G2(k;-x)$ of eq. 24. Inverse Jabotinsky matrices like $\mathbf{S2}$ and $\mathbf{S1}$ (*cf.* eqs. 69 and 71) have first column e.g.f.'s which are inverse to each other in the compositional sense [4].

Lemma 21: Row polynomials for $\mathbf{S1}(k)$. For $k \in \mathbf{Z}$ the e.g.f. of the row polynomials $S1_n(k;x) := \sum_{m=1}^{n} S1(k;n,m)\, x^m$, $n \in \mathbf{N}$, and $S1_0(k;x) := 1$ is

$$\mathcal{G}1(k;z,x) := \sum_{n=0}^{\infty} S1_n(k;x)\, z^n/n! \;=\; e^{x\,G1(k;z)}\;, \tag{78}$$

where $G1(k;z) = (-1+(1+z)^{1-k})/(1-k)$ for $k \neq 1$, and $G1(1;z) = ln(1+z)$ are the e.g.f.s for the first ($m=1$) column sequences of the triangular matrices $\mathbf{S1}(k)$.

Proof: Analogous to that of Lemma 9.

Note 13: $S1(k;n,m) = \left[\frac{z^n}{n!}\right]\,[x^m]\,e^{x\,G1(k;z)}$ (cf. Note 7).

Proposition 5: Exponential convolution property of the $S1_n(k;x)$ polynomials. The row polynomials $S1_n(k;x)$ defined in Lemma 21 for $n \in \mathbf{N}_0$, satisfy for each $k \in \mathbf{Z}$ the exponential (or binomial) convolution property shown in eq. 26 with $S2$ replaced everywhere by $S1$.

Proof: For fixed k, compare the coefficients of $z^n/n!$ on both sides of the identity $\mathcal{G}1(k;z,x+y) = \mathcal{G}1(k;z,x)\,\mathcal{G}1(k;z,y)$. □

Note 14: In the notation of the umbral calculus (*cf.* [7]) the polynomials $S1_n(k;x)$ are called associated polynomial (or Sheffer) sequences for $(1, \overline{G1(k;t)} = G2(k;t))$. For $k \neq 1$ $G2(k;t)$ is given in eq. 24. Also

$\overline{G1(1;t)} = G2(1;t) = exp(t) - 1$.

Proposition 6: O.g.f. for row sums of $\mathbf{s1}(k)$ triangles. For $k \in \mathbf{Z} \setminus \{1\}$ the o.g.f. of the sequence of row sums of the lower triangular matrix $\mathbf{s1}(k)$ is given by eq. 52.

Proof: Lemma 11 and the $g1(k;x)$ result in Lemma 17. □

Proposition 7: E.g.f. of the sequence of row sums of $\mathbf{S1p}(k)$ and $\mathbf{S1}(-|k|)$ triangles. For $k \in \mathbf{N_0}$ the e.g.f. of the sequence of row sums of the nonnegative lower triangular matrix $\mathbf{S1p}(k)$, resp. $\mathbf{S1}(-|k|)$, defined in eq. 36, resp. eq. 37, is given by eq. 55, resp. eq. 56.

Proof: Lemma 12 and $G1p(k;x)$, resp. $G1(-|k|;x)$, from Lemma 20, *i.e.* eq. 48, resp. eq. 49. □

Note 15: Row-sums of signed $\mathbf{S1}(k)$, $k \in \mathbf{N}$, resp. $\mathbf{S1s}(-|k|)$ triangles. Here Lemma 12 applies with the e.g.f.s $G1(k;x)$, resp. $G1s(-|k|;x)$, given in the first line after eq. 78, resp. in the paragraph after eq. 49.

Acknowledgements

The author would like to thank Stefan Theisen for a conversation at a very early stage of this work (Note 6, case $k = 1$). Thanks go also to Norbert Dragon who pointed out his web-pages (ref. [2]). This work has its origin in an exercise in the author's 1998/1999 lectures on conformal field theory (*Konforme Feldtheorie*, Blatt 1, Aufgabe 2, available as a ps.gz file under http://www-itp.physik.uni-karlsruhe.de/~wl/Uebungen.html).

Abstract: A set-theoretic structure, the *magic carpet*, is defined and some of its combinatorial properties explored. The magic carpet is a generalization and abstraction of labeled diagrams such as magic squares and magic graphs, in which certain configurations of points on the diagram add to the same value. Some basic definitions and theorems are presented as well as computer-generated enumerations of small non-isomorphic magic carpets of various kinds.

Introduction

In its most general form, a **magic carpet** is a collection of k different subsets of a set S of positive integers, where the integers in each subset sum to the same **magic constant** m. In this paper we always take $S = \{1, 2, 3, \ldots n\}$, and refer to a magic carpet on this set as an **(n, k)-carpet**.

A (9,8)-carpet is shown in Figure 1, with each element of S depicted as a point (labeled with the element it represents) and each subset of S as a line connecting the points in that subset.

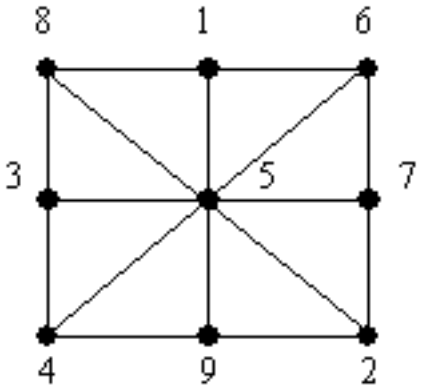

Figure 1. A (9,8) magic carpet

This is just an ordinary 3x3 magic square, with each row, column, and diagonal having the same magic sum. Indeed, the motivation for this study is to generalize the notion of a magic square to an arbitrary structure on the set {1...*n*}, and to count and classify all non-isomorphic carpets on *n* points. By doing so, all possible "diagrams" of this type, in which points are labeled by {1...*n*} and whose lines or circles or other geometric elements pass through points with the same sum, can be generated. By omitting labels, such a diagram turns into a puzzle whose object is to determine the magic numbering. For example, the seven intersections in Figure 2 can be numbered with {1...7} such that the circle and each of the two ellipses sum to the same value. Can you verify that this is a (7,3) magic carpet by finding such a numbering? (The answer is given later, in Figure 4.)

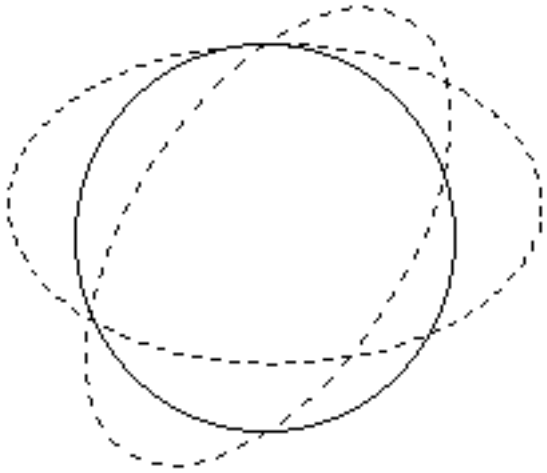

Figure 2. A 7-point diagram that can be magically numbered.

A magic carpet is a generalization of other structures which have appeared in the literature, such as magic circles [5], magic stars [3], and magic graphs [2].

Definitions

Denote the subsets of S by S_1, ..., S_k. Let element i in S be included ("covered") c_i times in the union of all the S_i. The **thickness** of a carpet is $t = min\{c_i\}$ and its **height** is $h = max\{c_i\}$. Since $t <= h$, there are two cases: a **smooth** carpet with $t = h$, or a **bumpy** one with $t < h$. Because of the analogy with magic

squares, **holey carpets** with $t = 0$ are not very interesting, since we would like each element of S to be covered at least once (or, equivalently, for every number from 1 to n to be used in labeling the figure). In fact, a magic square has $t = 2$, so we are also less interested in the **thin carpets** with $t = 1$. Instead, we prefer to concentrate on **plush carpets** with $t >= 2$.

Let the subset S_i have e_i elements. Define the **weave** of a carpet to be $w = min\{e_i\}$. Again motivated by magic squares, we note that **loose carpets** with $w = 1$ are not as interesting as **tight** ones with $w >= 2$. If all the e_i are equal (i.e., all subsets are the same size) then the carpet is **balanced**.

Example: an r x r magic square, $r >= 3$ odd (with rows, columns, and two diagonals having the same magic sum), is a magic carpet with $n = r^2$, $k = 2r + 2$, $t = 2$, $h = 4$ and $w = r$. It is balanced but not smooth, since $t < h$. Its non-smoothness is due to the diagonals being covered three times and the central square four times, while the rest are only covered twice. If the diagonals are omitted (so that we have a so-called semi-magic square) then it becomes smooth. In either case, it is plush (since $t = 2$) as well as tight (since $w >= 2$).

Define a **basic** magic carpet to be one that is both plush and tight. Two magic carpets are **isomorphic** if they are equivalent under some permutation of the elements of S. (Of course, equality of the collection of subsets is made without regard to order of the subsets.) The motivation for this definition is that two carpets which are equivalent under a permutation of S correspond to two different magic numberings of the same "figure"; i.e., we seek magic carpets with the same basic structure. In other words, we wish to enumerate all essentially different magic-numbering puzzles (blank diagrams), not all distinct solutions (labeled diagrams).

Results

The primary combinatorial problem is to determine $B(n)$ or $B(n,k)$, the number of non-isomorphic basic magic carpets with given parameters. We also denote by $M(n,k,t,h)$ the number of magic carpets (basic or not) of type (n,k,t,h).

Theorem 1: $B(n) = 0$ for $n < 5$, $B(5) = 1$, $B(n) >= 1$ for $n >= 6$.

Proof: The values for $n <= 5$ are easily obtained by direct enumeration. For $n > 5$, observe that any (n, k) magic carpet can be extended to an $(n+1, k)$ carpet by taking each S_i, adding 1 to each of its elements, then appending the element "1".

The *unique smallest basic magic carpet*, with $(n,k,t,h) = (5,3,2,2)$, can be drawn as shown in Figure 3. It is smooth but not balanced.

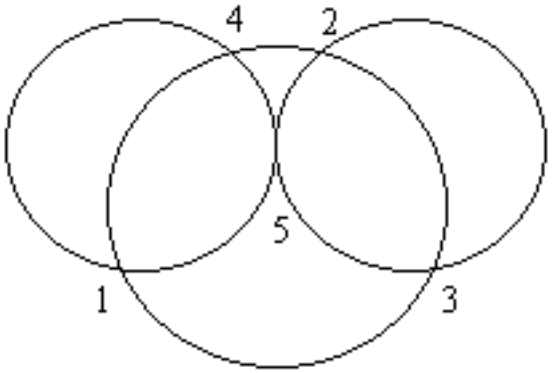

Figure 3. The unique (5,3) basic magic carpet.

Theorem 2: $M(n,k,t,h) = M(n,k,n-h,n-t)$.

Proof: From each (n,k,t,h) carpet, form another one by taking the complements of the S_i.

Two carpets which are related by complementation of the subsets are called **duals**. Note that if C' is the dual of carpet C that has magic constant m, then C' has magic constant $T_n - m$, where $T_n = n(n+1)/2$, the nth triangular number.

We now ask a fundamental question: for a given n, which values of k admit a basic magic carpet? From the definitions it is clear that $2 <= k <= 2^n - n - 1$ (the latter being the number of subsets with at least two elements); however, the actual range of k is considerably smaller than this.

Theorem 3: There is a basic (n,k) magic carpet if and only if $n >= 5$ and $3 <= k <= q$, where q is the largest coefficient in the polynomial

$$P_{(n)} = \prod_{i=1}^{n} (1+x^i)$$

Proof: See Theorem 1 for the proof that $n >= 5$ is necessary and sufficient. Obviously k cannot be 2, because two distinct subsets of $\{1...n\}$ cannot cover all elements twice. Thus $k >= 3$ is necessary. That $k <= q$ is necessary is trivial, since the coefficient of x^j in $P(n)$ is the number of distinct subsets of $\{1...n\}$ whose elements sum to j, and q is by definition the maximum coefficient.

We now show that $3 <= k <= q$ is sufficient.

Let $d_j(n)$ be the coefficient of x^j in the polynomial $P(n)$ given above. Note that the sequence $d_j(n)$ is

symmetric:

$$d_j(n) = d_{T_n - j}(n). \qquad (*)$$

Let

$$q(n) = \max_j d_j(n)$$

which equals the maximal number of subsets of {1,...*n*} that have the same sum. Finally, define *m*(*n*) to be the largest integer such that $d_{m(n)}(n) = q(n)$.

Lemma 1: $T_n/2 <= m(n) <= T_n - 5$.

Proof: The first inequality follows from (*). For $n >= 4$, $d_0, d_1, d_2, d_3, d_4, d_5 = 1,1,1,2,2,3$. Since $d_5(n) > d_j(n)$ for $0 <= j <= 4$, (*) gives $d_{T_n - 5}(n) > d_{T_n - j}(n)$ for $0 <= j <= 4$, which means that *m*(*n*) is at most $T_n - 5$.

Lemma 2: Let $n >= 6$ and $1 <= j <= n$. There are at least two subsets of {1...*n*} that add to *m*(*n*) and contain *j*.

Proof: The number of subsets of {1...*n*} that add to *m*(*n*) and contain *j* is the coefficient of $x^{m(n)-j}$ in the polynomial

$$P(n, j) = (1+x^j) \prod_{i=1}^{n} (1+x^i)$$

We prove by induction on *n* that this coefficient is always at least 2.

By Lemma 1, it is necessary to show that the coefficients of x^r in *P*(*n*,*j*) are at least 2 for $T_n/2 <= r-j <= T_n - 5$, or $T_n/2 - j <= r <= T_n - 5 - j$. If a given *P*(*n*,*j*) satisfies this we say that *P*(*n*,*j*) has *property P*.

The lemma is true for n=6 since the coefficients of $P(n,j)$ are

```
j=1: 10111222232222211101
j=2: 11012222233222221011
j=3: 11111233223332211111
j=4: 11121232332321212111
j=5: 11122233233222122111
j=6: 11122333333221122111
```

and each of these (as indicated by the boldface numbers) has property P.

Now consider two cases:

Case I: $j <= 6$. We have

$$P(n, j) = P(6, j) \prod_{i=7}^{n} (1+x^i)$$

We know $P(6, j)$ has property P (see table above), and multiplying by each factor i in the product is equivalent to shifting the vector of coefficients to the right by i places and adding to the original. This preserves property P.

Case II: $j > 6$. In this case we start with

$$\prod_{i=1}^{6} (1+x^i)$$

which has coefficients 11122344455**5444**322111 and satisfies property P. Again, multiplying this by the remaining $(1+x^i)$ will preserve property P.

Lemma 3: $d_{m(n-1)}(n) = d_{m(n-1)}(n-1) + d_{m(n-1)-n}(n-1)$.

Proof: Since

$$\prod_{}^{n} (1+x^i) = (1+x^n) \prod_{}^{n-1} (1+x^i)$$

i=1 i=1

it follows from the definition of $d_j(n)$ that $d_j(n) = d_j(n\text{-}1) + d_{j-n}(n\text{-}1)$. The lemma follows by setting $j = m(n\text{-}1)$.

Lemma 4: For $n >= 10$, $q(n\text{-}1) > 2n$.

Proof: Consider the equation of Lemma 3. The left-hand side is no larger than $q(n)$. The first term on the right-hand side is $q(n\text{-}1)$. The second term is at least 2, because Lemma 1 says that $m(n\text{-}1)\text{-}n >= T_{n\text{-}1}/2 - n$, the right-hand side of which is at least 3 (if $n >= 7$), and $d_j(n)$ is at least 2 if j is at least 3. Therefore, $q(n) >= q(n\text{-}1)+2$.

Now note that the values of $q(n)$, starting with n=5, are:

3, 5, 8, 14, 23, 40, 70, 124, 221, 397, ...

which is sequence A25591 in [6]. Since $q(10\text{-}1) = 23 > 2\ 10$, the lemma is true for n=10. Using $q(n) >= q(n\text{-}1)+2$ and induction on n completes the proof.

We can now prove Theorem 3 by induction. First, it is true for $n < 10$ by direct construction by computer. We can construct (n,k) basic magic carpets for $3 <= k <= q(n\text{-}1)$ by taking an $(n\text{-}1,k)$ carpet and appending n to each subset. By Lemma 4, this gives carpets for $3 <= k <= 2n$.

Next, we construct an (n,k) basic magic carpet with $k = 2n$ and magic constant $m(n)$. For each j, $1 <= j <= n$, we find two subsets which add to $m(n)$ and contain j, which is possible by Lemma 2. We can add any number of additional subsets and still have a basic magic carpet, thus producing basic (n,k) carpets for $2n <= k <= q(n)$, and completing the proof.

Numerical Results

Table 1 shows all values of $B(n,k)$ up to n=8, determined by computer calculation. The initial values of $B(n)$, starting with n=5, are 1, 10, 271, 36995, ... (sequence A55055).

	k=3	4	5	6	7	8	9	10	11	12	13	14	**Total**
n=5	1												1
6	2	4	4										10
7	2	23	98	105	38	5							271

8	6	112	1300	5570	10090	9907	6240	2739	840	170	20	1	36995

Table 1. The values of $B(n,k)$ for small indices.

Table 2 lists all the basic carpets for small values of n and k. For each carpet, the magic sum and the elements in each subset are listed (in a compact format: 1234 means {1,2,3,4}).

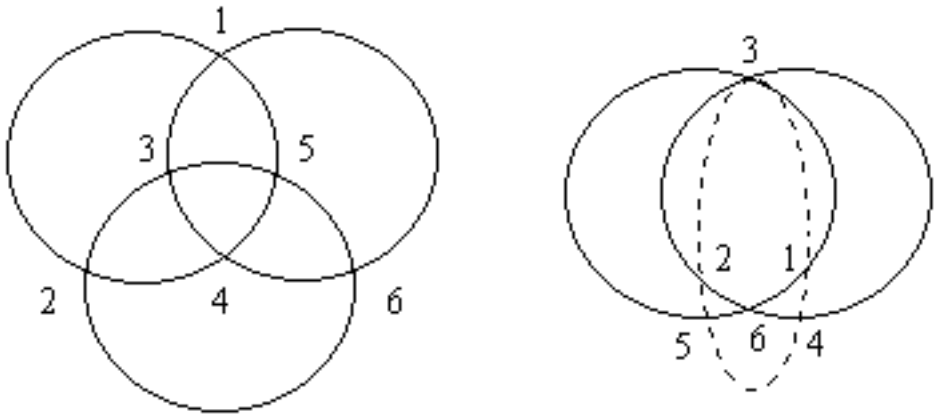
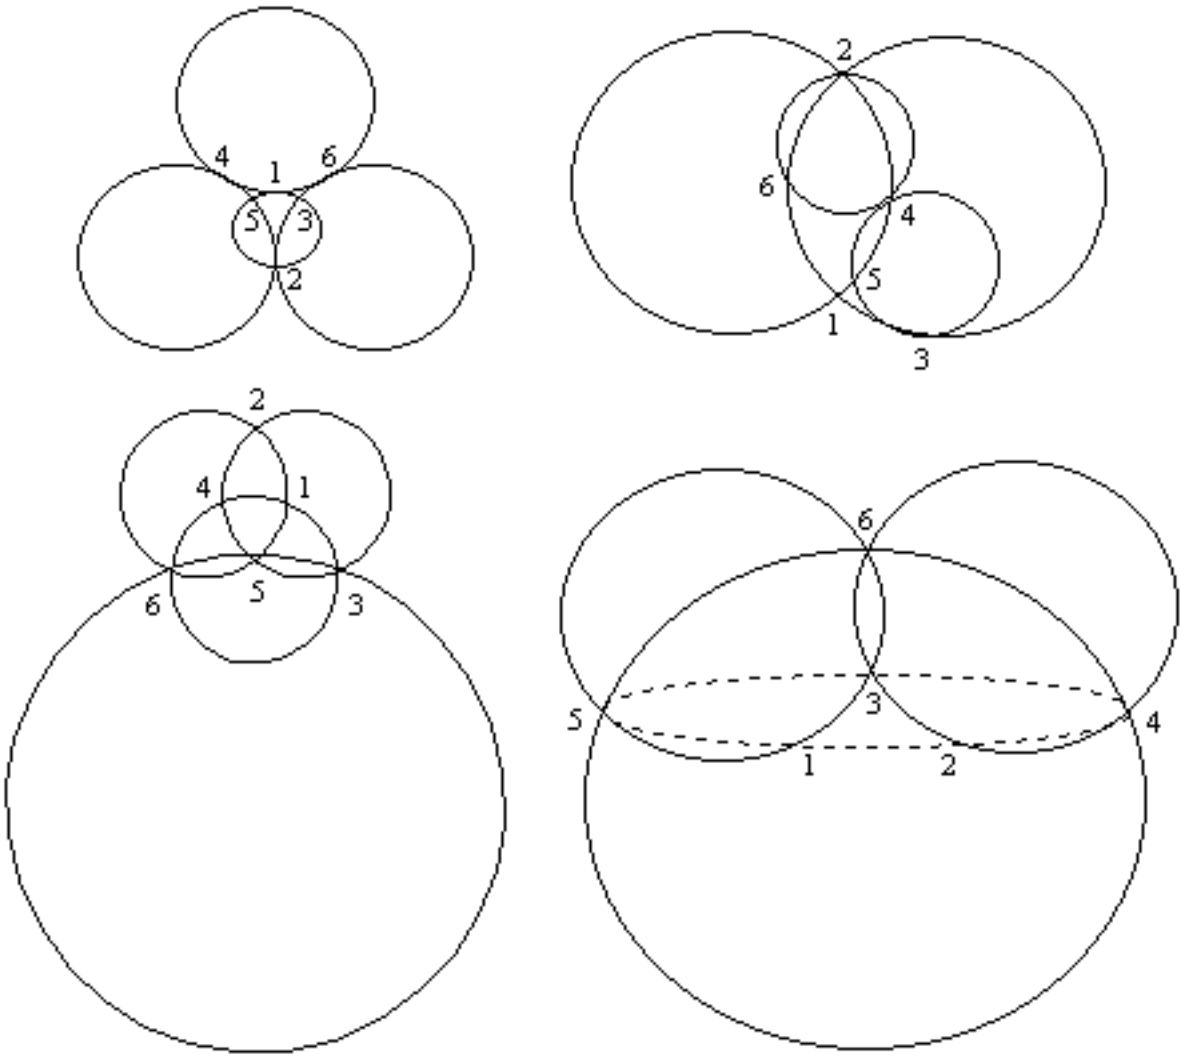
Table 2. The non-isomorphic basic magic carpets for small (*n,k*).

The (5,3) carpet was shown graphically in Figure 3. The (6,3), (6,4), (6,5), and (7,3) carpets are depicted in Figure 4 (in the same order they are listed in Table 2).

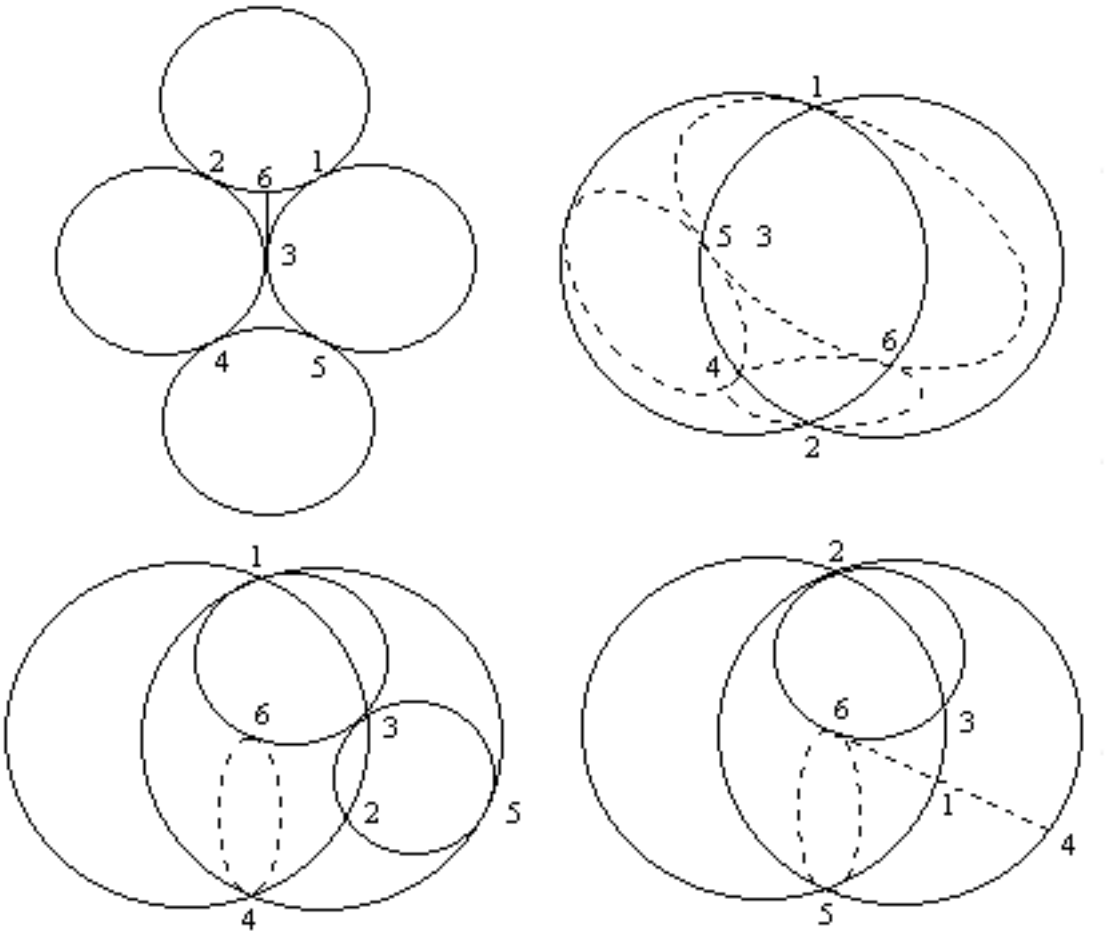
(6,3):



(6,4)



(6,5)



(7,3)

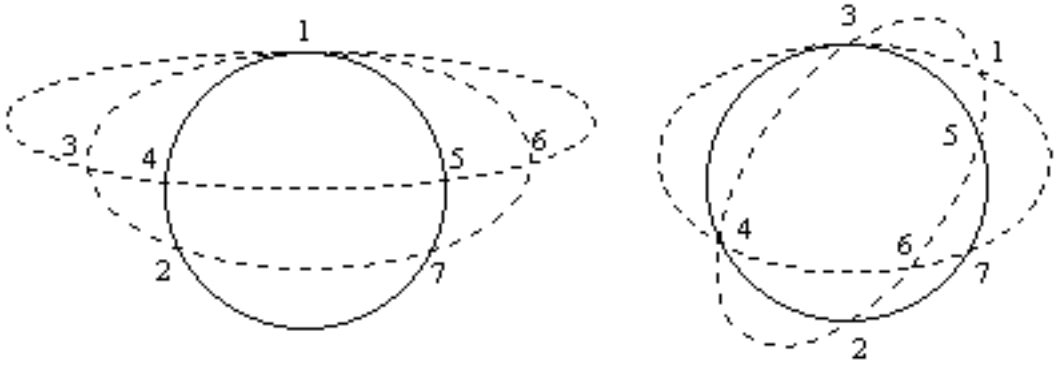


Figure 4. The distinct basic magic carpets for n=6 and (n,k) = (7,3).

These figures show just one way of diagramming each magic carpet (in this case, primarily using circles and ellipses). The question of how best to visualize a carpet is primarily an aesthetic one.

The first (6,3) carpet in Figure 4 (one of the "magic circle" figures shown in [5]) is the smallest one that is both smooth and balanced, and also the smallest one with a high degree of symmetry (six-fold).

Since many well-known magic structures (such as magic squares and stars) are either smooth and/or balanced, it is of interest to enumerate just the smooth or balanced basic carpets. Table 3 shows the number of smooth basic carpets for all (n,k) up to n=9. The last column is sequence A55056.

	k=3	4	5	6	7	8	9	10	11	12	13	14	15	**Total**
n=5	1													1
6	1													1
7		2		2	2	1								7
8	2	4		9		11	8	12		8		1		55
9	3		19	10			548	156		2			568	1306

Table 3. The number of smooth basic (*n*,*k*) magic carpets up to *n*=9.

In this table, empty cells indicate that there are no smooth carpets for that (*n*,*k*). (There are also none for *n*=9 and *k* > 15). Some of these missing (*n*,*k*) values are explained by:

Theorem 4: (*n*,*k*) basic balanced carpets can exist only if there exists a 2 <= *t* <= *k* with

$$t\,T_n = 0 \pmod{k}.$$

Proof: Since each element of *S* appears exactly *t* times in the union of all the subsets, the sum of all elements of the subsets is $t\,T_n$. This means that the magic constant is $t\,T_n/k$, which must be an integer, and so the theorem follows.

For example, for *n*=9 smooth carpets cannot exist, by Theorem 4, for *k* = 13, 14, 16, 17, 19, 22, and 23. However, this theorem does not predict *all* inadmissable *k* values - Table 3 also gives zeros for *k* = 4, 7, 8, 11, 18, 20, and 21. A complete characterization of which (*n*,*k*) pairs permit smooth basic carpets remains an open problem.

The largest *k* value which admits a smooth carpet (for *n*=5, 6...) is 3, 3, 8, 14, 15... (sequence A55057).

Table 4 gives the number of *balanced* basic carpets for all (*n*,*k*) up to *n*=9 (last column is sequence A55605).

	k=3	4	5	6	7	8	9	10	11	12	**Total**
6	1										1
7	1	1	2								1
8	1	5	12	15	4	1					38
9	2	10	73	343	699	688	367	118	22	2	2324

Table 4. The number of balanced basic (*n,k*) magic carpets up to *n*=9.

The largest *k* value which admits a smooth carpet (for *n*=6, 7,...) is 3, 5, 8, 12, 20, 32, 58, 94, 169, 289... (sequence A55606).

All balanced carpets up to *n*=8 are listed in Table 5.

(*n*, *k*)	Sum	Subsets

Abstract

A bijection between split graphs and minimal covers of a set by subsets is presented. As the enumeration problem for such minimal covers has been solved, this implies that split graphs can also be enumerated.

1 Motivation

A *split graph* is a chordal graph with a chordal complement. It is straightforward to recognize split graphs, and therefore to compute the numbers of split graphs on a small number of vertices, as shown in Table 1. Whenever such a table is given, it is to be understood that they contain numbers of pairwise non-isomorphic objects, rather than 'labeled' objects. The numbers in Table 1 form sequence A48194 in [5], which is an online database of interesting sequences of integers (see also [4]). One of the aims of this database is to permit researchers who encounter a sequence to determine whether it has occurred before, and in what context, thereby exposing possibly unexplored connections.

A k-cover of an n-set N is a collection of k subsets of N whose union is N. A k-cover is *minimal* if no sub-collection also covers N. Clarke [1] gives an expression for the number of minimal k-covers of an n-set (where again it is to be understood that the numbers refer to the number of pairwise non-isomorphic objects). Using this formula, Michael Somos (private communication) computed the total number of minimal covers of an n-set and using [5] observed that for $n \leq 11$ (the limit of the sequence known at that time), this number was equal to the number of split graphs on n vertices.

The current paper shows that this is no coincidence by proving the following result:

1.1 THEOREM. *There is a one-one correspondence between the split graphs on n vertices and the minimal covers of a set of size n.*

Table 1: Split graphs on small numbers of vertices

2 Background

In this paper, a graph means an undirected graph without multiple edges or loops. For basic graph theory terminology and background, the books of Diestel [2] and West [6] are recommended.

A graph is *chordal* (or *triangulated*) if it has no cycle of length 4 or greater as an induced subgraph. Chordal graphs form an important class of graphs, and have been extensively studied, particularly with respect to determining the complexity of a wide range of problems known to be NP-hard for general graphs. A *split graph* is a chordal graph with a chordal complement; this terminology arises because a graph X is a split graph if and only if there is a partition $V(X) = I \cup C$ where I is an independent set and C a clique (see Foldes & Hammer [3]). Thus X can be 'split' into a clique and an independent set—a split $V(X) = I \cup C$ will be called *special* if every vertex in C is adjacent to at least one vertex in I. Every split graph has a special split, because if there is a vertex in C not adjacent to any element of I, it can be moved to I.

In general a k-cover of an n-set may include both empty sets and multiple occurrences of a subset. The k-covers S_1 of N_1 and S_2 of N_2 are isomorphic if there is a bijection $\phi : N_1 \mapsto N_2$ such that $\phi(S_1) = S_2$. Clarke [1] considers several enumeration problems for k-covers. He encompasses the situations where the cover is ordered or unordered, minimal or not-necessarily minimal and counting is done both by total numbers or numbers of isomorphism classes. However we will only need to use the number of isomorphism classes of minimal covers—what Clarke terms 'minimal disordered unlabeled covers'. Figure 1 shows a minimal 4-cover of a 9-set—in a manner analogous to drawing a graph it represents an isomorphism class, rather than a 'labeled' cover.

Given a cover $S = \{S_1, \ldots, S_k\}$, we define an element $a \in N$ to be *loyal* if it lies in only one of the subsets S_i. If S is a minimal cover, then every subset S_i contains a loyal element.

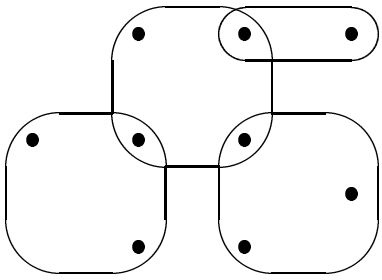

Figure 1: A minimal 4-cover of a 9-set

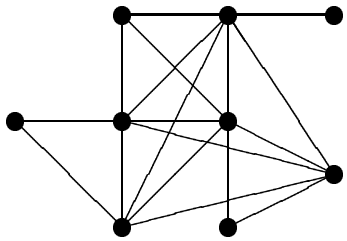

Figure 2: A split graph

3 Bijection

In this section we present a bijection between split graphs on n vertices and minimal covers of a set of size n.

Given a minimal cover $S = \{S_1, \ldots, S_k\}$ of a set N, form a graph $X = X(S)$ with vertex set N as follows. Let $I \subseteq V(X)$ be a set obtained by choosing (arbitrarily) one loyal element from each set S_i. Let X be the graph whose edge set is the union of a clique on each of the sets S_i and a clique on $V(X)\backslash I$. It is straightforward to verify that a different choice for the subset I does not alter the isomorphism class of X. Figure 2 shows the graph that arises from the cover of Figure 1.

3.2 Lemma. *If S is a minimal cover, then the graph $X = X(S)$ defined above is a split graph.*

Proof. As a loyal element belongs to one subset S_i, it follows that I is an independent set of X. By definition $V(X)\backslash I$ is a clique, and therefore X is a split graph. ■

Now, given a split graph X, form a cover $S = S(X)$ of $V(X)$ as follows. Let $\mathcal{M}$ be the set of maximal cliques of X. Define a maximal clique $M \in \mathcal{M}$ to be *essential* if there is a vertex $v \in V(X)$ that lies only in M. Then take S to be the set of essential maximal cliques of X.

3.3 Lemma. *If X is a split graph, then the cover $S = S(X)$ defined above is a minimal cover.*

Proof. Let $V(X) = I \cup C$ be a special split of X. Every vertex in I lies in a unique maximal clique, consisting of itself and its neighbors. Each of these maximal cliques is essential, and as every vertex in C is in one of these cliques, they form a cover of $V(X)$. There are no other essential maximal cliques and none of this collection can be omitted while still covering the vertices in I,

and hence S is a minimal cover. ∎

3.4 THEOREM. *There is a one-one correspondence between split graphs on n vertices and minimal covers of an n-set.*

PROOF. If X is a split graph with special split $V(X) = I \cup C$, then in the cover $S(X)$, the vertices of I form a collection of loyal elements one from each subset in $S(X)$. It follows that $X = X(S(X))$ and therefore the two maps $X \mapsto S(X)$ and $S \mapsto X(S)$ are inverses. ∎

4 Enumeration

We can now provide a formula for counting split graphs on n vertices, using Clarke's formulas. The first step is to obtain an expression for the number of isomorphism classes of all (not necessarily minimal) k-covers of an n-set. This involves a double summation over all partitions of n and k. Denote the set of all partitions of n by $\mathcal{P}_n$. A partition $\alpha \in \mathcal{P}_n$ is given by a sequence $[\alpha_1, \alpha_2, \ldots, \alpha_m]$ of integers summing to n. If α is such a partition and μ_i is the number of parts of size i, then let

$$\binom{n}{\alpha} = \frac{n!}{\prod_i \mu_i! i^{\mu_i}}.$$

Clarke [1] shows that the number of isomorphism classes of k-covers of an n-set is given by

$$t(n,k) = \frac{1}{n!k!} \sum_{\alpha \in \mathcal{P}_n, \beta \in \mathcal{P}_k} \binom{n}{\alpha} \binom{k}{\beta} \prod_i \left(\left(\prod_j 2^{(\alpha_i, \beta_j)} \right) - 1 \right),$$

and the number of isomorphism classes of minimal k-covers of an n-set is

$$m(n,k) = t(n-k,k).$$

Therefore, if $s(n)$ is the number of split graphs on n vertices,

$$s(n) = \sum_{k=1}^{n} m(n,k) = \sum_{k=1}^{n} t(n-k,k).$$

Table 2 gives the values of $s(n)$ for $n \leq 20$, as computed with Maple. (Note that the table of values for $t(n,k)$ given in Clarke [1] gives slightly incorrect values for $t(6,8)$, $t(7,7)$ and $t(7,8)$.)

Acknowledgements

I would like to thank Michael Somos for letting me know of his observation, and Neil Sloane for making it possible.

This research was supported in part by funds from an NSERC operating grant.

Abstract

Numbers of the form $(b^n + 1)/(b + 1)$ are tested for primality. A table of primes and probable primes is presented for b up to 200 and large values of n.

1999 *Mathematics Subject Classification*: Primary 11A41
Keywords: prime numbers, generalized repunits

1. Introduction

A truly prodigious amount of computation has been devoted to investigating numbers of the form $b^n \pm 1$. The Cunningham project, to factor these numbers for b from 2 to 12, is perhaps the longest running computer project of all time [4]. The range of b has been extended to 100 and even further in special cases [1][2] . The Mersenne numbers, $2^n - 1$ have been studied extensively for hundreds of years and the largest known prime is almost always a Mersenne prime. In [6], generalized repunit primes of the form $(b^n - 1)/(b - 1)$ were tabulated for bases up to 99 and large values of n.

The purpose of this paper is to present the results of computer searches for primes of the form,

$$Q(b, n) = \frac{b^n + 1}{b + 1} \tag{1}$$

for bases up to 200 and large values of n.

2. Prime Search

For certain values of n in (1) the denominator cannot divide the numerator and are thus excluded from this study, and Q has algebraic factors for certain other values of b, n so that it cannot be prime. The algebraic factors of $b^n + 1$ can be determined using the theory of cyclotomic polynomials [4], but virtually all the important results can be obtained by simple long division. Trying long division, it is easy to see that the denominator cannot divide the numerator when n is even, and always divides it when n is odd. Also, if n is odd and composite then $b^k + 1$ will divide $b^n + 1$ when k divides n so that Q cannot be prime. Thus Q can be prime only if n is an odd prime.

For certain special forms of b, Q has algebraic factors for all n. If $b = c^t$ is a perfect power where t is greater than 2 and not a power of 2 then Q has algebraic factors and is almost always composite. There are rare cases when Q may be prime for small n but again $Q(b, n)$ can only be prime when n is prime.

It is well known that all factors of $b^n + 1$ with n an odd prime must be primes of the form $p = 2kn + 1$. We divided each $Q(b, n)$ by all primes of this form with $k < 100,000$, finding a small factor about half the time. Each remaining Q was subjected to a Fermat test

$$a^{Q-1} = 1 \pmod{Q}$$

for some $a \neq b$. If the congruence failed, then Q was composite. If it held then we tried the test again with a different a. If both tests succeeded, Q was declared a probable prime (or *prp*).

About a day was devoted to each value of b using computers with a frequency of about 500 MegaHertz. Almost all the prp searching was done by the second author.

3. Prime Proving

Small prp's up to 12 digits were proved prime by simple division. For prp's up to about 800 digits the prime proving program, APRT-CLE of UBASIC was used [5]. This program has an upper test limit of about 830 digits.

For prp's greater than 800 digits and up to 1200 digits we used the VFYPR program of Tony Forbes, which is an extended version of the UBASIC program, that can test prp's up to 1600 digits and is about twice as fast as UBASIC [7]. For a Pentium/500 it takes about 40 hours to test a 1200-digit prp and the test time increases as about the 4th power of the number of digits. The test limit of 1200 digits was arbitrarily chosen because of computer time availability.

One other prime-proving method was used in a few cases. The BLS method is based on being able to factor $Q - 1$ so that the factored part exceeds $\sqrt[3]{Q}$ [3]. Since

$$\frac{b^n + 1}{b + 1} - 1 = \frac{b(b^{n-1} - 1)}{b + 1}$$

the BLS method in this case can sometimes use the extensive results of previous factorizations for the Cunningham project and other projects to reduce prime proving times from hours to seconds.

The results are shown in the accompanying tables. An asterisk indicates a probable prime. [Numbers in square brackets give the appropriate sequence numbers in the On-Line Encyclopedia of Integer Sequences.]

Abstract: Let *S* be the set of positive integers determined by these rules:

1 is an element of *S*, and
if *x* is an element of *S*, then 2*x* and 4*x* - 1 are elements of *S*.

Let *s* be the sequence of elements of *S* arranged in increasing order. The even terms of *s* occupy ranks-past-1 given by the sequence

r = (1,3,4,6,8,9,11,12,14,16,...).

The same sequence gives the ranks of 0 's in the infinite Fibonacci word, 0100101001001010... . That is, *r*(*n*) = [*n***tau*], where *tau* = (1 + sqrt(5))/2.

Introduction

Let *S* be the "self-generating set" of positive integers determined by these rules:

1 is an element of *S*, and
if *x* is an element of *S*, then 2*x* and 4*x*-1 are elements of *S*.

We ask: how are the even numbers in *S* distributed among the odds? The question suggests arranging the elements of *S* in increasing order, which gives the sequence

(1) $s = (1,2,3,4,6,7,8,11,12,14,15,16,22,23,24,27,28,30,31,32,43,...)$.

In *s*, the evens, (2,4,6,8,12,...) and odds-past-1, (3,7,11,15,23,...), occupy positions of considerable interest. Numbering these positions *to the right of the initial* 1 yields ranks-past-1 sequences. Every positive integer lies in exactly one of these complementary sequences. In fact, these are the celebrated Beatty sequences known as the Wythoff sequences. The lower Wythoff sequence,

$r = (1,3,4,6,8,9,11,12,14,16, ...)$

is given by $r(n) = [n*tau]$, where *tau* is the golden mean, (1 + sqrt(5))/2. The complement of *r*,

$R = (2,5,7,10,13,15,18,20,23,26, ...)$,

called the upper Wythoff sequence, satisfies $R(n) = n + [n*tau]$.

We note here, but do not use in the sequel, the fact that *r* and *R* give the ranks of 0 's and 1 's in the infinite Fibonacci word, 0100101001001010... , defined from an initial 0 by repeatedly substituting 01 for 0 and 0 for 1.

The entry in [2] for the sequence *s*, A052499, was contributed by Henry Bottomley, who notes that $s(F(n + 3) - 1) = 2^n$, where $F(k)$ denotes the *k*th Fibonacci number, given by the initial values and recurrence relation

$F(0) = 0, F(1) = 1, F(n + 2) = F(n) + F(n + 1)$ for $n> = 0$.

For further information about the other sequences mentioned above see A000201 (the lower Wythoff sequence), A001950 (the upper Wythoff sequence) and A003849 (the infinite Fibonacci word) in [2].

Main Result

A birds-eye view of the proof is this: establish that *s* can be generated in a manner analogous to a way of generating the sequence *t* of positive integers together with the nonnegative integer multiples of *tau*, arranged in increasing order, and then show that the evens-past-1 in *s* occupy the same positions as the positive integers in *t*.

Lemma 1. The sequence *s* in (1) is determined by its initial values and induction. We have:

(i) $s(1) = 1, s(2) = 2, s(3) = 3, s(4) = 4, s(5) = 6, s(6) = 7$.

(ii) Suppose for arbitrary $n> = 3$, $m = 3,4,...,n$ and $i = F(m + 3) - 1$ that

(2) $s(i) = 2^m$,

(3) $(s(i + 1),s(i + 2),...,s(i + F(m) - 1))$

$= (2^m + s(F(m + 1)), 2^m + s(F(m + 1) + 1), ..., 2^m + s(F(m + 2) - 2))$,

(4) $(s(i + F(m)), s(i + F(m) + 1), ..., s(i + F(m + 2) - 1))$

$= (2^m + s(F(m + 2) - 1), 2^m + s(F(m + 2)), ..., 2^m + s(F(m + 3) - 2))$.

Then equations (2)-(4) hold for all positive integers $n <= 3$.

Proof: Equations (2)-(4) clearly hold for $n = 3$. It then suffices to prove that they hold when m is replaced by $m + 1$. First, we shall show that the number of elements x in S that satisfy

(5) $2^{m + 1} <= x <= 2^{m + 2} - 1$

is $F(m + 3)$. By the induction hypothesis, the number of elements v in S such that

(6) $2^m <= v <= 2^{m + 1} - 1$

is $F(m + 2)$, and the number of elements u in S such that

(7) $2^{m - 1} <= u <= 2^{m - 1}$

is $F(m + 1)$. Each x in S is necessarily $2v$ for some v as in (6), or else $4u - 1$ for some u as in (7), with one exception: $4*2^{m - 1} - 1$ is not an x satisfying (5); on the other hand, $4*(2^m - 1) - 1$ is an x in S satisfying (5), so that the number of x in S satisfying (5) is

(8) $F(m + 2) + (F(m + 1) - 1) + 1 = F(m + 3)$.

Write $m + 1$ for m in (3), obtaining $F(m + 1) - 1$ numbers

$2^{m + 1} + s(j)$, for $j = F(m + 2), ..., F(m + 3) - 2$.

If $s(j) = 2u$ for u in S, then $2^{m + 1} + s(j) = 2*(2^m + u)$, an element of S since $2^m + u$ is an element of S. If $s(j) = 4v - 1$ for v in S, then $2^{m + 1} + s(j) = 4*(2^{m - 1} + v) - 1$ is an element of S since $2^{m - 1} + v$ is an

element of *S*. Hence the numbers on the right-hand side of (3) are all in *S*.

Write $m + 1$ for m in (4), obtaining $F(m + 2)$ numbers

$$2^{m+1} + s(j), \text{ for } j = F(m + 3), ..., F(m + 4) - 2.$$

As just proved in connection with (3), all these numbers are in *S*.

Finally, $2^{m+1} = 2*2^m$, in *S*. To summarize, equation (8) counts the $F(m + 3)$ numbers in *S* that appear on the left-hand sides of (2)-(4), and the $F(m + 3)$ numbers on the right-hand sides of (2)-(4) have been proved to be in *S*. It is now noted that, by induction, these numbers on the right-hand sides are listed in increasing order, hence in the same order as those on the left-hand sides.

We turn now to a comparable development of the lower Wythoff sequence. Let $N = \{1,2,3,...\}$ and $T = N$ *UNION* $\{k*tau : k = 0,1,2,...\}$. Let *t* be the sequence of elements of *T* arranged in increasing order.

Lemma 2. The sequence *t* is determined by its initial values and induction. We have:

(i) $t(1) = 0$, $t(2) = 1$, $t(3) = tau$, $t(4) = 2$, $t(5) = 3$, $t(6) = 2*tau$.

(ii) Suppose for arbitrary $n>3$ and $m = 1,2,...,n$ and $i = F(m + 3) - 1$ that

(2') $t(i) = F(m + 2) - 1$,

(3') $(t(i + 1), t(i + 2), ..., t(i + F(m) - 1)) =$

$(w(F(m + 1)) + t(F(m + 1)), w(F(m + 1) + 1) + t(F(m + 1) + 1), ..., w(F(m + 2) - 2) + t(F(m + 2) - 2))$,

(4') $(t(i + F(m)), t(i + F(m) + 1), ..., t(i + F(m + 2) - 1)) =$

$(w(F(m + 2) - 1) + t(F(m + 2) - 1), w(F(m + 2)) + t(F(m + 2)), ..., w(F(m + 3) - 2) + t(F(m + 3) - 2))$,

where $w(j) = F(m + 1)$ if $t(j)$ is an integer, and $w(j) = tau*F(m)$ if $t(j) = k*tau$ for some integer *k*,

for $j = F(m + 1), ..., F(m + 3) - 2$. Then equations (2)-(4) hold for all positive integers $n>3$.

Proof: It is easy to check that equations (2')-(4') hold for $n = 3$. It suffices to prove that they hold when *m* is replaced by $m + 1$. Following the method of proof of Lemma 1, we shall show that the number of elements *x* in *T* that satisfy

(5') $F(m + 3) - 1 <= x <= F(m + 4) - 1$

is $F(m + 3)$. By induction hypothesis, the number of y in T such that

(6') $F(m + 2) - 1 <= y <= F(m + 3) - 1$

is $F(m + 2)$, and the number of y in T such that

(7') $F(m + 1) - 1 <= y <= F(m + 2) - 1$

is $F(m + 1)$. Therefore the number of x in T satisfying (5') is

$$F(m + 2) + F(m + 1) = F(m + 3).$$

We have $t(0) < t(1) < t(2) < t(3) < t(4) < t(5) < t(6) < t(7)$. Continuing inductively, we shall prove that the $F(m + 3)$ numbers as formulated on the right-hand sides of (2')-(4'), which are clearly in T, are in increasing order. Let $t(j) < t(j + 1)$ be neighboring terms as in (3') and (4') taken together; i.e., $F(m + 1) <= j <= F(m + 3) - 3$. We consider four cases:

Case i: $t(j)$ in N and $t(j + 1)$ in N. Here,

$$w(j) + t(j) = F(m + 1) + t(j) < F(m + 1) + t(j + 1) = w(j + 1) + t(j + 1).$$

Case ii: $t(j)$ in N and $t(j + 1) = k*tau$ for some k in N. If m is odd, then $w(j) = F(m + 1) < tau*F(m) = w(j + 1)$, so that

(9) $$w(j) + t(j) = F(m + 1) + t(j) < tau*F(m) + k*tau = w(j + 1) + t(j + 1).$$

If m is even, we must work harder: $F(m + 1)/F(m)$ is a convergent to tau, hence a best approximation (Lang [1], 1 - 11), which means that

(10) $F(m + 1) - tau*F(m) < k*tau - [k*tau]$ for $1 <= k <= F(m + 1) - 1$.

Hence, in particular, $F(m + 1) - tau*F(m) < t(j + 1) - t(j)$ since $t(j + 1) = k*tau$ for some k as in (10), and so (9) holds.

Case iii: $t(j) = k*tau$ for some k in N and $t(j + 1)$ in N. An argument analogous to that for case ii yields

$$w(j) + t(j) = tau*F(m) + k*tau < F(m + 1) + t(j + 1) <= w(j + 1) + t(j + 1).$$

Case iv: $t(j) = k*tau$ and $t(j + 1) = (k + 1)*tau$ for some k in N. This cannot happen, since

$$k*tau < [(k + 1)*tau] <= (k + 1)*tau.$$

Thus the numbers of the right-hand sides of (2')-(4') are identical to and listed in the same order as those on the left-hand sides.

THEOREM. The ranks-past-1 sequence for even terms of s is given by $r(n) = [n*tau]$.

Proof: Lemma 1 establishes that the numbers on the right-hand sides of (2)-(4) are, in the same order,

$$s(i), s(i + 1), ..., s(i + F(m + 2) - 1),$$

where $i = F(m + 3) - 1$, for $m = 3,4,...$, and $s(i) = 2^m$. Since $s(i + F(m + 2) - 1) = 2^{m + 1} - 1$, we have

$$s(i + F(m + 2) - 1) < s(F(m + 4) - 1) < 2^{m + 1}.$$

Therefore the numbers on the right-hand sides of (2)-(4), together with the six initial values, account for the whole sequence, inductively.

Let $rho(n)$ be the rank in s, after the initial 1, of the nth even term. The six initial terms (1,2,3,4,6,7) yield $rho(1) = 1$, $rho(2) = 3$, $rho(3) = 4$, in agreement with $r(1) = 1$, $r(2) = 3$, $r(3) = 4$ as the ranks-past-0 of integers in $t = (0, 1, tau, 2, 3, 2*tau, ...)$.

In order to prove that $rho(n) = r(n)$ for all $n >= 3$, we refer again to the inductive definitions (2)-(4) and (2')-(4'). Let

$$s(j(1)), s(j(2)), ..., s(j(q)), \quad (j(1) < j(2) < ... < j(q))$$

represent the evens satisfying (2)-(4). Then the evens satisfying (5) are

$$(11) \quad 2^m + s(j(1)), 2^m + s(j(2)), ..., 2^m + s(j(q)),$$

and these have ranks determined by the subscripts on the left-hand sides of (2)-(4). Assume as an induction hypothesis that

$$t(j(1)), t(j(2)), ..., t(j(q))$$

are the integers satisfying (2')-(4'). Then the integers satisfying (5') are

$F(m + 1) + t(j(1)), F(m + 1) + t(j(2)), ..., F(m + 1) + t(j(q))$.

They have ranks determined by the subscripts on the left-hand sides of (2')-(4'). Since these subscripts exactly match those of (11), we have *rho* = *r*.

The predecessors-past-0 of the *n*th integer in *t* are the integers 1,2,...,*n* together with the [*n/tau*] irrationals *tau*, 2**tau*, ..., [*n/tau*]**tau* so that *rho*(*n*) = *n* + [*n/tau*] = [*n***tau*]. Since *r* = *rho*, we conclude that *r*(*n*) = [*n***tau*] for *n* = 1,2,3, ...

Email address: mkaneko@math.kyushu-u.ac.jp

Abstract

A direct proof is given for Akiyama and Tanigawa's algorithm for computing Bernoulli numbers. The proof uses a closed formula for Bernoulli numbers expressed in terms of Stirling numbers. The outcome of the same algorithm with different initial values is also briefly discussed.

1 The Algorithm

In their study of values at non-positive integer arguments of multiple zeta functions, S. Akiyama and Y. Tanigawa [1] found as a special case an amusing algorithm for computing Bernoulli numbers in a manner similar to "Pascal's triangle" for binomial coefficients.

Their algorithm reads as follows: Start with the 0-th row $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \dots$ and define the first row by $1\cdot(1-\frac{1}{2}), 2\cdot(\frac{1}{2}-\frac{1}{3}), 3\cdot(\frac{1}{3}-\frac{1}{4}), \dots$ which produces the sequence $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \dots$. Then define the next row by $1\cdot(\frac{1}{2}-\frac{1}{3}), 2\cdot(\frac{1}{3}-\frac{1}{4}), 3\cdot(\frac{1}{4}-\frac{1}{5}), \dots$, thus giving $\frac{1}{6}, \frac{1}{6}, \frac{3}{20}, \dots$ as the second row. In general, denoting the m-th ($m = 0, 1, 2, \dots$) number in the n-th ($n = 0, 1, 2, \dots$) row by $a_{n,m}$, the m-th number in the $(n+1)$-st row $a_{n+1,m}$ is determined recursively by

$$a_{n+1,m} = (m+1)\cdot(a_{n,m} - a_{n,m+1}).$$

Then the claim is that the 0-th component $a_{n,0}$ of each row (the "leading diagonal") is just the n-th Bernoulli numbers B_n, where

$$\sum_{n=0}^{\infty} B_n \frac{x^n}{n!} = \frac{xe^x}{e^x - 1} \left(= \frac{x}{e^x - 1} + x \right).$$

Note that we are using the definition of the Bernoulli numbers in which $B_1 = \frac{1}{2}$. This is the definition used by Bernoulli (and independently Seki, published one year prior to Bernoulli). Incidentally, this is more appropriate for the Euler formula $\zeta(1-k) = -B_k/k$ $(k = 1, 2, 3, \dots)$ for the values of the Riemann zeta function.

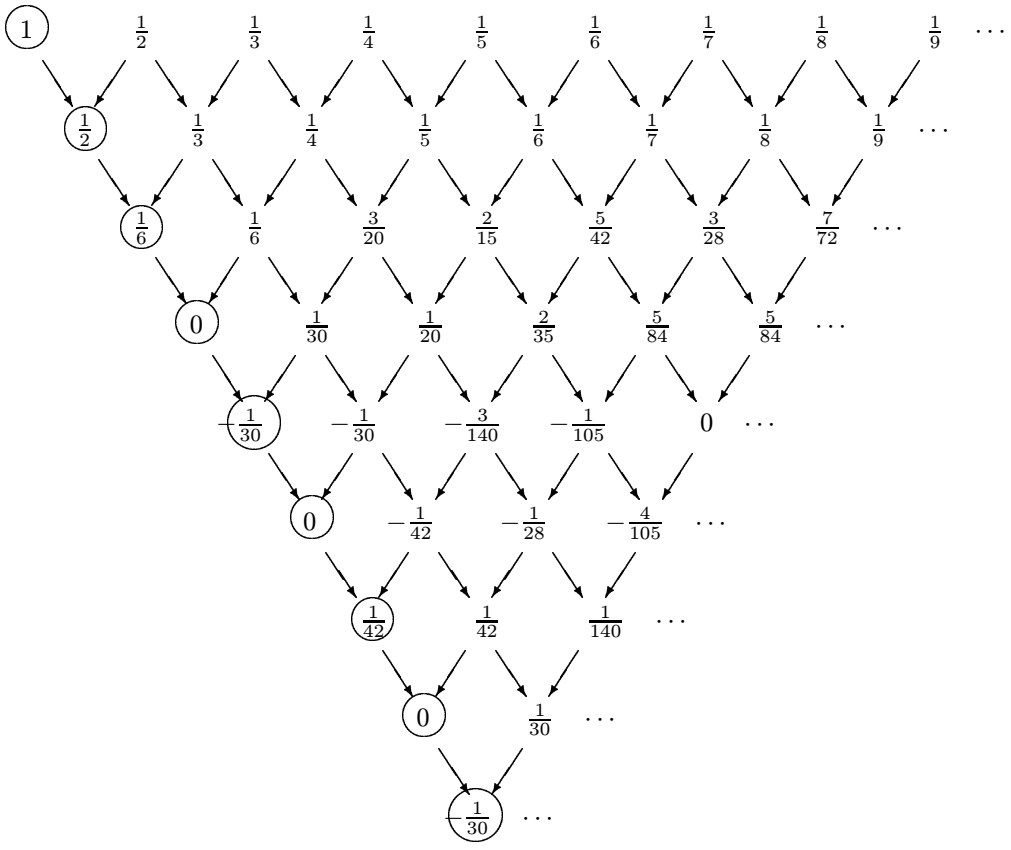

Figure 1: Akiyama-Tanigawa triangle

2 Proof

The proof is based on the following identity for Bernoulli numbers, a variant of which goes as far back as Kronecker (see [4]). Here we denote by $\left\{ {n \atop m} \right\}$ the Stirling number of the second kind:

$$x^n = \sum_{m=0}^{n} \left\{ {n \atop m} \right\} x^{\underline{m}},$$

where $x^{\underline{m}} = x(x-1)\cdots(x-m+1)$ for $m \geq 1$ and $x^{\underline{0}} = 1$. (We use Knuth's notation [7]. For the Stirling number identities that we shall need, the reader is referred for example to [5].)

Theorem 1

$$B_n = \sum_{m=0}^{n} \frac{(-1)^m m! \left\{ {n+1 \atop m+1} \right\}}{m+1}, \qquad \forall n \geq 0.$$

We shall give later a proof of this identity for the sake of completeness. Once we have this, the next proposition ensures the validity of our algorithm.

Proposition 2 *Given an initial sequence $a_{0,m}$ $(m = 0, 1, 2, \dots)$, define the sequences $a_{n,m}$ $(n \geq 1)$ recursively by*

$$a_{n,m} = (m+1) \cdot (a_{n-1,m} - a_{n-1,m+1}) \quad (n \geq 1, m \geq 0). \tag{1}$$

Then

$$a_{n,0} = \sum_{m=0}^{n} (-1)^m m! \left\{ {n+1 \atop m+1} \right\} a_{0,m}. \tag{2}$$

Proof. Put

$$g_n(t) = \sum_{m=0}^{\infty} a_{n,m} t^m.$$

By the recursion (1) we have for $n \geq 1$

$$\begin{aligned}
g_n(t) &= \sum_{m=0}^{\infty} (m+1)(a_{n-1,m} - a_{n-1,m+1}) t^m \\
&= \frac{d}{dt}\Big(\sum_{m=0}^{\infty} a_{n-1,m} t^{m+1}\Big) - \frac{d}{dt}\Big(\sum_{m=0}^{\infty} a_{n-1,m+1} t^{m+1}\Big) \\
&= \frac{d}{dt}(t g_{n-1}(t)) - \frac{d}{dt}(g_{n-1}(t) - a_{n-1,0}) \\
&= g_{n-1}(t) + (t-1)\frac{d}{dt}(g_{n-1}(t)) \\
&= \frac{d}{dt}((t-1) g_{n-1}(t)).
\end{aligned}$$

Hence, by putting $(t-1)g_n(t) = h_n(t)$ we obtain

$$h_n(t) = (t-1)\frac{d}{dt}(h_{n-1}(t)) \quad (n \geq 1),$$

and thus

$$h_n(t) = \left((t-1)\frac{d}{dt}\right)^n (h_0(t)).$$

Applying the formula (*cf.* [5, Ch. 6.7 Exer. 13])

$$\left(x\frac{d}{dx}\right)^n = \sum_{m=0}^{n} \left\{ n \atop m \right\} x^m \left(\frac{d}{dx}\right)^m$$

for $x = t-1$, we have

$$h_n(t) = \sum_{m=0}^{n} \left\{ n \atop m \right\} (t-1)^m \left(\frac{d}{dt}\right)^m h_0(t).$$

Putting $t = 0$ we obtain

$$\begin{aligned}
-a_{n,0} &= \sum_{m=0}^{n} \left\{ n \atop m \right\} (-1)^m m!(a_{0,m-1} - a_{0,m}) \\
&= \sum_{m=0}^{n-1} \left\{ n \atop m+1 \right\} (-1)^{m+1}(m+1)!a_{0,m} - \sum_{m=0}^{n} \left\{ n \atop m \right\} (-1)^m m! a_{0,m} \\
&= -\sum_{m=0}^{n} (-1)^m m! a_{0,m} \left((m+1)\left\{ n \atop m+1 \right\} + \left\{ n \atop m \right\} \right) \\
&= -\sum_{m=0}^{n} (-1)^m m! \left\{ n+1 \atop m+1 \right\} a_{0,m}.
\end{aligned}$$

(We have used the recursion $\left\{ {n+1} \atop {m+1} \right\} = (m+1)\left\{ {n} \atop {m+1} \right\} + \left\{ {n} \atop {m} \right\}$.) This proves the proposition.

Proof of Theorem 1. We show the generating series of the right hand side coincide with that of B_n. To do this, we use the identity

$$\frac{e^x(e^x-1)^m}{m!} = \sum_{n=m}^{\infty} \left\{ n+1 \atop m+1 \right\} \frac{x^n}{n!} \tag{3}$$

which results from the well-known generating series for the Stirling numbers (*cf.* [5, (7.49)])

$$\frac{(e^x-1)^m}{m!} = \sum_{n=m}^{\infty} \left\{ n \atop m \right\} \frac{x^n}{n!}$$

by replacing m with $m+1$ and differentiating with respect to x. With this, we have

$$\begin{aligned}
&\sum_{n=0}^{\infty}\left(\sum_{m=0}^{n}\frac{(-1)^m m!\left\{{n+1 \atop m+1}\right\}}{m+1}\right)\frac{x^n}{n!}\\
=\;&\sum_{m=0}^{\infty}\frac{(-1)^m m!}{m+1}\sum_{n=m}^{\infty}\left\{{n+1 \atop m+1}\right\}\frac{x^n}{n!}=\sum_{m=0}^{\infty}\frac{(-1)^m m!}{m+1}\frac{e^x(e^x-1)^m}{m!}\\
=\;&e^x\sum_{m=0}^{\infty}\frac{(1-e^x)^m}{m+1}=\frac{e^x}{1-e^x}\sum_{m=1}^{\infty}\frac{(1-e^x)^m}{m}\\
=\;&\frac{e^x}{1-e^x}\left(-\log\left(1-(1-e^x)\right)\right)=\frac{xe^x}{e^x-1}.
\end{aligned}$$

This proves Theorem 1.

Remark. A referee suggested the following interpretation of the algorithm using generating function:

Suppose the first row is $a_0, a_1, a_2, \ldots$, with ordinary generating function

$$A(x)=\sum_{n=0}^{\infty}a_n x^n.$$

Let the leading diagonal be $b_0 = a_0, b_1, b_2, \ldots$, with exponential generating function

$$\mathbb{B}(x)=\sum_{n=0}^{\infty}b_n\frac{x^n}{n!}.$$

Then we have

$$\mathbb{B}(x)=e^x A(1-e^x).$$

This follows from (2) and (3), the calculation being parallel to that of the proof of Theorem 1. To get the Bernoulli numbers we take $a_0=1, a_1=\frac{1}{2}, a_2=\frac{1}{3},\ldots$ with $A(x)=-\log(1-x)/x$, and find $\mathbb{B}(x)=xe^x/(e^x-1)$.

3 Poly-Bernoulli numbers

If we replace the initial sequence $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots$ by $1, \frac{1}{2^k}, \frac{1}{3^k}, \frac{1}{4^k}, \ldots$ and apply the same algorithm, the resulting sequence is $(-1)^n D_n^{(k)}$ $(n=0,1,2,\ldots)$, where $D_n^{(k)}$ is a variant of "poly-Bernoulli numbers" ([6], [2], [3]): For any integer k, we define a sequence of numbers $D_n^{(k)}$ by

$$\frac{Li_k(1-e^{-x})}{e^x-1}=\sum_{n=0}^{\infty}D_n^{(k)}\frac{x^n}{n!},$$

where $Li_k(t)=\sum_{m=1}^{\infty}\frac{t^m}{m^k}$ (k-th polylogarithm when $k\geq 1$). The above assertion is then a consequence of the following (or, is just a special case of the preceding remark)

Proposition 3 *For any $k \in \mathbf{Z}$ and $n \geq 0$, we have*

$$D_n^{(k)} = (-1)^n \sum_{m=0}^{n} \frac{(-1)^m m! \left\{ {n+1 \atop m+1} \right\}}{(m+1)^k}.$$

Proof. The proof can be given completely in the same way as the proof of Theorem 1 using generating series, and hence will be omitted.

Acknowledgements

I should like to thank the referee for several comments and suggestions.

The Number-Wall Algorithm: an LFSR Cookbook

W. F. Lunnon
Department of Computer Science
National University of Ireland
Maynooth, Co. Kildare, Ireland
Email address: fred@cs.may.ie

Abstract: This paper might fairly be said to fall between three stools: the presentation and justification of a number of related computational methods associated with LFSR sequences, including finding the order, recurrence and general term; the exploration of tutorial examples and survey of applications; and a rigorous treatment of one topic, the recursive construction of the number wall, which we believe has not previously appeared.

The *Number Wall* is the table of Toeplitz determinants associated with a sequence over an arbitrary integral domain, particularly **Z**, $\mathbf{F_p}$, **R**, and their polynomial and series extensions by many variables. The relation borne by number walls to LFSR (linear recurring shift register) sequences is analogous to that borne by difference tables to polynomial sequences: They can be employed to find the order and recurrence (Section 3), or to compute further terms and express the general term explicitly (Section 10) - a lthough other more elaborate methods may be more efficient (Sections 8 and 12).

Much of the paper collects and summarizes relevant classical theory in Formal Power Series (Section 1), Linear Recurrences (Section 2), Padé Blocks (essentially) (Section 3), Vandermonde Interpolation (Section 8), and Difference Tables (Section 9). A `frame' relation between the elements of the number wall containing zeros (a *non-normal C-table*, in Padé terminology) is stated and proved (Section 4), with the resulting recursive generation algorithm and some special cases (Section 5); the consequences of basing the wall on this algorithm instead are explored (Section 6), and a cellular automaton is employed to optimize it in linear time (Section 7).

The connections between number walls and classical Padé tables are discussed briefly (Section 11), with other associated areas (Linear Complexity, QD Algorithm, Toda Flows, Berlekamp-Massey) reviewed even more briefly (Section 12). Among topics covered incidentally are the explicit number wall for an

LFSR, in particular for a diagonal binomial coefficient (Section 8); dealing with high-degree `polynomials' over finite fields, fast computation of LFSR order over $\mathbf{F}_p$, and the wall of a linear function of a given sequence (Section 9). There are numerous examples throughout, culminating in a final gruelingly extensive one (Section 13).

0. Introduction and Acknowledgements

The initial aim of this rambling dissertation was to codify what J. H. Conway has christened the *Number Wall*, an efficient algorithm for computing the array of Toeplitz determinants associated with a sequence over an arbitrary integral domain: particularly interesting domains in this context are integers $\mathbf{Z}$, integers modulo a prime $\mathbf{F}_p$, reals $\mathbf{R}$, and their polynomials and power series extensions. §1 (Notation and Formal Laurent Series) sketches elementary the algebraic machinery of these domains and their pitfalls, and §2 (LFSR Sequences) summarizes the elementary theory of Linear Feedback Shift Registers.

Our original program is now carried out with an earnest aspiration to rigor that may well appear inappropriate (and may yet be incomplete): however, on numerous occasions, we discovered the hard way that to rely on intuition and hope for the best is an embarrassingly unrewarding strategy in this deceptively elementary corner of mathematical folklore. In §3 (Determinants and Zero-windows) we define the number wall, give simple algorithms for using it to determine the order and recurrence of an LFSR, establish the recursive construction rule in the absence of zeros (a.k.a. the Sylvester Identity) and the square window property of zeros (a.k.a. the Padé Block Theorem) which, despite of its great age and simplicity of statement, appears to have evaded a substantial number of previous attempts to furnish it with a coherent demonstration. In §4 (The Frame Theorems) we develop the central identities connecting elements around inner and outer frame of a window of zeros in a wall; equally contrary to expectation, these prove to be a notably delicate matter! §5 (The Algorithm, Special Cases) discusses the recursive algorithm implicit in the Frame Theorems, particularly the special cases of an isolated zero and of a binary domain, and digressing along the way to an instructive fallacy which felled a earlier attempted proof. §6 (General Symmetric Walls) explores the consequences of employing this oddly symmetric algorithm — rather than the original Toeplitz determinant — to build a generalized wall from an arbitrary pair of sequences of variables or numerals. We show the denominators are always monomial, and that there is arbitrarily large long-range dependence; and give some striking examples. §7 (Performance and the FSSP) explores how an apparently unrelated idea from Cellular Automaton Theory — Firing Squad Synchronization — plays a major part in tuning a fast computational algorithm, which has actually been implemented for the binary domain.

At this point in writing, the focus shifted rather towards a survey of existing methods, as it became apparent that — while much if not all of this material is known by somebody — there is no collected source reference for a whole batch of elementary computational problems associated with LFSRs. §8 (Interpolation and Vandermonde Matrices) summarizes classical material which is used to find explicitly the coefficients needed in §10, digressing to give explicitly the wall for binomial coefficient diagonals, and a formula for the general element of the wall in terms of the general element of the sequence in the LFSR case. §9 (Difference Tables) takes a look at a venerable ancestor, the difference table being to polynomials what the number wall (in a more general way) is to linear recurrences. Appropriate definition and effective evaluation of a polynomial are nontrivial for finite characteristic; the ensuing investigation leads *inter alia* to a fast algorithm for computing the order of an LFSR over $\mathbf{F}_p$, applicable to a recent study of deBruijn sequences. At least some of these strands are pulled together in §10 (Explicit Term of an LFSR Sequence) where we discuss efficient methods of computing the roots and coefficients of the 'exponential' formula for the general element of an LFSR sequence from a finite set of its elements.

In §11 (Padé Tables) we make the classical connection between number walls and rational approximation, and develop some pleasantly straightforward algorithms for series reciprocal and ('non-normal') Padé approximants. §12 (Applications and Related Algorithms) surveys applications including linear complexity profiles (LCPs) and numerical roots of polynomials (Rutishauser QD), with a brief description of the well-known Berlekamp-Massey algorithm for computing the recurrence of an LFSR sequence from its elements. Finally §13 (Hideous Numerical Example) features an intimidating computation, intended to illustrate some of the nastier aspects of the Outer Frame Theorem, and succeeding we fear only too well.

As a third strand, we have felt obliged to make this something of a tutorial, and to that end have sketched proofs for the sake of completeness wherever practicable: existing proofs of well-known results in this area seem often to be difficult of access, incomplete, over-complicated or just plain wrong. We have included frequent illustrative examples, some of which we hope are of interest in their own right; and a number of conjectures, for this is still an active research area (or would be if more people knew about it).

It would be surprising if much of the material presented here was genuinely new — we have been scrupulous in acknowledging earlier sources where known to us — but we felt it worth collating under a

uniform approach. We originally unearthed the Frame Theorems over 25 years ago, and although the result might now quite reasonably be considered to lie in the public domain, to the best of our knowledge no complete proof has ever been published. We trust it is at last in a form fit for civilized consumption: if so, some of the credit should go to the numerous colleagues who have persistently encouraged, struggled with earlier drafts, and made suggestions gratefully incorporated — in particular Simon Blackburn, David Cantor, John Conway, Jim Propp, Jeff Shallit, Nelson Stephens.

1. Notation and Formal Laurent Series

For applications we are interested principally in sequences over the integers $\mathbf{Z}$ or a finite field $\mathbf{F}_p$, especially the binary field. However, to treat these cases simultaneously, as well as to facilitate the proofs, we shall need to formulate our results over an arbitrary ground *integral domain*, i.e. a commutative ring with unity and without divisors of zero. Such a domain may be extended to its field of fractions by **Her75** §3.6, permitting elementary linear algebra, matrices and determinants to be defined and linear equations to be solved in the usual way; and further extended to its ring of polynomials and field of (formal) Laurent power series in a transcendental variable, following a fairly routine procedure to be expounded below.

There is rarely any need for us to distinguish between variables over these different domains, so they are all simply denoted by italic capitals. Integer variables (required for subscripts etc, whose values may include $\pm\infty$ where this makes sense) are denoted by lower-case italic letters. Vectors, sequences and matrices are indicated by brackets — the sequence $[S_n]$ has elements $\ldots, S_0, S_1, S_2, \ldots$, and the matrix $[F_{ij}]$ has determinant $|F_{ij}|$. A sequence is implicitly infinite in both directions, where not explicitly finite; context should suggest if a truncated segment requires extrapolation by zero elements, periodic repetition, or the application of some LFSR.

In §4 the elements are actually polynomials over the ground domain; and all the quantities we deal with could be expressed as rational functions (quotients of polynomials) over it. While it is both feasible and conceptually simpler to couch our argument in terms of these, the mechanics of the order notation $\mathcal{O}(X^k)$ introduced below become unnecessarily awkward; therefore we prefer to utilize the slightly less familiar concept of *Formal Laurent Series* (FLS).

We define the field of FLS to be the set of two-sided sequences $[\ldots, S_k, \ldots]$ whose components lie in the given ground field, and which are *left-finite*, that is only finitely many components are nonzero for $k < 0$. Arithmetic is defined in the usual Taylor-Laurent power-series fashion: that is, addition and negation are term-by-term, multiplication by Cauchy (polynomial) product, reciprocal of nonzeros by the binomial expansion. The ground field is injected into the extension by $S_0 \to [\ldots, 0, S_0, 0, \ldots]$.

As usual we write an FLS as an infinite sum of integer powers of the transcendental X with finitely many negative exponents: its *generating function*. The notation is suggestive, but has to be interpreted with some care. For instance, we cannot in general map from FLSs to values in the ground field by substituting some value for X, since this would require the notion of convergence to be incorporated in the formalism. Fortunately we have no need to do so here, since we only ever *specialize* $X \to 0$, defined simply as extracting the component S_0 with zero subscript.

The following property is deceptively important in subsequent applications.

> **Theorem:** Specialization commutes with FLS arithmetic: that is, if $W(V(X), \ldots)$ denotes some (arithmetic) function of FLS elements $V(X), \ldots$, and $V(0)$ denotes $V(X)$ with $X \to 0$ etc, then $W(V(0), \ldots) = W(V(X), \ldots)(0)$. (1.0)

Proof: This is the case $k = 0$ of the nontrivial fact that two FLSs $U = [\ldots, S_k, \ldots]$ and $V = [\ldots, T_k, \ldots]$ are equal under the operations of field arithmetic (if and) only if they are equal component-wise, that is only if $S_k = T_k$ for all k. For suppose there existed distinct sequences $[S_k], [T_k]$ for which $U = V$ arithmetically. Then $U - V = 0$, where the sequence corresponding to $U - V$ has some nonzero component. Using the binomial expansion, we calculate its reciprocal; now $1 = (U - V)^{-1} \cdot (U - V) = (U - V)^{-1} \cdot 0 = 0$. So the field would be trivial, which it plainly is not, since it subsumes the ring of polynomials in X. ■

In this connection it is instructive to emphasize the significance of left-finiteness. If this restriction were abandoned, we could consider say (expanding by the binomial theorem)

$$\begin{aligned} U &= 1/(1-X) = 1 + X^1 + X^2 + X^3 + \ldots, \\ -V &= X^{-1}/(1-X^{-1}) = \ldots + X^{-3} + X^{-2} + X^{-1}; \end{aligned}$$

now by elementary algebra $U = V$ despite the two distinct expansions, and (1.0) would no longer hold. Related to this difficulty is the fact that we no longer have a field: $U - V$ for instance, the constant unity sequence, has no square.

One unwelcome consequence is that the generating function approach frequently employed as in **Nie89** to discuss Linear Complexity is applicable only to right- (or mut. mut. left-) infinite sequences, and is unable to penetrate the 'central diamond' region of a number-wall (§3) or shifted LCP (§12), being restricted to a region bounded to the South by some diagonal line. [It is noteworthy that, elementary as they might be, these matters have on occasion been completely overlooked elsewhere in the literature.]

Definition: For FLS U, the statement

$$U = \mathcal{O}(X^k) \tag{1.1}$$

shall mean that $U_l = 0$ for $l < k$.

It is immediate from the definition that

$$\begin{aligned}
0 &= \mathcal{O}(X^\infty); \\
U + \mathcal{O}(X^k) &= U + \mathcal{O}(X^l) \\
&\quad \text{for } l \le k \text{ (asymmetry of equality)}; \\
(U + \mathcal{O}(X^k)) \pm (V + \mathcal{O}(X^l)) &= (U \pm V) + \mathcal{O}(X^{\min(k,l)}); \\
(U + \mathcal{O}(X^k)) \cdot (V + \mathcal{O}(X^l)) &= (U \cdot V) + \mathcal{O}(X^{\min(k+n,l+m)}) \\
&\quad \text{if } U = \mathcal{O}(X^m) \text{ and } V = \mathcal{O}(X^n); \\
(U + \mathcal{O}(X^k))/(V + \mathcal{O}(X^l)) &= (U/V) + \mathcal{O}(X^{\min(k-n,l+m)}) \\
&\quad \text{if in addition } V_n \neq 0, \text{ so } n \text{ is maximal.}
\end{aligned}$$

Notice that we can only let $X \to 0$ in $U + \mathcal{O}(X^k)$ if $k > 0$, otherwise the component at the origin is undefined; and in practice, we only ever do so when also $U = \mathcal{O}(1)$. In §4 – §5 we shall implicitly make extensive use of these rules.

For completeness, we should perhaps mention the more usual classical strategy for ensuring that a set of FLSs forms a field: to define convergence and enforce it, say over some annular region of the domain of complex numbers. The connection with our counterexample above is of course that any S, T corresponding to the same meromorphic function in distinct regions will give $U - V = 0$. The elementary definitions and algorithms of FLS arithmetic are fully discussed in standard texts such as **Hen74** §1.2, or **Knu81** §1.2.9 and §4.7. With the exception of the thorough tutorial **Niv69**, these authors consider only the ring of formal Taylor series with exponents $k \ge 0$; however, it is a fairly routine matter to extend the ring to a field, and there seems little reason to constrain oneself in this manner.

2. LFSR Sequences

A sequence S_n is a *linear recurring* or *linear feedback shift register* (LFSR) sequence when there exists a nonzero vector $[J_i]$ (the *relation*) of length $r+1$ such that

$$\sum_{i=0}^{r} J_i S_{n+i} \;=\; 0 \quad \text{for all integers } n.$$

The integer r is the *order* of the relation. If the relation has been established only for $a \le n \le b-r$ we say that the relation *spans* (at least) $S_a, \ldots, S_b$, with $a = -\infty$ and $b = +\infty$ permitted. LFSR sequences over finite fields are discussed comprehensively in **Lid86** §6.1–6.4.

It is usual to write a relation as an *auxiliary* polynomial $J(\mathbf{E})$ of degree r in the *shift* operator $\mathbf{E}:\ S_n \to S_{n+1}$:

Definition: The LFSR sequence $[S_n]$ satisfies the relation $J(\mathbf{E})$ just when for all n

$$J(\mathbf{E})[S_n] \;\equiv\; \sum_i J_i \mathbf{E}^i [S_n] \;\equiv\; \sum_i J_i [S_{n+i}] \;=\; [O_n], \tag{2.1}$$

the zero sequence (with order 0 and relation $J(\mathbf{E}) \;=\; 1$).

Notice that the number of nonzero components or *dimension* of a relation as a vector is in general $r+1$, two relations being regarded as equal (as for projective homogeneous coordinates) if they differ only by some nonzero constant multiple; also in the case of sequences whose values are given by a polynomial in n §9, the *degree* of the polynomial is in general $r-1$.

The *order* of a sequence (infinite in both directions) is normally understood to mean the minimum order of any relation it satisfies; this *minimal* relation is simply the polynomial highest common factor of all relations satisfied by the sequence, and is therefore unique. [The existence of such an HCF is guaranteed by the Euclidean property of the ring of polynomials in a *single* variable $\mathbf{E}$ over the ground domain, see **Her75** §3.9.] The leading and trailing coefficients J_r, J_0 of the minimal relation J of a (two-way-infinite) sequence are nonzero: such relations we shall call *proper*. These definitions must be interpreted with care when applied to segments with finite end-points, principally because even minimal relations may fail to be proper: both leading and trailing zero coefficients will then need to be retained during polynomial arithmetic on relations. Furthermore, if the minimum order is r and the span has length $< 2r$, a minimal relation is no longer unique, since there are too few equations to specify its coefficients.

By the elementary theory (**Lid86** §6.2) we have an explicit formula for an LFSR sequence:

Theorem: $[S_n]$ satisfies $J(\mathbf{E})[S_n] \;=\; [O_n]$ just when

$$S_n \;=\; \sum_i K_i {X_i}^n \quad \text{for all } n, \tag{2.2}$$

where the X_i are the roots of $J(X)$ and the K_i are coefficients, both lying in the algebraic closure of the ground domain when $J(X)$ has distinct roots; when the root X_i occurs with multiplicity e_i, K_i is a polynomial in n of degree $e_i - 1$.

Proof: Since we make frequent reference to this well-known result, we sketch a demonstration for the sake of completeness. [Over ground domains of finite characteristic, it is important that the 'polynomials' $K_i(n)$ are defined in terms of binomial coefficients; we return to this point in §9.]

From the Pascal triangle recursion, by induction on e

$$\begin{aligned} (\mathbf{E}-1)\binom{n}{e-1} \;&=\; \binom{n}{e-2}, \\ (\mathbf{E}-1)^e \binom{n}{e-1} \;&=\; 0; \end{aligned} \tag{2.3}$$

and so by expressing the arbitrary polynomial $K(n)$ of degree $e-1$ in n as a linear combination of binomial coefficients, we see that its e-th difference $(\mathbf{E}-1)^e K(n)$ is zero. Similary $(\mathbf{E}-X)X^n = 0$ and $(\mathbf{E}-X)^e K(n)X^n = 0$ for arbitrary X. Suppose S_n has the explicit form above (2.2), where $J(X)$ has just m distinct roots; let $X \equiv X_m$ etc., and let primes denote the analogous expressions involving only the other $m-1$ roots; then

$$\begin{aligned} J(\mathbf{E})S_n &= \prod_i (\mathbf{E}-X_i)_i^e S_n \\ &= J'(\mathbf{E})\big((\mathbf{E}-X)^e K(n)X^n\big) + (\mathbf{E}-X)^e\big(J'(\mathbf{E})S'_n\big) \\ &= J'(\mathbf{E})(0) + (\mathbf{E}-X)^e(0) = 0 \end{aligned}$$

for all n, using induction on m.

The converse can be approached constructively as in **Lid86** (who prove the distinct case only) by setting up linear equations for the K_i and showing that they possess a unique solution, as we shall do in (8.6) (for distinct X_i) and (9.2) (for coincident X_i effectively). In the general case of multiple roots, it is simpler to observe that the set of sequences satisfying a given relation J (assumed to possess nonzero leading and trailing coefficients) comprise a vector space **Her75** §4 whose dimension must be r, since each is completely determined by its initial r terms. The set constructed earlier is also a subspace of dimension r, so the two sets are identical by **Her75** Lemma 4.1.2. ■

If J is minimal then all the K_i are nonzero: for the Galois group of an irreducible factor of J is transitive on those X_i and their corresponding K_i while leaving S_n invariant, so those K_i must all be nonzero or all zero. In the latter case, J may be divided by the factor and so is not minimal. When all the roots coincide at unity, S_n equals an arbitrary polynomial of degree $r-1$ in n; so the latter are seen to be a special case of LFSR sequences.

3. Determinants and Zero-windows

Given some sequence $[S_n]$, we define its *Number Wall* (also *Zero Square Table* or — misleadingly — *QD Table*) $[S_{m,n}]$ to be the two dimensional array of determinants given by

Definition:

$$S_{m,n} = \begin{vmatrix} S_n & S_{n+1} & \dots & S_{n+m} \\ S_{n-1} & S_n & \dots & S_{n+m-1} \\ \vdots & \vdots & \ddots & \vdots \\ S_{n-m} & S_{n-m+1} & \dots & S_n \end{vmatrix}. \tag{3.1}$$

The value of $S_{m,n}$ is defined to be unity for $m=-1$, and zero for $m<-1$. [These are known as *Toeplitz* determinants; or, with a reflection making them symmetric, and a corresponding sign change of $(-1)^{\binom{m+1}{2}}$, as *persymmetric* or *Hankel* determinants.] The rows and columns are indexed by m, n resp. in the usual orientation, with the m axis increasing to the South (bottom of page) and n to the East (right). [For examples see the end of §5 and elsewhere.]

Lemma: For any sequence $[S_n]$ and integers n and $m \geq 0$, we have $S_{m-1,n} \neq 0$ and $S_{m,n} = 0$ just when there is a proper linear relation of minimum order m spanning at least $S_{n-m}, \dots, S_{n+m}$. Its coefficients J_i are unique up to a common factor. Further, when

$$S_{m,n} = S_{m,n+1} = \dots = S_{m,n+g-1} = 0 \quad \text{and} \quad S_{m,n-1} \neq 0,\ S_{m,n+g} \neq 0 \tag{3.2}$$

the relation maximally spans $S_{n-m}, \dots, S_{n+m+g-1}$. [Notice that we may have $n=-\infty$ or $g=+\infty$.]

Proof: by elementary linear algebra. For $g = 1$, set up $m + 1$ homogeneous linear equations for the J_i, with a unique solution when they have rank m:

$$\begin{aligned} S_{n-m}J_0 \ + \ S_{n-m+1}J_1 \ + \ \ldots \ + \ S_nJ_m \ &= \ 0, \\ &\vdots \\ S_nJ_0 \ + \ S_{n+1}J_1 \ + \ \ldots \ + \ S_{n+m}J_m \ &= \ 0, \\ &\vdots \\ S_{n+g-1}J_0 \ + \ S_{n+g}J_1 \ + \ \ldots \ + \ S_{n+m+g-1}J_m \ &= \ 0. \end{aligned}$$

Using $S_{n-m+1}, \ldots, S_{n+m+1}$ on the right-hand side instead of $S_{n-m}, \ldots, S_{n+m}$ leaves m of these equations unaltered, so by induction on g the solution is constant over the whole segment of $[S_n]$ of length $2m + g$, and no further. This solution is proper: for if $J_m = 0$ there would be a nontrivial solution to the equations with m replaced by $m - 1$, and so we should have $S_{m-1,n} = 0$ contrary to hypothesis; similarly if $J_0 = 0$. Similarly, it is minimal. Conversely, if a there is a relation, then $S_{m,n} = 0$; if it is minimal, then it is unique, and if it is also proper then m cannot be reduced, so $S_{m-1,n} \neq 0$. ■

Corollary: $[S_n]$ is an LFSR sequence of order r if and only if row r (and all subsequent rows) of its number-wall degenerate to the zero sequence, but row $r - 1$ does not. (3.3)

Given as many terms as we require of an LFSR sequence $[S_n]$, we can use (3.3) to compute its order r from its number-wall. Now suppose in addition we require to find the linear relation $J(\mathbf{E})$ which generates it. We introduce a new sequence of polynomials in a transcendental X over the domain, defined by

$$U_n(X) \ = \ (\mathbf{E} - X)S_n \ = \ S_{n+1} - X.S_n,$$

and form its number wall $U_{m,n}(X)$. If we set $X \to \mathbf{E}$, both sequence and wall (for $m \neq -1$) perforce degenerate to all zeros; therefore each $U_{m,n}(\mathbf{E})$ is a relation spanning those $2m + 2$ elements of $[S_n]$ from which it was computed. Now for degree r there is only one such polynomial (modulo a constant factor), and that is the required minimal relation $J(\mathbf{E})$: for all n therefore, $U_{r-1,n}$ equals $J(X)$ multiplied by some domain element (nonzero since setting $X \to 0$ gives the wall for $[S_n]$ itself); and similarly $U_{r-1,n} = 0$ on all subsequent rows $m \geq r$.

Corollary: $[S_n]$ is an LFSR sequence of order r if and only if row r (and all subsequent rows) of the number-wall of $S_{n+1} - X.S_n$ degenerate to the zero sequence, but row r does not; then row $r - 1$ equals the minimal relation $J(X)$ of $[S_n]$ times a geometric sequence over the ground domain. (3.4)

This algorithm is slower than the more sophisticated Berlekamp-Massey method (12.1), taking time of order r^4 arithmetic operations over the ground domain (using straightforward polynomial multiplication) rather than r^2; but it is noticeably easier to justify, and it also gives the relations of intermediate (odd) spans.

A simple recursive rule for constructing the number-wall of a given sequence in the absence of zeros is classical, and follows immediately from the pivotal condensation rule styled by **Ioh82** §1.2 the *Sylvester Identity* [described by **Ait62** §45 as an *extensional* identity due to Jacobi, and elsewhere credited to Desnanot, Dodgson or Frobenius]:

Lemma: Given an $m \times m$ matrix $[F_{ij}]$ and an arbitrary $(m - k) \times (m - k)$ minor $[G_{ij}]$ where $0 \leq k \leq m$, define H_{ij} to be the cofactor in $|F|$ selecting all the rows and columns of $|G|$, together with the i-th row and j-th column not in $|G|$. Then (3.5)

$$|F_{ij}| \ \times \ |G_{ij}|^{k-1} \ = \ |H_{ij}|.$$

Proof: We may suppose the elements of $[F_{ij}]$ to be distinct variables transcendental over the ground domain, thus avoiding any problem with singular matrices. We may also suppose the rows and columns of $[F_{ij}]$ permuted so that $[G_{ij}]$ occupies the SE corner, $i, j > k$: this leaves the determinant unaltered except for a possible change of sign. Consider the matrix $[E_{ij}]$ with E_{ij} being F_{ij} when $i > k$, or $|G|$ bordered by row i and column j of F when $i \leq k$. Expanding this determinant by its first row, we see (with some difficulty — the reader is advised to work through a small example) that

$$E_{ij} \;=\; |G| F_{ij} \;+\; \sum_q A_{iq} F_{iq},$$

where the A_{iq} are cofactors from the last $m-k$ rows which do not depend on j. So $[E_{ij}]$ is effectively $[F_{ij}]$ with each of its first k rows multiplied by $|G|$, then subjected to a sequence of elementary column operations which leave the determinant unaltered. On the one hand then, $|E| = |F| \times |G|^k$.

Again,

$$E_{ij} \;=\; \begin{cases} H_{ij} & \text{for } 1 \leq i \leq k \text{ and } 1 \leq j \leq k \text{ by definition,} \\ G_{ij} & \text{for } k < i \leq m \text{ and } k < j \leq m \text{ by definition,} \\ 0 & \text{for } 1 \leq i \leq k \text{ and } k < j \leq m \text{ (determinant with equal columns).} \end{cases}$$

So on the other hand $|E| = |H| \times |G|$. Canceling the nonzero $|G|$ from $|E|$ gives the result. ■

Theorem: A symmetrical relation between the elements of the number-wall is

$$S_{m,n}^2 \;=\; S_{m+1,n} S_{m-1,n} \;+\; S_{m,n+1} S_{m,n-1}. \tag{3.6}$$

Proof: In (3.5) choose $k = 2$, $|F_{ij}| = S_{m+1,n}$, and $|G_{ij}| = S_{m-1,n}$ where this last is the cofactor occupying the interior of $[F_{ij}]$. Then the H_{ij} also turn out to be entries in the wall, and we find

$$S_{m+1,n} \times S_{m-1,n} \;=\; \begin{vmatrix} S_{m,n} & S_{m,n+1} \\ S_{m,n-1} & S_{m,n} \end{vmatrix}. \;\blacksquare$$

Corollary: A partial recursive construction for the number-wall is

$$\begin{aligned} S_{-2,n} \;&=\; 0, \quad S_{-1,n} \;=\; 1, \quad S_{0,n} = S_n, \\ S_{m,n} \;&=\; \big({S_{m-1,n}}^2 \;-\; S_{m-1,n+1} S_{m-1,n-1} \big) / S_{m-2,n} \quad \text{for } m > 0, \\ &\qquad \text{provided } S_{m-2,n} \neq 0. \end{aligned} \tag{3.7}$$

[The initial row of zeros is not a great deal of use at this point, but comes in useful later as an *outer frame* for zeros occurring in the sequence.]

The possibility of zero elements in the wall is a stumbling block to the use of (3.7) for its computation, particularly if the ground domain happens to be a small finite field, when they are almost certain to occur. The next result sharpens a classical one in the study of Padé Tables §11, the first half of the 'Padé Block Theorem'. All proofs of it (including this author's) should be regarded with suspicion, having a disconcerting tendency to resort to hand-waving at some crucial point in the proceedings: for this reason we feel regretfully unable to recommend a prior version.

A *region* of a number wall is defined to be a simply-connected subset of elements, where two elements are *connected* when they have one subscript (m or n) equal, the other (n or m) differing by unity. The regions which we consider are $g \times g'$ *rectangles*, having at most four boundary segments along each of which some subscript is constant; their *lengths* g, g' (measured in numbers of elements along each segment) may range from zero to infinity. The *inner frame* of a rectangle is the smallest connected set which disconnects the

region from its complement: it normally comprises four edges and four corners. The *outer frame* similarly disconnects the union of the rectangle with its inner frame from the complement. [In the example at the end of §5 will be found a 4×4 (square) rectangle of zeros, with an inner frame of ones.]

Theorem: Square Window Theorem: Zero elements $S_{m,n} = 0$ of a number-wall occur only within *zero-windows*, that is square $g \times g$ regions with nonzero inner frames. The nullity of (the matrix corresponding to) a zero element equals its distance h from the inner frame. (3.8)

Proof: To start with, by (3.6) if $S_{m-1,n} = S_{m,n-1} = 0$ then $S_{m,n} = 0$, and by (3.6) shifting $m \leftarrow m-1, n \leftarrow n-1$, similarly $S_{m-1,n-1} = 0$; the mirror-image argument yields the converse. Now by an easy induction, any connected region of zeros must be a (possibly infinite) rectangle.

Now let there be such a rectangle with g rows, g' columns, and NW corner (n increasing to the East and m to the South) located at $S_{m,n}$: in detail,

$$\begin{aligned}
S_{m,n} = 0,\ \ldots,\ S_{m,n+g'-1} &= 0;\\
S_{m,n} = 0,\ \ldots,\ S_{m+g-1,n} &= 0,\\
S_{m,n+g'-1} = 0,\ \ldots,\ S_{m+g-1,n+g'-1} &= 0,\\
S_{m+g-1,n} = 0,\ \ldots,\ S_{m+g-1,n+g'-1} &= 0,\\
S_{m-1,n} \neq 0,\ \ldots,\ S_{m-1,n+g'} &\neq 0;\\
S_{m,n} \neq 0,\ \ldots,\ S_{m+g,n} &\neq 0;\\
S_{m,n+g'} \neq 0,\ \ldots,\ S_{m+g,n+g'} &\neq 0;\\
S_{m+g,n} \neq 0,\ \ldots,\ S_{m+g,n+g'} &\neq 0.
\end{aligned}$$

Then by (3.2) a unique minimal relation $J(\mathbf{E})$ of order m spans $S_{n-m}, \ldots, S_{n+m+g-1}$. Suppose $g' > g$: then the relation $\mathbf{E}^g J$ of order $m+g$ spans $S_{n-m-g}, \ldots, S_{n+m+g}$, so by (3.2) $S_{m+g,n} = 0$, contrary to hypothesis. Suppose $g' < g$: then since $S_{m+g',n} = 0$, there is a relation spanning $S_{n-m-g'}, \ldots, S_{n+m+g'}$; also since $S_{m+g'-1,n-1} \neq 0$ is a nonzero minor of $S_{m+g',n}$, the latter has nullity 1 and the relation must therefore be unique. One such relation is simply $\mathbf{E}^{g'} J$: so J spans $S_{n-m+g'}, \ldots, S_{n+m+g'}$ and by (3.2) $S_{m,n+g'} = 0$, contrary to hypothesis. The only possibility remaining is that $g' = g$, and the rectangle must be a square.

Consider this square divided by its diagonals $i - j = m - n$ and $i + j = m + n + g - 1$ into North, East, South, West quarters; let h denote the distance of the element $S_{i,j}$ from the frame in the same quarter. All the elements in the North quarter have rank m, since the only relations spanning subintervals of $S_{n-m}, \ldots, S_{n+m+g-1}$ are (polynomial) multiples of J itself: in particular, if g is odd, the central element has rank m and nullity $h = [(g+1)/2]$. If g is even, there are four elements at the centre, the North pair having rank m and nullity h as before; the South pair have rank $m+1$, since (for example) any relation corresponding to $S_{m+g/2,n+g/2-1}$ spans $S_{m-n-1}, \ldots, S_{n+m+g/2}$, but S_{m-n-1} lies outside the span of J (the relations are multiples of $\mathbf{E}J$). So for any g the central elements have nullity equal to their distance h from the frame. Now observe that the nullity of any element $S_{i,j}$ can only differ from that of its neighbors $S_{i-1,j}, S_{i,j-1}, S_{i,j+1}, S_{i+1,j}$ by at most unity, since the matrices differ essentially by a single row or column. Therefore it must decrease with h in all directions, in order to reach zero with h at the inner frame where all elements are nonzero. ■

A simple consequence of (3.8) is the occurrence of 'prime windows' in a wall over some larger ground domain:

Corollary: Elements divisible by some prime ideal P clump together in square regions, elements at distance h from the frame being divisible by (at least) P^h. (3.9)

In particular, these windows are noticeable for ordinary primes p in integer walls.

A less obvious but more useful and rather elegant consequence, credited to Massey in **Cha82**, quantifies the notion that, if two different sequences have a large common portion, then at least one of them has high linear order. It could be proved directly by linear dependence arguments.

Corollary: Massey's Lemma: The sum of the orders of proper relations spanning two intervals of a sequence exceeds the length of the intersection, unless each relation spans their union. (3.10)

Proof: Let the intervals (a_i, b_i) of the sequence be spanned maximally by minimal proper relations of orders r_i, for $i = 1, 2$. By (3.2), (3.8) there are corresponding windows in the number-wall at (m_i, n_i) of size g_i where $a_i = n_i - m_i$, $b_i = n_i + m_i + g_i - 1$, so

$$m_i = r_i, \quad n_i = a_i + r_i, \quad g_i = b_i - a_i - 2r_i + 1.$$

Suppose the windows to be distinct (failing which their parameters coincide in pairs); since they are square and cannot overlap, one of the following is true:

$$m_1 + g_1 < m_2, \quad n_1 + g_1 < n_2, \quad m_2 + g_2 < m_1, \quad n_2 + g_2 < n_1.$$

Substituting, either

$$\begin{cases} b_1 - a_1 - r_1 + 1 < r_2 & \text{or} \\ b_1 - r_1 + 1 < a_2 + r_2 & \text{or} \\ b_2 - a_2 - r_2 + 1 < r_1 & \text{or} \\ b_2 - r_2 + 1 < a_1 + r_1 \end{cases}$$

whence

$$r_1 + r_2 \ > \ 1 + \min(b_1 - a_1, b_1 - a_2, b_2 - a_2, b_2 - a_1).$$

as claimed.

Relaxing the maximality constraint on the intervals and the minimality on the order does not affect the result. ■

As an illustration, suppose we are to find the order and relation spanning

$$S \ = \ [0, 0, 0, 1, 16, 170, 1520, 12411, 96096, 719860, \ldots].$$

The following pair of number-walls can be computed via (3.6): The final row of zeros of the first suggests (3.3) that the order might be $r = 4$. The final row of the second gives (3.4) the auxiliary polynomial $J \ = \ \mathbf{E}^4 - 16\mathbf{E}^3 + 86\mathbf{E}^2 - 176\mathbf{E} + 105 \ = \ 0$, that is S satisfies the relation

$$S_{n+4} - 16S_{n+3} + 86S_{n+2} - 176S_{n+1} + 105S_n \ = \ 0.$$

$m\backslash n$	0	1	2	3	4	5	6	7	8	9
−2	0	0	0	0	0	0	0	0	0	0
−1	1	1	1	1	1	1	1	1	1	1

	$105-176X+86X^2-16X^3+X^4$			

4. The Frame Formulae

We are now ready to tackle the central undertaking of this investigation: the elucidation of conditions on the number-wall elements of the inner and outer frames surrounding a zero-window, permitting the recursive rule (3.7) to be completed. The results to be proved are as follows, the adjacent diagram illustrating the notation employed, to be explained in more detail as we proceed.

Diagram Window Notation

	E_0	E_1	E_2	$\ldots$	E_k	$\ldots$	E_g	E_{g+1}	
F_0	B, A_0	A_1	A_2	$\ldots$	A_k	$\ldots$	A_g	A, C_{g+1}	G_{g+1}
F_1	B_1	$\mathbf{0}$	$\mathbf{0}$	$\ldots$	$\mathbf{0}$	$\ldots$	$\mathbf{0}$	C_g	G_g
F_2	B_2	$\mathbf{0}$	$\ddots$	(P)	$\rightarrow$		$\vdots$	$\vdots$	$\vdots$
$\vdots$	$\vdots$	$\vdots$	(Q)	$\ddots$		$\uparrow$	$\mathbf{0}$	C_k	G_k
F_k	B_k	$\mathbf{0}$	$\downarrow$		$\ddots$	(R)	$\vdots$	$\vdots$	$\vdots$
$\vdots$	$\vdots$	$\vdots$		$\leftarrow$	(T)	$\ddots$	$\mathbf{0}$	C_2	G_2
F_g	B_g	$\mathbf{0}$	$\ldots$	$\mathbf{0}$	$\ldots$	$\mathbf{0}$	$\mathbf{0}$	C_1	G_1
F_{g+1}	B, D_{g+1}	D_g	$\ldots$	D_k	$\ldots$	D_2	D_1	D, C_0	G_0
	H_{g+1}	H_g	$\ldots$	H_k	$\ldots$	H_2	H_1	H_0	

Theorem: Frame Ratio Theorem: The inner frame of a $g \times g$ zero-window comprises four geometric sequences, along the North, West, East, South edges, with ratios P, Q, R, T resp., and origins at the NW and SE corners. They satisfy

$$PT/QR \;=\; (-)^g; \tag{4.1}$$

Corollary: Inner Frame Theorem: The inner frame sequences A_k, B_k, C_k, D_k satisfy

$$A_k D_k / B_k C_k \;=\; (-)^{gk} \quad \text{for } 0 \le k \le g+1; \tag{4.2}$$

Theorem: Outer Frame Theorem: The outer frame sequences E_k, F_k, G_k, H_k lie immediately outside A_k, B_k, C_k, D_k resp., and are aligned with them. They satisfy the relation: For $g \ge 0$, $0 \le k \le g+1$,

$$QE_k/A_k \;+\; (-)^k PF_k/B_k \;=\; RH_k/D_k \;+\; (-)^k TG_k/C_k. \tag{4.3}$$

The method of proof is straightforward in principle: unfortunately, the details are somewhat involved. Suppose we are given an *original* sequence $[S_n]$ with elements in some given ground domain, such that the number wall displays a $g \times g$ zero-window with NW corner $S_{m,n}$. We proceed to modify one element by adding a transcendental

$$S_{n+m+g-1} \;\leftarrow\; S_{n+m+g-1} + (-)^m X,$$

yielding a *perturbed* sequence over the domain extended to formal power series, whose (perturbed) wall has only a $(g-1) \times (g-1)$ zero-square at the same location.

Now assuming the exact result for the smaller zero-window over the extension, we proceed to prove it by induction for the perturbed wall, then finally let $X \to 0$ [i.e. specialize to FLS coefficient of X^0]. To avoid unnecessarily complicating an already quite sufficiently involved notation, we do not explicitly distinguish between the original and perturbed quantities; but claims referring to the latter are styled *Lemma* rather than *Theorem*, and explicitly involve X. We make heavy implicit use of our $\mathcal{O}(X^k)$ notation and rules (1.1).

Here we digress to emphasize that, for this induction to take effect, the perturbed configuration must itself constitute the number wall of some actual sequence; the importance of this will subsequently be underlined by a counterexample (5.4). Failure to respect this principle fatally compromised at least one earlier attempted proof of an essentially equivalent result — credited to Gilewicz and Froissart in **Gil78** — where the postulated configuration of four perturbed inner edges, each linear in the perturbing variable, can be seen by (4.5) to be impossible. [It is intriguing to speculate how such a strategy might have come to be preferred over that adopted here. A partial explanation may lie in the various other pitfalls awaiting us below, which shall duly be paraded for the reader's edification.]

Diagram Perturbed Window Notation

	E_0	E_1	E_2	$\dots$	E_k	$\dots$	$\dots$	E_g	E_{g+1}	
F_0	B, A_0	A_1	A_2	$\dots$	A_k	$\dots$	$\dots$	A_g	A, C_{g+1}	G_{g+1}
F_1	B_1	$\mathbf{0}$	$\mathbf{0}$	$\dots$	$\mathbf{0}$	$\dots$	$\mathbf{0}$	M_g	C_g	G_g
F_2	B_2	$\mathbf{0}$	$\ddots$	(P)	$\rightarrow$		$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\vdots$	$\vdots$	$\vdots$	(Q)	$\ddots$		$\uparrow$	$\mathbf{0}$	M_k	C_k	G_k
F_k	B_k	$\mathbf{0}$	$\downarrow$		$\ddots$	(R)	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\vdots$	$\vdots$	$\vdots$		$\leftarrow$	(T)	$\ddots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\vdots$	$\vdots$	$\mathbf{0}$	$\dots$	$\mathbf{0}$	$\dots$	$\dots$	$\mathbf{0}$	M_2	C_2	G_2
F_g	B_g	N_g	$\dots$	N_k	$\dots$	$\dots$	N_2	N, M_1	C_1	G_1
F_{g+1}	B, D_{g+1}	D_g	$\dots$	D_k	$\dots$	$\dots$	D_2	D_1	D, C_0	G_0
	H_{g+1}	H_g	$\dots$	H_k	$\dots$	$\dots$	H_2	H_1	H_0	

The perturbed window is illustrated in the accompanying Diagram, representing a region within the perturbed wall, for some sequence which is not shown. Below and on the counter diagonal, all perturbed elements are polynomial (finite FLS); above it, they remain as original. The original zero-window had inner frame comprising A, B, C, D and outer frame E, F, G, H on its North, West, East, South sides; the perturbed window has inner frame M, N (where originally there were zeros) and outer frame C, D on its East, South. The frame vectors are of length $g + 2$ (original) or $g + 1$ (perturbed), indexed from 0: the origin of North frame vectors is on column $n-1$, of West on row $m-1$ (A_0 and B_0 are identical), of East on row $m+g$, and of South on column $n+g$ (C_0 and D_0 are identical). It will emerge that A, B, C, D, M, N are approximately geometric sequences (4.5) – (4.7), their ratios denoted by $A_1/A_0 = P, Q, R, T, U, V$ respectively.

Lemma: There are elements U, V such that for $1 \le k \le g+1$,

$$\begin{aligned} M_k \;&=\; A_g U^{k-g-1}, \quad N_k \;=\; B_g V^{k-g-1}; \\ \text{in fact,} \quad U \;&=\; P/X, \quad V \;=\; (-)^{g-1} Q/X. \end{aligned} \tag{4.5}$$

Proof: By definition (3.1)

$$M_g \;=\; \begin{vmatrix} S_{n+g-1} & \cdots & S_{n+g+m-1} + (-)^m X \\ \vdots & \ddots & \vdots \\ S_{n+g-m-1} & \cdots & S_{n+g-1} \end{vmatrix}$$

$$= \begin{vmatrix} S_{n+g-2} & \cdots & S_{n+g+m-3} \\ \vdots & \ddots & \vdots \\ S_{n+g-m-1} & \cdots & S_{n+g-2} \end{vmatrix} X \;+\; \begin{vmatrix} S_{n+g-1} & \cdots & S_{n+g+m-1} \\ \vdots & \ddots & \vdots \\ S_{n+g-m-1} & \cdots & S_{n+g-1} \end{vmatrix},$$

expanding the determinant;

$$= \; A_{g-1} X \;+\; 0$$

in terms of the original wall. Also $M_{g+1} \equiv A_g$, so we can define

$$U \;=\; M_{g+1}/M_g \;=\; A_g/A_{g-1}X, \quad \text{or} \quad U \;=\; P/X.$$

For N, V, Q the only difference is that the determinant is order $m+g-1$; notice that we can use the same X in both contexts, by (3.8). Finally, for $1 \le k \le g-1$, by (3.6), ${M_{k+1}}^2 = M_{k+2} M_k$, showing that $[M_k]$ is geometric with ratio U; similarly for N. ■

Lemma: There are elements P, Q such that for $0 \le k \le g+1$,

$$A_k \;=\; A_0 P^k \;+\; \mathcal{O}(X), \quad B_k \;=\; B_0 Q^k \;+\; \mathcal{O}(X). \tag{4.6}$$

Proof: For $0 \le k \le g$, see the end of the proof of (4.5) with $P = A_1/A_0$, $Q = B_1/B_0$. For $k = g+1$, using (3.6) and (4.6) [A is exactly geometric for $k < g+1$], we have

$$A_{g+1} \;=\; ({A_g}^2 - E_g M_g)/A_{g-1} \;=\; A_0 P^{g+1} - E_g X.$$

B behaves similarly. ■

It is important to bear in mind that we may always divide by elements of the inner frame or by ratios, since we know these to be nonzero; indeed the same is true of C and D, even in the perturbed case (4.7). And when multiplying or dividing FLSs (1.1), we need to ascertain that the factors have order sufficiently large to justify the order claimed for the error in their product: E, F, G, H are always $\mathcal{O}(1)$ at worst; A, B, C, D and P, Q, R, T are $\mathcal{O}(1)$ exactly; but U, V are $\mathcal{O}(1/X)$.

Notice here too that the 'ratios' R, T of the approximately geometric outer frames are defined explicitly by $C_1/C_0, D_1/D_0$, rather than retaining their original values, an apparently insignificant detail which is central to the proof: it allows us to get an unexpectedly small and explicit first perturbation term in the expansions (4.7) of C, D, without which the crucial information carried by the perturbation term in the proof of the central result (4.9) would be swamped by noise of order $\mathcal{O}(X)$.

Lemma: There are elements R, T such that for $2 \le k \le g+1$,

$$\begin{aligned} C_k \;&=\; C_0 R^k \;-\; (R/P)^{g-k+3} G_{k-1} X^{g-k+2} \;+\; \mathcal{O}(X^{g-k+3}), \\ D_k \;&=\; D_0 T^k \;-\; (-)^{(g-1)k} (T/Q)^{g-k+3} H_{k-1} X^{g-k+2} \;+\; \mathcal{O}(X^{g-k+3}). \end{aligned} \tag{4.7}$$

Proof: By induction on k. For $k = 1$ we have $C_1 = C_0 R$ exactly by definition; the Lemma fails here, but still $C_1 = C_0 R + \mathcal{O}(X^{g+1})$ as required to commence the induction. For $2 \leq k \leq g+1$,

$$\begin{aligned} C_k &= {C_{k-2}}^{-1}({C_{k-1}}^2 - M_{k-1}G_{k-1}) \quad \text{by (3.6)}, \\ &= {C_0}^{-1}R^{2-k}({C_0}^2 R^{2k-2} - A_g(X/P)^{g-k+2}G_{k-1}) + \mathcal{O}(X^{g-k+3}), \end{aligned}$$

by (4.5) and hypothesis or definition; now we get the result since by (4.6) and the previous line

$${C_0}^{-1}A_g = \big({C_{g+1}}^{-1}R^{g+1} + \mathcal{O}(X)\big)\big(A_{g+1}P^{-1} + \mathcal{O}(X)\big) = R^{g+1}/P + \mathcal{O}(X).$$

D_k is treated similarly. ■

We proceed to the perturbed forms of the Frame Ratio and Outer Frame Theorems. The form of Lemma (4.9) demands some explanation. As explained earlier, the sequence and its wall have been perturbed so that the window of size g has shrunk to size $g-1$, and the natural approach would seem to be simply to apply the original Outer Frame Theorem (4.3) to compute the perturbed row D inductively, then find H immediately by (3.6) as $H_k = ({D_k}^2 - D_{k-1}D_{k+1})/N_k$: the idea is illustrated towards the end of §13.

There are several reasons why this program fails in a formal context. To begin with, finding one H_k would require three elements from D, which in turn involve three from E and F, rather than the single one demanded by the Theorem (4.3) to be proved. Then we should need to divide by $N_k = \mathcal{O}(X^{g-1-k})$ by (4.5): this implies that all terms of smaller order in the numerator must cancel, so requires pre-evaluation of this many terms of the polynomials D_k. Finally similar reasons demands the polynomials C_k, which would have to be calculated in some unrelated fashion, since we have only one equation connecting E, F, C, D: to wit (4.3) with C, D playing the part of G, H etc. [It is a fairly safe bet that (4.3) is the only condition possible on the outer frame elements, since by manipulating the original sequence, we can arrange for E,F,G to take arbitrary values. Consequential alterations to the inner frame, being fixed by just four elements A_0, P, Q, R, have little influence on this situation.]

Lemma:

$$PT/QR = (-)^g + \mathcal{O}(X^{g+1}). \tag{4.8}$$

Proof: By (4.5), $QU/PV = (-)^{g-1}$ (avoiding induction on g); and using (4.5) with $k = 2$ and (4.7) with $k = g$ (both of which in fact need no error term)

$$\begin{aligned} N_2/M_2 &= B_g V^{1-g}/A_g U^{1-g} \\ &= A_0 P^g (X/P)^{g-1}/B_0 Q^g (X/Q)^{g-1}(-)^{(g-1)^2} = V/U, \end{aligned}$$

noting that $A_0 = B_0$ and $(g-1)^2$, $(g-1)$ have the same parity; also by (4.7)

$$C_1/D_1 = C_0 R/D_0 T = R/T.$$

Collecting,

$$\begin{aligned} QR/PT &= (QU/PV)(V/U)(R/T) = (-)^g N_2 C_1/M_2 D_1 \\ &= (-)^g(-M_2 D_1 + M_1^2)/M_2 D_1 \quad \text{by (3.6)} \\ &= -(-)^g + \mathcal{O}(X^{g+1}) \quad \text{by (4.5).} \ \blacksquare \end{aligned}$$

Lemma: For $g \geq 0$, $0 \leq k \leq g+1$,

$$QE_k/A_k + (-)^k PF_k/B_k = RH_k/D_k + (-)^k TG_k/C_k + \mathcal{O}(X) \tag{4.9}$$

Proof in cases $k = 0, g+1$: By (3.6) and definition of P, Q, R, T,

$${A_0}^2 = B_1 E_0 + A_1 F_0 = A_0 Q E_0 + A_0 P F_0,$$

whence ${A_0}^{-1}(QE_0 \ + \ PF_0) \ = \ 1$; similarly ${C_0}^{-1}(RH_0 \ + \ TG_0) \ = \ 1$. Also $A_0 = B_0$ and $C_0 = D_0$, which proves case $k = 0$; case $k = g + 1$ is similar.

Proof in cases $1 \le k \le g$: For $g = 0$ there are no (further) cases to consider. For $g \ge 1$, we assume (4.9), replacing g by $g - 1$ for the induction; C_k, D_k, G_k, H_k by M_{k+1}, N_{k+1}, C_{k+1}, D_{k+1}, noticing the shift in origin caused by the new SE corner; R, T by U, V; and letting $X \to 0$. Then by inductive hypothesis

$$\begin{aligned}
&Q.E_k/A_k \ + \ (-)^k P.F_k/B_k \\
&\quad = \ U.D_{k+1}/N_{k+1} \ + \ (-)^k V.C_{k+1}/M_{k+1} \\
&\quad = \ (P/X)(-)^{(g+1)k} {B_g}^{-1} (X/Q)^{k-g} D_{k+1} \\
&\qquad + \ (-)^{k+g+1}(Q/X){A_g}^{-1}(X/P)^{k-g} C_{k+1} \ + \ \mathcal{O}(X) \quad \text{by (4.5)} \\
&\quad = \ Y + Z + \mathcal{O}(X^{g-k+2}) \ + \ \mathcal{O}(X), \quad \text{say.}
\end{aligned}$$

At this point we expand C, D by (4.7) and separate them into main Y, first perturbation Z and residual error terms. The main terms cancel to order X, as expected:

$$\begin{aligned}
Y &= X^{k-g-1}(-)^{g+k+1}\big((-)^{gk+g+1} D_0 {B_g}^{-1} Q^{-g} (T/Q)^k PT \ + \ C_0 {A_g}^{-1} P^{-g} (R/P)^k QR\big) \\
&= \ X^{k-g-1}(-)^{g+k+1} A_0 C_0 \big((-)^{gk+g+1}(T/Q)^k PT + (R/P)^k QR\big) \\
&\quad \text{since } B_g Q^{-g} = B_0 = A_0 = A_g P^{-g},\ D_0 = C_0; \\
&= \ X^{k-g-1}(-)^{g+k+1} A_0 C_0 (R/P)^k QR(-1+1) \ + \ \mathcal{O}(X^{g+1}) \\
&\quad \text{since } T/Q = (-)^g R/P + O(X^{g+1}),\ PT = (-)^g QR \ + \ \mathcal{O}(X^{g+1}) \text{ by (4.8)}; \\
&= \ \mathcal{O}(X^k).
\end{aligned}$$

The first perturbation terms incorporate the desired right-hand side:

$$\begin{aligned}
Z &= (-)^{g+k}\big((-)^k {B_g}^{-1} P Q^{-2} T^{g-k+2} H_k \ + \ {A_g}^{-1} P^{-2} Q R^{g-k+2} G_k\big) \\
&\quad \text{simplifying — the exponents of X cancel exactly;} \\
&= \ (-)^{g+k}\big((-)^k (PT/QR) R H_k/D_k + (QR/PT) T G_k/C_k\big) \ + \ \mathcal{O}(X) \\
&\quad \text{since } A_g P R^{g-k+1} = C_k \ + \ \mathcal{O}(X) \text{ etc by (4.6) then (4.7) with } k = g+1; \\
&= \ R H_k/D_k \ + \ (-)^k T G_k/C_k \ + \ \mathcal{O}(X) \quad \text{by (4.8).}
\end{aligned}$$

Collecting Y, Z, etc and checking that the error terms are all $\mathcal{O}(X)$ now gives the result. ■

Finally, setting $X \to 0$ in (4.8) and (4.9), we are home and dry in the original wall: (4.1) and (4.3) are immediate, and (4.2) is a simple consequence of (4.8), (4.6), (4.7). However, notice that this last step is only possible because specialization commutes with arithmetic (1.0).

5. The Algorithm, Special Cases

By isolating T, D_k and H_k on the left-hand side of the Frame Theorems, we immediately get a comprehensive and efficient recursion for computing the number-wall by induction on rows m:

Corollary: If $m \leq 0$ or $S_{m-2,n} \neq 0$ use (3.7); otherwise, determine whether $S_{m,n}$, with respect to the zero-window immediately to the North, lies within:
(i) the interior, when by (4.1)

$$S_{m,n} = 0 \quad \text{and} \quad T \;=\; (-)^g QR/P;$$

(ii) the inner frame, when by (4.2)

$$S_{m,n} \;\equiv\; D_k \;=\; (-)^{gk} B_k C_k / A_k; \tag{5.1}$$

(iii) the outer frame, when by (4.3)

$$S_{m,n} \;\equiv\; H_k \;=\; (D_k/R)(QE_k/A_k + (-1)^k (PF_k/B_k - TC_k/M_k)).$$

Illustrative examples are given later in this section.

In principle the original Sylvester recursion (3.6) might be dispensed with, since the Frame Theorems hold even for $g = k = 0$; but in practice it is impossible to avoid programming the latter as a special case anyway, so the saving is only conceptual. [To quote Alf van der Poorten **Poo96**: In theory, there is no difference between theory and practice. In practice, it doesn't quite work that way.]

The special case $g = k = 1$ can be recast in the simplified form:

Corollary: In the notation of the attached figure depicting a portion of the number-wall, for an isolated zero at W we have $ED^2 + HA^2 = FC^2 + GB^2$; (5.2)

this follows directly by setting $W = 0$ in the (polynomial) identity:

Lemma: In the notation of the attached figure

$$ED^2 + HA^2 - W(EH + AD) \;=\; FC^2 + GB^2 - W(FG + BC). \tag{5.3}$$

$$\begin{array}{ccccc} & & E & & \\ & L & A & K & \\ F & B & W & C & G \\ & N & D & M & \\ & & H & & \end{array}$$

Proof: Suppose W transcendental over the ground domain of $[S_n]$ [strictly, W is some not-identically-vanishing function of transcendental X, such as $W = LX$ where $L \neq 0$ and X is the perturbation of $[S_n]$ in the proof of (4.5)]. Expanding $LK \cdot NM = LN \cdot KM$ via (3.6) then rearranging,

$$(A^2 - EW)(D^2 - HW) \;=\; (B^2 - FW)(C^2 - GW),$$

$$(BC + AD)(AD - BC) \;+\; W(FC^2 + GB^2 - ED^2 - HA^2) \;+\; W^2(EH - FG) \;=\; 0.$$

Again using (3.6), substituting for $BC + AD \;=\; W^2$, canceling W and rearranging gives the desired equation. We can now argue, as in the proof of (3.5), that for fixed m this is a polynomial identity in elements of a sequence $[S_n]$ of distinct transcendentals, so it remains true even when some of the constituent elements such as W take zero values. Alternatively, in the spirit of §7, we can examine each possible pattern of zeros individually, and resolve it by applying (3.8), (4.2) for various $g \leq 3$. ■

[The above approach is noteworthy by reason of its beguiling unreliability: not only does equation (5.2) possess more symmetry than the general Outer Frame Theorem — obstructing attempts to guess the latter — but we have so far been unable to construct an analogous identity for the the $g = 2$ case, even though already in possession of (4.3). The analytically motivated proof technique conceals a pitfall, on which we now dilate.] We have been careful throughout to ensure that every table considered is actually the valid number wall of some sequence. To emphasize that this is not merely some pedantic logical conceit, we give a simple example to illustrate the consequences of abandoning this restriction during a proof, irrelevant though it might be to the initial formulation of a conjecture.

Consider the portion of a number wall shown (diagram left), where the NW zero is S_{mn}, say, and the three zeros are all isolated.

.	.	E	.	.		.	.	E	.	.		.	.	E	.	.

By (5.2) and (3.6) we have $FY^2 = EZ^2$ and $Y^2 = AX$, $Z^2 = BX$; substituting the latter into the former gives $EBX = FAX$, from which we cancel X to get $EB = FA$. Letting $X \to 0$, by (3.8) $Y, Z \to 0$ also, leaving a 3×3 window (diagram centre) for which we have established the engagingly succinct

Canard: Fool's Frame Theorem: In the notation of the diagram, there is reason to believe that

$$EB \;=\; FA. \tag{5.4}$$

Sadly, the attached period 6 wall over $\mathbf{Z}$, where $A = E = 1$, $F = 2$, $B = 4$, offers little comfort to anyone disposed to give this credence.

0	0	0	0	0	0	0	0	0
1	1	1	1	1	1	1	1	1
−1	−1	1	1	1	1	1	−1	−1
2	2	2	0	0	0	2	2	2
4	0	4	0	0	0	4	0	4
8	−8	8	0	0	0	8	−8	8
16	−16	16	−16	16	−16	16	−16	16
0	0	0	0	0	0	0	0	0

What went wrong? We could just shrug and say 'where's the sequence?'; but for the sake of explaining the phenomenon a little more convincingly, let us temporarily abandon the formal algebraic context and restrict the wall to some continuous ground domain such as $\mathbf{R}$, in particular interpreting $X \to 0$ as the familiar limit operator.

By (3.2), if $Z \neq 0$ then there is a proper relation of order $m + 2$ spanning $S_{n-m-2}, ..., S_{n+m+2}$; and if $A \neq 0$, $Y = 0$, there is a proper relation of order m spanning $S_{n-m}, ..., S_{n+m+2}$. Then as $X \to 0$, by continuity both claims become true. The sum of the orders is $2m + 2$ and the length of the intersection is $2m + 3$, so by a minor abuse of (3.10) the two relations must be identical. Hence the limiting configuration is actually a window of size 5×5 with NW corner at $S_{m,n-2}$ (diagram right): in particular, $F = B = 0$, and (5.4) is actually true for the subset of number walls to which we have inadvertently restricted ourselves — it's just not very interesting.

A second interesting special case of the Frame Theorems occurs when the ground domain is the binary field $\mathbf{F}_2$: The frame ratios P, Q, R, S and inner frames A, B, C, D are nonzero, so they must all be unity, and the algorithm reduces to

Corollary: Over the binary field, $S_{m,n} = 0$ in the interior of a window, $S_{m,n} = 1$ along its inner frame, and $S_{m,n} \equiv H_k = E_k + F_k + G_k \pmod 2$ along its outer frame. (5.5)

We illustrate (5.5) with a rather more extensive example of a number-wall. $[S_n]$ is the minimal order binary deBruijn sequence (see §9) with period [1111000011010010], and binary wall as in the Diagram (periodic horizontally, zero above and below vertically):

Diagram Binary Wall

3	1	1	1	1	0	0	0	0	1	1	1	0	1	1	0	0
4	1	0	0	1	1	1	1	1	1	0	1	1	1	1	0	0
5	1	0	0	1	0	1	0	0	1	1	1	1	0	1	1	1
6	1	1	1	1	1	1	0	0	1	0	0	1	1	1	1	0
7	1	0	0	0	0	1	1	1	1	0	0	1	1	0	1	1
8	1	0	0	0	0	1	0	0	1	1	1	1	1	1	1	0
9	1	0	0	0	0	1	0	0	1	1	1	0	0	1	1	1
10	1	0	0	0	0	1	1	1	1	0	1	0	0	1	0	1
11	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
12	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

For example, assuming rows $m < 7$ already to hand, we can immediately complete the 4×4 window of zeros with NW corner at $(m, n) = (7, 1)$, together with its inner frame of ones. Once rows $m < 12$ are to hand, we can find element $(12, 0)$ by (3.7), then element $(12, 1)$ by (5.5) with $k = 4$, $E = S_{5,4} = 0$, $F = S_{10,15} = 1$, $G = S_{7,6} = 1$, $H = S_{12,1} = 0 + 1 + 1 = 0 \pmod 2$. The final row of zeros shows that the order over the binary domain is $r = 12$.

If instead we regard $[S_n]$ as defined over the integers, the following wall results. To find element $(10, 7)$ from previous rows we can employ (5.2) with $A, B, C, D \;=\; 3, 6, 3, -6$ and $E, F, G = -2, 1, 1$, getting

$$H \;=\; (FC^2 + GB^2 - ED^2)/A^2 \;=\; (1.9 + 1.36 + 2.36)/9 \;=\; 13.$$

To find find our way around the window at $(0, 4)$ with $g = 4$ demands the full works: happily $P = Q = R = 1$ so $T = 1$ by (4.1), $A = B = C = 1$ so $D = 1$ by (4.2), and we find say element $(5, 7)$ by (4.3) with $k = 1$ and $E, F, G = 0, 1, 3$, $H = (QE/A - PF/B + TG/C)D/R = 2$. The order over the integer domain is $r = 13$.

Diagram Integer Wall

Finally, it is natural to ask is whether a simple recursive algorithm exists for number walls over more general ground rings, in particular over $\mathbf{Z}/q\mathbf{Z}$ for q an arbitrary natural number. [The obvious approach, to compute the wall over $\mathbf{Z}$ and then reduce (mod q), is less than ideal since the intermediate integers may be very large.] If $q = \prod_k {p_k}^{e_k}$ is expressed as a product of prime powers, the residue (mod q) can be computed easily from residues (mod p^e) via the Chinese Remainder Theorem **Dav88** §A.5.1, reducing the problem to the case $q = p^e$. By (3.8), the power of p (or in general, any prime ideal) dividing an element at distance h from the frame within a zero-window (mod p) must be at least p^h, and one might naïvely hope that perhaps it might be exactly p^h (it needn't); or failing that, the frames might behave in a fashion which generalizes the situation modulo p, involving the excess over p^h near a particular point on the frame. However, it is easy to construct a wall modulo $q = 4$ with a large window (mod 2) which is also perfectly square (mod 4), but for which the outer frame sum $E + F + G + H$ varies irregularly between 0 and 2 (mod 4) — strongly suggesting that the hope is unjustified. [However some progress in this area has been made — see **Ree85**.]

6. General Symmetric Walls

We now need no longer rely on the determinant approach (3.1) to define the number-wall, but may generate it instead by placing an arbitrary pair of sequences $[T_n], [S_n]$ on rows $m = -1, 0$ — subject to zero-windows (3.8), and supplemented where necessary by consistent frame data around such windows — then employing frame recursion (5.1) for $m > 0$, and by reflection for $m < -1$. The unexpected square-tiling symmetry of the new definition is noteworthy: Since neither m nor n appears explicitly, we have invariance under 2-D translations; furthermore, despite an apparent asymmetry of (3.1) between m and n, (4.1) – (4.3) are invariant under reflection in diagonals of the window, and under half-turn about its centre. [This last is rather less mysterious when viewed in the context of Padé tables §11, where it arises directly from the fact that the reciprocal transpose of the Padé table for $F(X)$ is the table for $1/F(X)$.] To distinguish the new wall from the *special number wall* (SNW) of (3.1) etc, we refer to it as a *general symmetric wall* (GSW). [It must be admitted that at the moment this construction, as was memorably observed of an entirely different subject, fills a much-needed gap.]

The elements of a GSW are plainly rational functions in the elements from which they are generated; and it seems reasonable to suppose that they should possess some explicit characterization, analogous to (3.1) defining the SNW. Such an expression would undoubtedly be immediately useful (see below), but at present we have in lieu only the following partial result, initially communicated to us by Jim Propp as a corollary of a more general combinatorial expression in **Rob86**.

Theorem: For $m \geq 1$, the general element $S_{m,n}$ of a GSW constructed (via (3.7)) from sequences of variables $S_{-1,n} = U_n$ and $S_{0,n} = V_n$ is of the form $S_{m,n} = W_{m,n}/Z_{m,n}$, where $W_{m,n}$ is an irreducible polynomial of total degree (at most) $2(m^2 - m + 1)$ in the assorted variables, and $Z_{m,n}$ is (a factor of) the degree $m^2 + (m-1)^2$ monomial

$$Z_{m,n} \;=\; \prod_{k=1-m}^{k=m-1} {U_{n+k}}^{m-|k|} {V_{n+k}}^{m-1-|k|}. \tag{6.1}$$

For $m < 0$, immediately by symmetry

$$S_{m,n}(\ldots, U_k, \ldots, V_k, \ldots) \;=\; S_{-1-m,n}(\ldots, V_k, \ldots, U_k, \ldots).$$

Proof: Notice that in the setting of a GSW, both m and n subscripts may be arbitrarily translated; so without loss of generality, we may represent an arbitrary element $S_{m,n}$ by $S_{4,4}$. By (3.6),

$$S_{44} \;=\; (S_{34}^2 - S_{33}S_{35})/S_{24}. \tag{6.2}$$

Also, substituting for the $S_{3,j}$,

$$S_{44} \;=\; \big(S_{24}^2 - S_{23}S_{25})^2/S_{14}^2 - (S_{23}^2 - S_{22}S_{24})(S_{25}^2 - S_{24}S_{26})/S_{13}S_{15}\big)/S_{24}.$$

Most of the terms in the numerator of the right-hand side above have a factor S_{24}, the exceptions simplifying to

$$-S_{23}S_{25}^2(S_{14}^2 - S_{13}S_{15})/S_{13}S_{14}^2S_{15}S_{24} \;=\; -S_{04}S_{23}S_{25}^2S_{24}/S_{13}S_{14}^2S_{15}S_{24}$$

using (3.6); so S_{24} cancels completely from the denominator, giving

$$S_{44} \;=\; \frac{S_{13}S_{15}S_{24}^3 - 2S_{13}S_{15}S_{23}S_{24}S_{25} - S_{14}^2S_{22}S_{24}S_{26} + S_{14}^2S_{23}^2S_{26} + S_{14}^2S_{22}S_{25}^2 - S_{04}S_{23}^2S_{25}^2}{S_{13}S_{14}^2S_{15}}. \tag{6.3}$$

We proceed by induction on m: elementary computation as above establishes (6.1) for $m = 1, 2$. For $m > 2$, translating (6.2) and (6.3) from $S_{4,4}$ to $S_{m,n}$, we see $S_{m,n}$ must be of the form (6.1), possibly divided by some factor of the HCF of $W_{m-2,n}$ and $W_{m-3,n}^2 W_{m-3,n-1} W_{m-3,n+1}$. However, we show below that $W_{i,j}$

is an irreducible polynomial in the U_k and V_k, so this HCF is unity, and $S_{m,n}$ is also of the form (6.1) as required.

To establish the irreducibility of $W_{m,n}$, we consider first the special number wall of a transcendental sequence $[V_k]$, i.e. $U_k = 1$ for all k. Notice that any factor of a homogeneous polynomial must also be homogeneous, since the product of two polynomials with minimum total degree a, c and maximum b, d resp. necessarily contains terms of degrees $a + c$ and $b + d$. Fixing say $n = m$, by (3.1)

$$S_{m,m} = \begin{vmatrix} V_m & \dots & V_{2m} \\ \vdots & \ddots & \vdots \\ V_0 & \dots & V_m \end{vmatrix}.$$

V_{2m} has cofactor $S_{m-1,m-1}$, which by assumption is irreducible. So if $S_{m,m}$ factorizes properly, it has a linear factor containing V_{2m}; and the other factor must equal $S_{m-1,m-1}$, which does not contain ${V_m}^m$. So their product does not contain ${V_m}^{m+1}$, and cannot be $S_{m,m}$: thus in the special number wall of a sequence of distinct transcendentals, $S_{m,m}$ and by translation $S_{m,n}$ is an irreducible polynomial.

Now consider the GSW. If $W_{m,n}$ factorizes properly, it has a factor containing no V_k elements (otherwise we could specialize to a factorization for the special wall above). By an easy induction using (3.6), $W_{m,n}$ contains just one term which is a multiple of ${V_n}^{m+1}$: specifically, $Z_{m,n}{V_n}^{m+1}/U_n^m$. So any factor can only be a monomial which (partially) cancels with the denominator as given above, and what remains of the numerator is irreducible. ■

A more refined induction ought to show that not even monomial cancellation can occur above; hence that the polynomial degrees and the form of $Z_{m,n}$ given in (6.1) are exact, and indeed that the total degree of $W_{m,n}$ in the U_k, V_k separately is uniformly $m(m-1)$, $m(m-1)+2$ resp. Moreover we conjecture that the sum of the absolute values of the coefficients of $W_{m,n}$ is $2^{m(m+1)/2}$. This last quantity — essentially the number of terms in the m-th row of a polynomial GSW — is uncomfortably large: for example, $W_{4,n}$ is a polynomial of about $30,000$ terms, each of degree 26.

A referee has made the point that we have inadvertently introduced not one but two generalizations here. Given sequences $[T_n], [S_n]$ over the ground domain, firstly we generate the 'numerical' GSW $S_{m,n}$ via recursion (5.1); secondly we substitute them for $[U_n], [V_n]$ in the formal GSW (6.1). [It is assumed both $[T_n], [S_n]$ everywhere nonzero, ensuring both that (3.8) holds initially — without which no (5.1)) — and that the denominators $Z_{m,n}$ are nonzero in (6.1).] Now, are the two walls equal? If we had an explicit expression for the GSW element, we might consider adapting the Frame Theorem proof to incorporate it. Failing that, we can at least observe that they are surely equal if either wall is everywhere nonzero, since algorithms (3.7) and (5.1) are then equivalent; and again, they are equal if $[T_n], [S_n]$ happen to be a pair of adjacent rows (or indeed columns) from some pukka SNW, by the existing Frame Theorem.

Now any given GSW element depends on only a finite subset of $[T_n], [S_n]$. We might therefore seek to show that every finite region of the GSW may be embedded in some SNW, generated by some sequence $[R_n]$ say (dependent on the region). [The region may be taken to be a (square) diamond, with base on the row $[T_n]$ and apices at some target element and its reflection in the base]. In specific instances, this embedding is straightforward to verify: the equations for $[R_n]$ turn out to be linear in $[T_n], [S_n]$, and it appears sufficient to consider $[R_n]$ of period at most thrice the diameter. However, a general proof is complicated by the fact that any fixed scheme of equations may be rendered singular by some zero within the region, in spite of the fact that in practice such zero-windows make a specific problem easier to solve.

We turn to another question posed by Propp, the statement and solution of which exemplify the geometric nature of the number wall. It concerns the extent to which the frame rules might be in some covert fashion *local*, in the sense that the value of an element is independent on those outside some bounded neighborhood. Specifically he asks: given arbitrarily large k, do there exist two distinct walls with k (or more, but only finitely many) consecutive rows in common? Such questions as what ground domain is specified, whether horizontal and/or vertical translations are to be regarded as differences in this context, and whether the wall is special, can be postponed; we shall see that the answer turns out to satisfy the most stringent of such conditions.

Consider an arbitrary relation J of order r with leading and trailing coefficients equal to unity, with $[S_n]$ satisfying $S_1 = \ldots = S_{r-1} = 0$ and $S_r = 1$ (the so-called *impulse response sequence* or IRS), and having

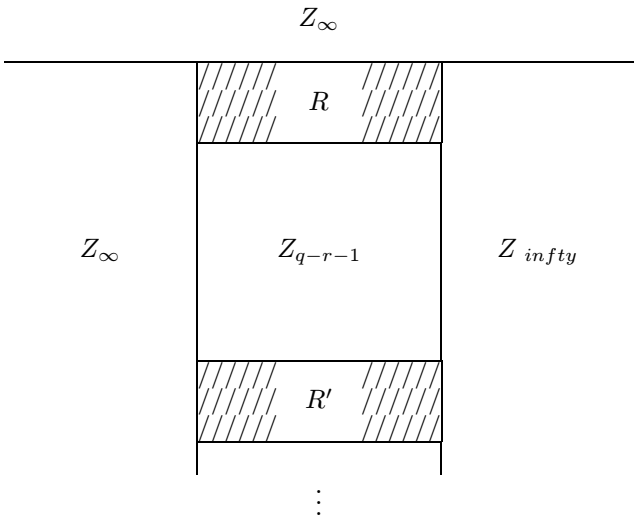
period q; then define

$$T_n \;=\; \begin{cases} S_n & \text{if } r \le n \le q; \\ 0 & \text{otherwise.} \end{cases}$$

Then the wall for T is easily seen to be of form diagrammed, where Z_g denotes a $g \times g$ window (with inner frame unity), R denotes the $(r+1) \times (q-r+1)$ rectangular region comprising one period of the wall for $[S_n]$ but excluding its initial Z_{r-1}, and R' denotes the reflection of R about a horizontal line. Now replace the original relation J by any other relation satisfying the same restrictions: all rows meeting the interior of R or R' will in general be altered, whereas those meeting the finite windows must remain the same. So the wall generated satisfies Propp's conditions with $k = q - r + 1$.

Incidentally, there is a sense in which the 'real' wall here is actually just the finite rectangle R; we make this manifest by repositioning the inner frames of the infinite windows, so that there are instead four half-infinite frames spiraling away in the same sense (as in the next example) from the corners of R, which is now isolated at the centre. The result is easily verified to be a GSW.

Diagram Generalized Wall



[For the remainder of this section we assume the ground domain is binary.] The simplest examples of these GSW's occur when R is itself a single $g \times g$ window, surrounded by four infinite windows. This is the special case $h = \infty$ of what one might call a 'bathroom wall': an offset tiling of windows of sizes $g+1$ and $h+1$ (note the increase in size resulting from the frame), where $0 \le g < h \le \infty$. Another important example, the case $g = 0, h = 1$ is the unique binary wall with minimum density $(1/5)$ of zeros; it consists of the pattern below, replicated on a tiling of squares.

```
0 1 1 1 1
1 1 0 1 1
1 1 1 1 0
1 0 1 1 1
1 1 1 0 1
```

Finally, an entertaining problem is suggested by the observation that there are binary GSW's with isolated rectangular regions, and also with isolated square windows: are there any with nontrivial isolated squares, i.e. possessing some interior structure? The answer is a little surprising: there is essentially just one, as follows. The relation

$$J \;=\; (\mathbf{E}+1)(\mathbf{E}^3+\mathbf{E}+1)^2 \;=\; \mathbf{E}^7+\mathbf{E}^6+\mathbf{E}^3+\mathbf{E}^2+\mathbf{E}+1,$$

has IRS period comprising a block of $r-1$ zeros followed by the coefficients of J itself (because $J(X)J(1/X) = X^r + X^{-r}$):

$$S_n \;=\; [\ldots, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 0, 0, 1, 1, \ldots],$$

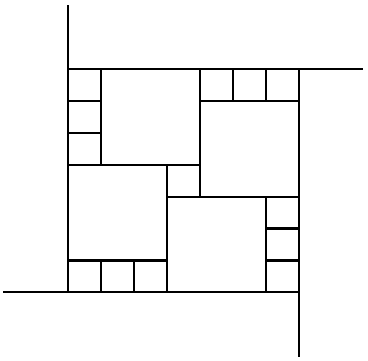
and $r = 7, q = 14$ in the earlier notation. The wall (illustrated below) of the modified sequence

$$T_n \;=\; [..., 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0, 0, 0, 0, ...],$$

manipulated as above, is essentially an isolated 8x8 square R which is not a 6×6 window; it has four symmetries generated by quarter-turns, and the only other solution is its reflection R'.

Diagram Isolated Square Wall

```
0 0 1 0 0 0 0 0 0 0 0 0
0 0 1 0 0 0 0 0 0 0 0 0
0 0 1 1 1 1 1 1 1 1 1 1
0 0 1 1 0 0 1 1 1 1 0 0
0 0 1 1 0 0 1 0 0 1 0 0
0 0 1 1 1 1 1 0 0 1 0 0
0 0 1 0 0 1 1 1 1 1 0 0
0 0 1 0 0 1 0 0 1 1 0 0
0 0 1 1 1 1 0 0 1 1 0 0
1 1 1 1 1 1 1 1 1 1 0 0
0 0 0 0 0 0 0 0 0 1 0 0
0 0 0 0 0 0 0 0 0 1 0 0
```



The uniqueness is a matter of constructing all binary polynomials with period twice their order, a straightforward exercise in finite field theory. As the diagram suggests, it can be regarded geometrically as a question of packing a square with smaller squares, with side-conditions equivalent to (5.5), which does not look too easy combinatorially!

7. Performance and the FSSP

For a number-wall of length and depth N, the complexity of a straightforward implementation of the number-wall algorithm as described above is easily seen to be of order N^2 space and N^3 time (assuming arithmetic operations to be of constant complexity); an extra factor of N arises in both requirements from the necessity to locate the frame of the current zero-window, which may itself be of size N. [The time could be improved simply by storing the origin and size of the window above for each element of the current row, at the cost of storing three rows of integers.]

It is possible to reduce the complexity to order N space and N^2 time, at least in the binary case, by 'hard-wiring' the algorithm as a *Cellular Finite-State Automaton* (C-A; see **Min67**). Briefly, the C-A stores the current row m of the wall, each cell n holding the value of a single binary determinant $S_{m,n}$ (in practice, two copies of the array are required, for old and new values of the state). The state is a 44-valued product comprising 2 bits for left and right-shifting buffers for the outer frames of the current zero-window, and 11 states for a slightly modified Firing-Squad Synchronization Problem machine (FSSP; see **Maz86**) to locate the South edge of the inner frame.

[It would take us too far afield to go into detail about the FSSP. Briefly, imagine a squad of identical soldiers, each equipped with his own gun and with a (synchronized) clock marking instants of time; between instants a soldier assumes any one of an initially determined set of states. At each instant the state of a soldier changes to a new value, completely determined by his own previous state and those of his two nearest neighbors. There are g soldiers in the line, but none of them knows the value of g. Initially, the whole squad is *Quiescent*; but at some random instant the leftmost soldier assumes the *Command* state. The problem is to train the squad identically so that at some instant ($2g - 1$ after the command is in general the minimum achievable) they will all for the first time simultaneously assume the *Firing* state.]

In the notation of the Frame Theorems (§4 figure), each cell picks up E from the North of the window, then shifts it rightward until it hits the East frame, where G is added in, after which $E+G$ is sent leftward. In the meantime F from the West is shifted rightward until the two collide on the South frame, where they are added to give H. The FSSP is started by commands in both North corners of the window simultaneously, so that it fires after g steps rather than $2g$; sadly, this means we cannot employ Mazoyer's beautiful asymmetric 6-state solution **Maz87**, although we could use Balzer's symmetric 8-state solution to reduce the state total to 40. The transition table for the binary C-A is only 85 Kbyte, and it is quite stunningly fast: a single 3-D array lookup for each determinant computed. Because of the localization of the data, on a massively parallel machine the complexity improves to order N time and space.

The C-A method can in principle be generalized to ground field $\mathbf{Z}_p$, but implementation seems to demand on the order of p^5 states, so is unlikely to be feasible for $p > 3$. A more practical approach is to retain the FSSP synchronization and the technique of shifting frame values right or left till they bounce off the frame of the window, but abandon any attempt to do arithmetic in the control structure: the values of the frame elements are simply shifted separately, each inner or outer edge having its own row of shifting buffers (A, E need two each, but their rightward buffers can be shared with B, F). The arithmetic for the South frame is all performed explicitly when the FSSP fires. This requires around ten one-dimensional arrays to implement, and retains the order N space and N^2 time complexity of the C-A, as well as its potential for parallelization.

The Frame algorithm (5.1), including the binary C-A variant, has been implemented in C-language as part of a sophisticated application program running on a Sun SPARC workstation, incorporating a graphical front-end allowing large segments (up to one million elements) of a number-wall to be viewed in color-coding. At a more modest level, there is available a pedagogic Maple implementation of most of the algorithms described here, designed for the examples shown here.

8. Interpolation and Vandermonde Matrices

In the next three sections we turn to a distinct but closely related problem, which receives surprisingly little attention in standard texts: the efficient computation of the explicit form of S_n for an LFSR sequence $[S_n]$ from its relation and/or from (a sufficiency of) its terms. The first two sections summarize and dilate upon standard material required for the third.

We denote by $\sigma_i(X_1, \ldots, X_r)$ the elementary symmetric function of degree i on r variables X_i, and recall the well-known

Lemma: The polynomial equation with roots $X = X_1, \ldots, X_r$

$$J(X) \;=\; \prod_k (X - X_k) \;=\; \sum_i J_i X^i \tag{8.1}$$

has coefficients given by $J_i = (-)^{r-i}\sigma_{r-i}((X_1, \ldots, X_r))$.

For development and analysis of algorithmic efficiency, we need to make the point that all the 'defective' symmetric functions $\sigma_i(\ldots, X_{\neq k}, \ldots)$ — that is, on $r-1$ variables excluding X_k — can be computed efficiently in order r^2 time by first employing and then reversing the usual inductive algorithm:

Algorithm: Initially for $i = 0$, $k = 0, 1, \ldots, r$ set $\sigma_0(X_1, \ldots, X_k) = 1$;
for $k = 0$, $i = 1, \ldots, r$ set $\sigma_i() = 0$;
for $k = 1, 2, \ldots, r$ set

$$\begin{aligned} \sigma_0(X_1, \ldots, X_k) &= 1, \\ \sigma_{i+1}(X_1, \ldots, X_k) &= \sigma_{i+1}(X_1, \ldots, X_{k-1}) + X_k \sigma_i(X_1, \ldots, X_{k-1}); \end{aligned} \tag{8.2}$$

then for $k = 1, 2, \ldots, r$ set

$$\begin{aligned} \sigma_0(\ldots, X_{\neq k}, \ldots) &= 1, \\ \sigma_{i+1}(\ldots, X_{\neq k}, \ldots) &= \sigma_{i+1}(X_1, \ldots, X_r) - X_k \sigma_i(\ldots, X_{\neq k}, \ldots). \end{aligned}$$

From now on we shall assume that the $[X_i]$ are *distinct*, that is either they are transcendental or $X_i \neq X_j$ for $1 \leq (i,j) \leq r$. We require some properties of the (fairly) well-known *Vandermonde* matrix M, defined by

Definition:

$$M_{ij} \;=\; (X_j)^i. \tag{8.3}$$

Its determinant is given by

Theorem:

$$|M_{ij}| \;=\; \prod_k \prod_{l<k} (X_k - X_l), \tag{8.4}$$

and its matrix inverse by $N \cdot M = I$ where

Theorem:

$$N_{ji} \;=\; \frac{(-)^{i-1}\sigma_{r-i}(\ldots, X_{\neq j}, \ldots)}{\prod_{k\neq j}(X_k - X_j)}. \tag{8.5}$$

Proof: As any undergraduate used to know, by subtracting column l from k, the determinant divides by $(X_k - X_l)$; and by inspecting the diagonal term, the remaining constant factor is unity. The inverse (hinted at darkly in **Knu81** §1.2.3 Ex. 40 and in **Ait62** §49) is more or less immediate by (8.1) with X_j replacing X and omitted from the roots:

$$\begin{aligned}(N \cdot M)_{ij} \;&=\; \sum_k N_{ik} M_{kj} \\ &=\; \frac{\sum_k (-)^{i-1}\sigma_{r-k}(\ldots, X_{\neq i}, \ldots)(X_j)^k}{\prod_{k\neq j}(X_k - X_j)} \\ &=\; \prod_{k\neq i}(X_k - X_j) / \prod_{k\neq j}(X_k - X_j) \;=\; I_{ij}\end{aligned}$$

where I_{ij} denotes the Kronecker delta. [The commutation $M \cdot N = I$ is considerably less obvious!] ■

By (8.5) we can explicitly solve the simultaneous linear equations $K \cdot M = S$ arising in fitting a linear combination of given exponentials, since $K = S \cdot N$:

Corollary:

$$S_i \;=\; \sum_j K_j {X_j}^i \tag{8.6}$$

if and only if

$$K_j \;=\; \frac{\sum_i S_i (-)^i \sigma_{r-i-1}(\ldots, X_{\neq j}, \ldots)}{\prod_{k\neq j}(X_k - X_j)}.$$

Returning to our illustration, suppose we have established as in §2 or §3 that $S = [0,0,0,1,\ldots]$ is an LFSR sequence with relation which turns out to factor as $J(\mathbf{E}) = (\mathbf{E}-7)(\mathbf{E}-5)(\mathbf{E}-3)(\mathbf{E}-1)$; so its roots are $[X_1, X_2, X_3, X_4] = [7,5,3,1]$ and the difference products $[(X_2 - X_1)(X_3 - X_1)(X_4 - X_1), \ldots] = [-48, +16, -16, +48]$. Computing the elementary and defective symmetric functions via (8.2) gives

$i\backslash k$	0	1	2	3	4
0	1	1	1	1	1
1	0	7	12	15	16
2	0	0	35	71	86
3	0	0	0	105	176
4	0	0	0	0	105

$i\backslash k$	1	2	3	4
0	1	1	1	1
1	9	11	13	15
2	23	31	47	71
3	15	21	35	105

.

Substituting all these into (8.6) gives $[K_1, K_2, K_3, K_4] \;=\; [+1, -3, +3, -1]/48$, whence the explicit form is

$$S_n \;=\; (1 \cdot 7^n - 3 \cdot 5^n + 3 \cdot 3^n - 1 \cdot 1^n)/48.$$

Finally, a surprising application of the Vandermonde determinant gives a formula for the number-wall of an LFSR sequence:

Theorem: If $S_n = \sum_i K_i {X_i}^n$, then in its number-wall $S_{m,n} = \sum_j B_j {Y_j}^{n-m}$, where $Y_j = \prod_k X_k$ is the product of any $m+1$ of the X_i, and

$$B_j \;=\; \prod_k K_k \cdot \prod_k \prod_{l \neq k} (X_k - X_l). \tag{8.7}$$

Here j indexes subsets of size $m+1$ from $\{1, \ldots, r\}$, the indices k, l being restricted to this j-th subset.

Proof: Express the $m = r-1$ case as product of two Vandermonde determinants:

$$S_{m,n} \;=\; |S_{n+i-j}| \;=\; \Big|\sum_k K_k {X_k}^{n+i-j}\Big| = |K_j {X_j}^i| \;\cdot\; |{X_i}^{n-j}|.$$

For $0 \leq m \leq r-1$ every term of the expanded determinant defines a unique subset of $m+1$ from r; collecting together all the terms with the same subset, we see that we must sum the VDM product over all such subsets. [This is best worked through on a small example: the sign of the result requires care.] ■

We shall later require an explicit formula for the number-wall for the binomial coefficients along the diagonals of the Pascal triangle, discussed in greater depth in the next section (9.4):

Theorem: The number-wall for $S_n = \binom{n}{r-1}$ is given by

$$S_{m,n} \;=\; \begin{cases} \displaystyle\prod_{k=0}^{k=m} \binom{n-k}{r-1-m} \Big/ \binom{r-1-m+k}{r-1-m} & \text{if } -1 \leq m \leq r-1, \\ \\ 0 & \text{otherwise.} \end{cases} \tag{8.8}$$

Proof: Assume for the moment that $S_{m,n}$ is *defined* by the above expression. Evidently $S_{-1,n} = 1$ and $S_{0,n} = \binom{n}{r-1}$ as required. If we ignore the sole $r-2 \;\times\; r-2$ zero-window at the origin (which turns out to give no trouble), we need only show that (3.6) is satisfied to clinch the result.

For $-1 \leq m \leq r-1$ the expression may be recast, more explicitly if less elegantly, as

$$S_{m,n} \;=\; \prod_{k=0}^{k=r-1} \Big(\frac{n-k}{k+1}\Big)^{\min(k+1,\; r-1-k,\; m+1,\; r-1-m)}.$$

By somewhat tedious comparison of the k-th exponents in pairs of elements of this form, it can be shown that, for $0 \leq m < r/2 - 1$ at least,

$$\begin{aligned} S_{m-1,n}/S_{m,n} &= (r-1-m)\ldots(m+1)/(n-m)...(n-r+m+2), \\ S_{m+1,n}/S_{m,n} &= (n-m-1)\ldots(n-r+m+3)/(r-2-m)...(m+2), \\ S_{m,n-1}/S_{m,n} &= (n-r+m+1)\ldots(n-r+1)/(n)...(n-r), \\ S_{m,n+1}/S_{m,n} &= (n+1)\ldots(n-r+1)/(n-r+m+2)...(n-r+2); \end{aligned}$$

whence easily

$$\begin{aligned} S_{m-1,n}S_{m+1,n}/S_{m,n}^2 &= (m+1)(r-m-1)/(n-m)(n-r+m+2), \\ S_{m,n-1}S_{m,n+1}/S_{m,n}^2 &= (n-r+1)(n+1)/(n-m)(n-r+m+2); \end{aligned}$$

so

$$(S_{m-1,n}S_{m+1,n} \;+\; S_{m,n-1}S_{m,n+1})/S_{m,n}^2 \;=\; 1,$$

and (3.6) is satisfied.

For $r/2-1 \le m < r$, notice that the recast expression is symmetric under $m \to r-2-m$; therefore the entire wall is symmetric about its horizontal midline, and (3.6), also symmetric, is satisfied here too. ■

We are (almost) in a position to characterize the rows of an LFSR wall:

Corollary: If $[S_n]$ is an LFSR sequence of order r, then for each m $[S_{m,n}]$ is an LFSR sequence of order at least $\max(0, 1+(m+1)(r-1-m))$ and at most $\binom{r}{m+1}$. (8.9)

Proof: the upper bound results from assuming all the Y_j distinct in (8.7), and applying (2.2) conversely; the lower bound from assuming that the Y_j coincide (say with unity), then observing that (3.10) in the nonzero region is the product of $m+1$ polynomials of degree $r-1-m$ in n; by expanding the Toeplitz determinant, the addition of lower-degree terms to $K(n)$ and the geometric factor $Y^n = X^{mn}$ make no difference to the order.

Any coincidence between two Y_j corresponding to distinct choices of X_i in (8.7) serves merely to reduce the order of the row by the smaller of their contributions. The general case of multiple roots X_i in the relation itself is more involved: it would divert us too far to attempt to analyse it here, and we content ourselves with a plausible assertion: the order of any row of the wall of an LFSR sequence, satisfying a given relation with possibly multiple roots, cannot increase if the relation is massaged so as to cause coincidences additional to those already present. ■

The computation of the actual relation satisfied by a given row of the wall generated by a given relation is an interesting exercise in symmetric functions, which again shall not detain us here.

9. Difference Tables

Extrapolation of a sequence is a common requirement, arising in numerical computation, recreational problems, critical-point estimation and cryptographic contexts. The familiar *Difference Table*, see for example **Fro85** §14, is defined by the recursion

Definition:

$$\begin{aligned} T_{0,n} \;&=\; S_n; \\ T_{m,n} \;&=\; (\mathbf{E}-1)^m S_n \;=\; \boldsymbol{\Delta}^m S_n \;=\; T_{m-1,n+1} \;-\; T_{m-1,n} \quad \text{for } m>0; \end{aligned} \tag{9.1}$$

it has the property that $T_{m,n}$ vanishes for all $m > r$ just when S_n equals a polynomial in n of degree r. By extending the region of zeros with n then reversing the direction of the recursion with m, we can efficiently extrapolate such a sequence to greater n. Further, the explicit form of the polynomial may be recovered via Newton's forward difference formula, subject to the caveat below:

Theorem: If the polynomial sequence $[S_n]$ has difference table $[T_{i,j}]$ then

$$S_n \;=\; \sum_i T_{i,0}\binom{n}{i}. \tag{9.2}$$

Similarly if $[S_n]$ is LFSR of order r, then by (3.3) its wall vanishes for $m > r$. Since by (2.2) a polynomial sequence of degree r is a (special case of a) LFSR sequence of degree $r+1$, the same use may be made of the number-wall to give a generalized extrapolation algorithm, albeit requiring an extra term and a rather more complicated computation of the explicit form. This application is described in an elementary fashion in **Slo95** §1 and **Con96** §3, employing an ingenious notation unhappily compromised by a clutch of demoralizing misprints.

A difficulty with interpreting (2.2) for finite ground characteristic p is that the Little Fermat Theorem $n^p = n \pmod p$ effectively prevents the degree of 'naïve' polynomials based on powers n^j from exceeding $p-1$. A straightforward solution to the difficulty is suggested by (9.2): to base our polynomials on binomial coefficients $\binom{n}{j}$ instead. This falls over in a similar fashion if we attempt the usual

Definition:

$$\binom{n}{j} \;=\; \prod_{0\le i<j} (n-i)/(i+1). \tag{9.3}$$

But as it happens, the computation of binomial coefficients for characteristic p is the stuff of numerous recreational articles and student projects. Write $l = p^k$. Decomposing the difference table for $\binom{n}{l-1}$ (which is just the IRS of $\mathbf{E}^l - 1$) into p^2 blocks of edge l/p, observing that each block is a multiple of the table for $\binom{n}{p^{l/p}-1}$, and that the blocks themselves satisfy the Pascal triangle recursion (2.3), by induction on k we get the pretty result (ascribed to Lucas in the survey article **Gra96**):

Theorem:

$$\binom{n}{m} \;\equiv\; \begin{cases} \prod_i \binom{n_i}{m_i} \pmod p & \text{if } n \ge 0,\ m \ge 0, \\ (-)^{-n+m-1}\binom{-n+m-1}{m} & \text{if } n < 0,\ m \ge 0, \\ 0 & \text{if } m < 0, \end{cases} \tag{9.4}$$

where n_i and m_i denote the digits of n and m written to base p; the later parts of the right-hand side are elementary.

This costs order $\log n$ time; the terms on the right-hand side can be computed easily via (2.3) as a table of p^2 entries. It also demonstrates that the binomial coefficient is mathematically defined within the domain, allowing us to apply all the usual machinery of difference calculus within the domain as well. A simple illustration of the situation is $[S_n] = [0,0,0,1,0,0,0,1,\ldots]$ for $n = 0,1,2,\ldots$, with relation $S_{n+4} - S_n = 0$ whose quadruple root over the binary domain is $X = 1$. By LFT, no naïve binary polynomial can have period > 2; but as required

$$[\binom{n}{3}] \;=\; [0,0,0,1,4,10,20,35,...] \;\equiv\; [S_n] \pmod 2$$

Sequences with period a power of the characteristic have a useful property:

Lemma: If $[S_n]$ has period $l = p^k$ then

$$(\mathbf{E}^l - 1)[S_n] \;=\; (\mathbf{E} - 1)^l [S_n] \;=\; [O_n], \tag{9.6}$$

since $\binom{l}{j} = 0$ except when $j = 0, l$, using (9.4). So by (2.2), S_n is a polynomial (in the binomial sense) of degree r, where $l/p < r \le l$ (unless the period is l/p or smaller). By (9.1), we can employ a difference table rather than a number wall to compute its order. Moreover, by (9.6) in reverse, we can difference p^i times in the same time as differencing once: so initially setting $i = k$ and progressively reducing i as the period of the current row m decreases, we can compute the order in kp rows instead of l, giving about order lp time.

We illustrate the method with a Maple program:

Algorithm:

```
orderSpk := proc (S, p, k)
local T, dT, m, j, l;
l := p^k; m := 0; T := S;
while l > 1 do
dT := [seq((T[j+l/p mod l +1] - T[j+1]) mod p, j = 0..l-1)];
if sum(dT[j+1], j = 0..l-1) = 0
then l := l/p else m := m + l/p; T := dT fi od;
m + min(1, T[1]) end;
```

(9.7)

An application of the preceding theory occurs in the study of deBruijn sequences, which are defined traditionally over a finite set of size q as k-distributed (every k-tuple occurring with the same frequency), and having minimum period q^k. In the case where the set is actually a finite field, the extra structure allows us to define and compute the order of the sequence *qua* LFSR sequence over that domain; now the method outline above can be employed to substantially reduce the time (by the traditional factor of $l/\log l$). In an investigation such as **Bla96**, **Cha82** where the computation of the order is the inner loop of a lengthy combinatorial search, such a reduction is crucial. [In fact **Bla96** employed a more involved formulation of polynomials, basing the computation of the order on a modified Fast Fourier Transform.]

As a numerical example, we compute the order of the deBruijn sequence with $q = p = 2$, $k = 5$ and order $r = 21$ over $\mathbf{F}_2$ (but 25 over $\mathbf{Z}$). [It is essentially unique, modulo reflection and (independent) complementation of the first or last half.] T denotes the current m-th difference of S, l the currently detected period; when the l/p-th difference of T would be zero, the period is reduced instead.

l	m	$dT = 0$?	T
32	0	N	11111001000001010011101011000110
32	16	Y	11000011110000111100001111000011
16	16	Y	1100001111000011
8	16	N	1100001111000011
8	20	Y	11111111
4	20	Y	1111
2	20	Y	11
1	20	N	1
0	21		

For the deBruijn sequence with $q = p = 2$, $k = 4$ at the end of §6, we find from the full difference table (not shown) that $T_{i,0} = 1$ only for $i = 0, 4, 10, 11$; therefore an explicit 'binomial' expression for the n-th term is

$$S_n \;=\; 1 + \binom{n}{4} + \binom{n}{10} + \binom{n}{11}.$$

Finally, we touch on a rather curious interaction between difference tables and number walls, which comes to light when we try to establish exactly what effect a simple transformation of the sequence has on its wall. For instance, a little thought suggests that term-by-term addition of a low-order LFSR sequence to $[S_n]$ will only have a (literally) marginal effect on any large windows, causing their frames to shift by at most the order added. However, our only explicit progress in this direction is the

Theorem: The wall for $1 + S_n$ is just the wall for S_n itself added to the wall for $-\mathbf{\Delta}^2 S_{n-1}$ shifted down by one row. That is,

$$\text{Let } R_n \;=\; 1 + S_n, \quad T_n \;=\; -S_{n+1} + 2.S_n - S_{n-1}; \quad \text{then } R_{m,n} = S_{m,n} + T_{m-1,n} \tag{9.8}$$

Proof: Rather than attempt a formal but notationally impenetrable proof for the general case, we illustrate it by the case $m = n = 3$. Starting from the determinant definition (3.1), $R_{33} \;=$

$$\begin{vmatrix} 1+S_3 & 1+S_4 & 1+S_5 & 1+S_6 \\ 1+S_2 & 1+S_3 & 1+S_4 & 1+S_5 \\ 1+S_1 & 1+S_2 & 1+S_3 & 1+S_4 \\ 1+S_0 & 1+S_1 & 1+S_2 & 1+S_3 \end{vmatrix};$$

expanding each by column in turn, and noticing that any determinant with two or more equal columns of ones must be zero, this becomes

$$S_{33} + \begin{vmatrix} 1 & 1+S_4 & 1+S_5 & 1+S_6 \\ 1 & 1+S_3 & 1+S_4 & 1+S_5 \\ 1 & 1+S_2 & 1+S_3 & 1+S_4 \\ 1 & 1+S_1 & 1+S_2 & 1+S_3 \end{vmatrix} + \begin{vmatrix} 1+S_3 & 1 & 1+S_5 & 1+S_6 \\ 1+S_2 & 1 & 1+S_4 & 1+S_5 \\ 1+S_1 & 1 & 1+S_3 & 1+S_4 \\ 1+S_0 & 1 & 1+S_2 & 1+S_3 \end{vmatrix} + \ldots + \begin{vmatrix} 1+S_3 & 1+S_4 & 1+S_5 & 1 \\ 1+S_2 & 1+S_3 & 1+S_4 & 1 \\ 1+S_1 & 1+S_2 & 1+S_3 & 1 \\ 1+S_0 & 1+S_1 & 1+S_2 & 1 \end{vmatrix};$$

then subtracting row $i+1$ from row i for $i = 1, \ldots, m$ and pivoting on the bottom one for each determinant,

$$S_{33} \; - \; \begin{vmatrix} \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_4 & \boldsymbol{\Delta} S_5 \\ \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 \end{vmatrix} + \begin{vmatrix} \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_4 & \boldsymbol{\Delta} S_5 \\ \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta} S_0 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 \end{vmatrix} - \begin{vmatrix} \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_5 \\ \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta} S_0 & \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_3 \end{vmatrix} + \begin{vmatrix} \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 \\ \boldsymbol{\Delta} S_0 & \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_2 \end{vmatrix}.$$

The first two determinants have identical columns except the leftmost, say $[F_i]$ in the first and $[G_i]$ in the second; we contract them into a single determinant, with first column $[F_i - G_i]$. Each remaining determinant contains both columns; we subtract $[F_i]$ from $[G_i]$ and change the sign, giving

$$S_{33} \; - \; \begin{vmatrix} \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta} S_4 & \boldsymbol{\Delta} S_5 \\ \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta}^2 S_0 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 \end{vmatrix} + \begin{vmatrix} \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_5 \\ \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta}^2 S_0 & \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_3 \end{vmatrix} - \begin{vmatrix} \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta} S_2 & \boldsymbol{\Delta} S_3 \\ \boldsymbol{\Delta}^2 S_0 & \boldsymbol{\Delta} S_1 & \boldsymbol{\Delta} S_2 \end{vmatrix}.$$

We are now in a similar situation, except that $[F_i]$ and $[G_i]$ are now the column two of the first two determinants. Repeating the previous operation,

$$S_{33} \; - \; \begin{vmatrix} \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta}^2 S_3 & \boldsymbol{\Delta} S_5 \\ \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta}^2 S_0 & \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta} S_3 \end{vmatrix} + \begin{vmatrix} \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta}^2 S_3 & \boldsymbol{\Delta} S_4 \\ \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta} S_3 \\ \boldsymbol{\Delta}^2 S_0 & \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta} S_2 \end{vmatrix}.$$

Finally after $m-2$ iterations, we are left with the required expression

$$S_{33} \; - \; \begin{vmatrix} \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta}^2 S_3 & \boldsymbol{\Delta}^2 S_4 \\ \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta}^2 S_2 & \boldsymbol{\Delta}^2 S_3 \\ \boldsymbol{\Delta}^2 S_0 & \boldsymbol{\Delta}^2 S_1 & \boldsymbol{\Delta}^2 S_2 \end{vmatrix} \; = \; S_{33} \; + T_{23}. \; \blacksquare$$

Hence by (3.1) we easily get the wall for $R_n = A + B.S_n$: with S_n and T_n as in (9.8), $R_{m,n} = B^{m+1} S_{m,n} + A^{m+1} T_{m-1,n}$. Notice also that the wall for $R_n = C^n S_n$ is $R_{m,n} = C^{(m+1)n} S_{m,n}$.

10. Explicit Form of an LFSR Sequence

We shall briefly discuss efficient methods for computing the roots X_i and coefficients K_i in the explicit form (2.2) for S_n. From now on we mostly restrict ourselves to the integer domain $\mathbf{Z}$ embedded within the complex numbers $\mathbf{C}$; still, much of what we say is interpretable in a more general context of a continuous algebraic completion of the ground domain. 'Combinatorial explosion' (exponential numerical growth) is a constant hazard in integer algebraic computation, and it may sometimes be worth remembering a spectacular trick: where there is good reason to suppose that, for instance, the coefficients of the relation of a given sequence are going to be small, then the Berlekamp-Massey algorithm can perfectly well be applied modulo a smallish prime instead; or even modulo several very small primes and, the result being reconstructed by the Chinese Remainder Theorem as in **Dav88** §4.

In order to calculate the relation for a given sequence, or the explicit coefficients for given roots, it is possible to set up simultaneous linear equations and solve them in order r^3 time. This approach becomes cumbersome by hand for $r > 4$, whereas (by contrast) the coefficient equations are rapidly solvable explicitly. A more practical approach is to compute the relation polynomial $J(X)$ using Berlekamp-Massey (12.1), which costs order r^2 time; then extract its roots X_i formally, or more likely approximate them numerically using one of the various available methods surveyed for instance in **Hen74** §6.9. With the X_i to hand, assuming them to be distinct we can immediately apply (8.6) to find the K_i, again in order r^2 time.

We have avoided the general case of multiple roots in the present treatment; in this direction we currently have only partial results. In the first place, multiple roots of polynomials are numerically ill-conditioned, so that it's quite likely that we never get to the point of trying to find the coefficients at all. If we do, and it happens that all the roots coincide, then S_n is a known exponential times a polynomial, and the latter is found by (9.2). For the general confluent case, the analogue of the Vandermonde determinant $|M|$ and the explicit form of $S_{m,n}$ can be evaluated; but the formal inversion of the matrix M looks rather gruesome, and will be postponed for the present.

An alternative approach bypasses the relation and Vandermonde inverse altogether, approximating roots and coefficients directly via quotients of number wall elements. The point here is that if $|X_1| > |X_2| > \ldots$, then for large n, $Y_1^n = (X_1 X_2 \ldots X_{m+1})^n$ dominates in (8.7). So it becomes possible to divide out unwanted factors from this term in the explicit representation, leaving only the desired quantities together with error terms which decrease exponentially with n — in fact, as $|X_m/X_{m+1}|^{-n}$. Of course, n can be made arbitrarily large simply by extrapolating from the bottom (zero) row of the number-wall upwards. In this way, we approximate first the $[X_i]$, then the $[K_i]$:

Corollary: If the roots X_i of the relation $J(\mathbf{E}) = 0$ for $[S_n]$ have distinct magnitudes (so are real), then

$$(S_{m,n+1}/S_{m-1,n+1})/(S_{m,n}/S_{m-1,n}) \to X_m \tag{10.1}$$

in order of magnitude descending as m increases.

Corollary: With X_i as above,

$$S_{m,n}/S_{m-1,n} \to L_m K_m {X_m}^n \tag{10.2}$$

where

$$L_m \;=\; \prod_{k<m} (1 - X_m/X_k)(1 - X_k/X_m)$$

depends only on m and the X_i.

Notice that the relative error in K_m is n times larger than that in X_m, because of the factor ${X_m}^n$; as a result, the direct method (8.6) gives more accurate results.

In the case of equal magnitudes, the ratios on the relevant rows fail to converge, but it is still possible to approximate the polynomial isolating the set of troublesome roots:

Corollary: With X_i as above, save for a pair of roots X_m, X_{m+1} of equal magnitude, these satisfy the approximate quadratic

$$(S_{m,n}/S_{m-1,n})X^2 \;-\; (S_{m,n+1}/S_{m-1,n+1})X \;+\; (S_{m,n+2}/S_{m-1,n+2}) \;=\; 0; \tag{10.3}$$

the extension to many roots should be obvious.

Finally, from the X_i the relation components J_i can be approximately recovered as elementary symmetric functions of the roots, via (8.1), (8.2).

Returning to our illustration, we extrapolate the sequence and its wall out to $n = 49$ by reversing algorithm (3.7) (assuming that any zeros have been left behind) using floating-point fixed-precision arithmetic, and apply (10.1), (10.2), (8.1), to get the following approximations:

m	0	1	2	3	4
$S_{m-1,n-1}$	1	$.7646532757^{39}$	$.1940424956^{71}$	$.1965470321^{92}$	$.8985007667^{91}$
$S_{m-1,n-2}$	1	$.5352573381^{40}$	$.6791487340^{72}$	$.2063743832^{94}$	$.9434258044^{93}$
X_m		7.000000590	4.999999574	2.999999995	1.000000002
L_m		1.000000000	−.1142858304	.2031745788	−21.94285652
K_m		.02083324281	−.06250021019	.06250000887	−.02083333304
J_m	1	16.00000016	86.00000058	176.0000002	104.9999999

.

Here superscript k denotes multiplication by 10^k. Comparison with the exact answers found earlier shows that we have solved all three problems quite successfully and, as it were, under one roof. The worst relative error is $\frac{1}{2}10^{-5}$ in K_1; this could be reduced by a factor of ten, by employing (8.6) instead.

Finally, we should mention fast techniques for computing a distant element S_n of an LFSR which avoid solving explicitly for the general term or computing every intermediate element. In the case that the recurrence $J(\mathbf{E})$ is available, we can use J.C.P.Miller's method: evaluate $\mathbf{E}^n$ mod $J(\mathbf{E})$ as a polynomial of

degree r in $\mathbf{E}$, using the standard 'divide-and-conquer' algorithm for exponentiation in time of order $\log n$, then $S_n = \mathbf{E}^n S_0$ gives S_n in terms of $S_0, \ldots S_{r-1}$. If $S_0, \ldots S_{2r-1}$ is available but not $J(\mathbf{E})$, we can progress by extending S_j to $j = 4r$ (reversing the wall as above), starting a new wall based on $2r$ alternate terms S_{2j} or S_{2j+1} (depending on whether n is even or odd), then iterating and shifting according to the binary digits of n as for exponentiation. When working to fixed precision, numerical instability is a potential complication.

11. Padé Tables

The *Padé Table* of a function $F(Y)$ of one variable Y is essentially the array $R_{i,j} = P_{i,j}/Q_{i,j}$ of rational functions, with numerator and denominator polynomials of degree j and i resp., whose FLS agree with that of F in their first $i+j+1$ coefficients. [As earlier, there is no need to involve notions of convergence at this point.] We shall assume for simplicity that F is defined by a series with no negative powers of Y, and with constant coefficient unity.

There is a strong connection between linear recurrence relations and Padé approximation, resulting from the fact that (by simple algebra) the generating function for any right-infinite LFSR sequence $[S_n]$ is a rational function $P(Y)/Q(Y)$, where $Q(1/\mathbf{E})$ is a linear relation satisfied by $[S_n]$; we shall use the variable $Y \to 1/\mathbf{E}$ rather than $X \to \mathbf{E}$ to emphasize that the polynomial must be reversed. Older algorithms for computing (entries of) the Padé Table, as mentioned in the readable but casual compendium **Bak75** or detailed in the extensive survey **Wyn60**, break down when the table fails to be 'normal', that is when the function mimics a rational function over the initial portion of its series: the difficulty is essentially that of circumnavigating zero windows in the number wall, and can be overcome by the straightforward though leisurely method subsequently described here.

If $P(Y) = 1$, the sequence generated is the *Impulse Response Sequence* $[S_n]$ of $Q(1/\mathbf{E})$ commencing $[0, 0, ..., 0, 1, ...]$; the initial $r-1$ zeros will be consigned to the region $n < 0$ for now, the unity occupying $n = 0$. In practice, the entire left-hand halves of the number walls we consider here are zero (for $m \neq -1$ and $n < 0$), with $S_{-1,n} = S_{m,0} = 1$; the situation suggests that there might be an interesting connection between the two sequences $[S_n] = [S_{0,n}]$ and $[T_m] = [S_{m,1}]$, and so it transpires:

Algorithm: Let $F(Y) = \sum_n S_n Y^n$ and $1/F(Y) = \sum_n T_n Y^n$. Then $T_n = (-)^{n+1} S_{n,1}$ where $[S_{m,n}]$ is the number wall for $[S_n]$, and vice-versa. (11.1)

Proof: Elementary theory of determinants, applied to the definition (3.1) of $S_{m,n}$ (here nearly triangular) and convolution product of the series for F and $1/F$. ■

At order (N^2) time this algorithm for $1/F$ is more efficient than simple-minded approaches to series division, but no more so than standard methods such as **Knu81** §4.7.

Now let $F(Y) = \sum_n S_n Y^n$, where $S_n = 0$ for $n < 0$, and $S_0 = 1$. By inspecting the reasoning behind (3.4) a little more closely, it can be seen that $Q_{i,j} = C \times U_{i-1,j-1}$; where essentially as earlier $U_n(Y) = S_n - S_{n+1}Y$, and C lies in the ground domain and depends on i, j. Also, since the Padé table for $1/F(Y) = \sum_n T_n Y^n$ is simply $Q_{j,i}/P_{j,i}$, we have similarly $P_{i,j} = D \times V_{j-1,i-1}$, where $V_n(Y) = T_{n+1}Y - T_n$. The ratio D/C turns out to be a sign change $(-)^{ij}$; so finally

Algorithm: The Padé table entries for $F(Y) = \sum_n S_n Y^n$ are given by

$$R_{i,j} = (-)^{ij} V_{j-1,i-1}/U_{i-1,j-1}$$

where $U_{m,n}$ and $V_{m,n}$ are the number walls for

$$U_n(Y) = S_{n+1}Y - S_n \qquad \text{and} \qquad V_n(Y) = T_{n+1}Y - T_n, \tag{11.2}$$

and

$$T_n = (-)^{n+1} S_{n,1}$$

where $S_{m,n}$ is the number wall for S_n.

Note the transposition of subscripts and of offsets. [In the Padé Table literature, such polynomial number walls — with variant sign and origin — go by the name of *C-tables* or some similar term.]

An alternative approach to computing the numerators utilizes the observation that the $P_{0,j}$ are just the partial sums $W_n(Y)$ of the series, so it's reasonable to guess that the $P_{i,j}$ might be related to its wall $W_{m,n}$. As before there is an adjustment required [effectively because we would prefer to initialize $W_{-1,n} = Y^n$], and we find

Algorithm: The Padé table entries for $F(Y) \;=\; \sum_n S_n Y^n$ are given by

$$R_{i,j} \;=\; (-)^i Y^{-ij} W_{i,j} / U_{i-1,j-1} \tag{11.3}$$

where $U_{m,n}$ and $W_{m,n}$ are the number walls for

$$U_n(Y) \;=\; S_{n+1}Y - S_n \qquad \text{and} \qquad W_n(Y) \;=\; \sum S_n Y^k.$$

Though less elegant, this variation avoids the reciprocal function altogether, and is (somewhat) quicker when only a few rows of the table are required.

The expressions for $P_{i,j}$ and $Q_{i,j}$ essentially as Toeplitz determinants in U_n and W_n are ascribed to Jacobi **Bak75** (3.44); the resulting Sylvester identity (3.6) between five adjacent numerators or denominators is credited to Frobenius **Bak75** (3.30).

Both these algorithms, like (3.4) on which they are based, take order n^4 time (if elementary polynomial multiplication is employed), which for an individual approximant is slow compared to established methods; their performance improves when used to compute numerical values of Pade approximants directly, without first finding the polynomials. Even so, they are somewhat faster than the algorithm based on an elegant identity due to Wynn

$$1/(R_{i+1,j} - R_{i,j}) \;+\; 1/(R_{i-1,j} - R_{i,j}) \;=\; 1/(R_{i,j+1} - R_{i,j}) \;+\; 1/(R_{i,j-1} - R_{i,j})$$

(proved in **Wyn66** or **Gra72**), recommended by several authors, which can only cope with normal tables. Where the table fails to be normal, a 'Padé Block' (corresponding to a zero window in the wall for $[S_n]$), as generated by our algorithms, has identical approximants along its North and West edges with 0/0 elsewhere; strictly, that same approximant is valid throughout the NW half and on the diagonal, though none is customarily defined in the SE half.

Another topic closely interwoven with both Padé tables and LFSR sequences is that of continued fractions; see **Gil78** or **Bak75** §4 for a leisurely introduction.

12. Applications and Related Algorithms

The *Linear Complexity Profile* (LCP) is the traditional device for exploring the extent to which a sequence is piecewise definable by linear relations. It is defined as the sequence of orders of minimal linear recurrences satisfied by the finite segments $[S_0, \ldots, S_n]$ for $n = 0, 1, 2, \ldots$, a *recurrence* being a semi-proper (as it were) relation, having leading coefficient unity. [This restriction is partly justified by the consideration that the recurrence might be required for computing the sequence; more importantly, it avoids the unpleasant prospect of auxiliary polynomials with leading zeros. The distinction explains the confusing phenomenon of minimal recurrences whose order substantially exceeds half of their span.]

The connection between LCP notation and the number wall is discussed in the explanatory paper **Ste92**: broadly, the LCP (as it were) 'tracks' a zig-zag path along an adjacent pair of diagonals across the number wall, normally increasing by unity every two steps, but suffering a 'pause' as it traverses a window, punctuated by a 'jump' as the it crosses the counter-diagonal. (12.1) and (3.4) are not in practice very suitable for computing shifted LCPs, and the discussion in **Ste92** concluded that the most efficient method is in fact to compute the number wall first, then deduce the LCP from it (slightly tricky on account of the asymmetry mentioned above).

Much work has been done on the theory of LCPs, often using generating functions: see for example the references to Niederreiter. However, the technique is hampered by the difficulty of incorporating one-dimensional LCPs based on fixed origins into a properly two-dimensional representation of all *shifted* LCPs. Furthermore, where the domain is of finite characteristic, linear complexity is represented more compactly by

determinant than by LFSR order. We consider that the availability of an efficient algorithm for the number wall, together with the geometric viewpoint that it encourages, should cause it to supplant the LCP: geometric ideas play a particularly prominent role in linear complexity over $\mathbf{F}_p$ for $p = 2, 3$, see **Lun00**. The binary case is of practical importance since modified LFSR's are often employed as pseudo-random bit-stream generators for use in Monte-Carlo numerical methods, simulations and particularly stream ciphers: the frame recursion offers improved efficiency in testing such generators for *cryptographic insecurity*, expressed as exceptionally large zero-windows.

An attractive algorithm for extracting numerical approximations to the roots of a polynomial (as well as a number of related tasks such as eigenvalues of a matrix) is a modification of the number-wall known as the *QD method* of Rutishauser, described in detail in **Hen74** §7.6. Based on (8.1), this scheme computes the ratios directly on even rows, using odd rows for book-keeping: the elementary recursion (3.7) suffices for this purpose, the ground domain being the real numbers — where in numerical computation exact zeros are improbable — and in any case, he is able to choose the initial elements of his LFSR sequence so that no zeros can occur. [The convergence is only linear in n, but could in principle be accelerated, possibly using the techniques mentioned at the end of §10.]

Apparently Rutishauser himself had already considered the possibility of making the QD scheme continuous, that is interpolating between the rows and columns in the same way that discrete difference equations are interpolated into continuous differential equations. This topic seems to have only recently been much explored, under the heading of *Toda flows*: surveys are reported in **Fay94**, **Pap94**, for which I am indebted to Bill Dubuque.

We now summarize the *Berlekamp-Massey* algorithm for constructing the minimal relation generating a given LFSR sequence in order r^2 time:

Algorithm: The minimal relation spanning $S_0, \ldots, S_{2r-1}, \ldots$ is $J(\mathbf{E}) \equiv \mathbf{E}^r U_{2r}(1/\mathbf{E})$, where: Initially construct the generating function $T = \sum_n S_n Y^n$ of $[S_n]$ where Y is transcendental, for $0 \le n < 2r$ or further, and set

$$U_0 = 1, \quad V_0 = Y, \quad k_0 = 0;$$

then for $i = 1, 2, \ldots, 2r, \ldots$ iterate

$$\begin{aligned} W_i &\leftarrow \text{coefficient of } Y^{i-1} \text{ in } U_{i-1}T; \\ U_i &\leftarrow U_{i-1} - V_{i-1}W_i; \\ V_i &\leftarrow \begin{cases} U_{i-1}Y/W_i & \text{if } W_i \neq 0 \text{ and } k_i \ge 0, \\ V_{i-1}Y & \text{otherwise;} \end{cases} \\ k_i &\leftarrow \begin{cases} -k_i & \text{if } W_i \neq 0 \text{ and } k_i \ge 0, \\ k_i + 1 & \text{otherwise.} \end{cases} \end{aligned} \tag{12.1}$$

Used in 'exploratory' mode (where the order r is not known in advance), the algorithm generates $U_i = U_{2r}$ for $i \ge 2r$.

Proof: For this we refer the reader to **Lid86** §6.6, contenting ourselves with a few incidental observations. The variable Y corresponds to a backward shift $1/\mathbf{E}$ rather than forward, in order to avoid difficulties with leading zero coefficients in the polynomial arithmetic. At the i-th iteration, the result of evaluating the relation (corresponding to the reverse of) U_{i-1} for $\ldots, S_{i-1}$ is just W_i; there is no need to compute the entire polynomial product $U_{i-1}(Y)T(Y)$. Notice that intermediate U_i are not in general guaranteed to correspond to the minimal relations spanning $S_0, \ldots, S_{i-1}$. ■

The cost of computing a single relation is order r^2 time, a considerable improvement on (3.4). A generalization of this method to ground ring $\mathbf{Z}/q\mathbf{Z}$ is reported in **Ree85**.

As an illustration, suppose we are to find the minimal relation spanning

$$S = [0, 0, 0, 1, 16, 170, 1520, 12411, 96096, 719860, \ldots].$$

Following the scheme (12.1),

i	W_i	U_i	V_i	k_i
0		1	Y	0
1	0	1	Y^2	1
2	0	1	Y^3	2
3	0	1	Y^4	3
4	1	$1 - Y^4$	Y	-3
5	16	$1 - 16Y - Y^4$	Y^2	-2
6	-86	$1 - 16Y + 86Y^2 - Y^4$	Y^3	-1
7	176	$1 - 16Y + 86Y^2 - 176Y^3 - Y^4$	Y^4	0
8	-106	$1 - 16Y + 86Y^2 - 176Y^3 + 105Y^4$	$R(Y)$	0
9	0	$1 - 16Y + 86Y^2 - 176Y^3 + 105Y^4$	Y	$1 \cdot R(Y)$

where $R(Y)$ denotes $(-Y + 16Y^2 - 86Y^3 + 176Y^4 + Y^5)/106$. Further elements of this LFSR sequence would give $W_i = 0$, $U_i = U_8$, $V_i = Y^k R(Y)$, $k_i = i - 8$ for $i > 8$. Reversing U_8 gives the auxiliary polynomial $J = \mathbf{E}^4 - 16\mathbf{E}^3 + 86\mathbf{E}^2 - 176\mathbf{E} + 105 = 0$, that is S satisfies the relation

$$S_{n+4} - 16S_{n+3} + 86S_{n+2} - 176S_{n+1} + 105S_n = 0.$$

Algorithms reported by **Sen92** and **Ris74** compute the rank and inverse resp. of an individual numerical $n \times n$ Toeplitz matrix, at a cost of order n^2 time. The method involves decomposition into triangular matrices, and does not appear to compete with ours for number walls.

13. Hideous Numerical Example

In the number-wall diagrammed, all arithmetic (including division) is to be done modulo $p = 5$. The entire table wraps around cyclically with n. The LFSR order is $r = 21$ [hardly overwhelming news, since $r \leq n$ for any (periodic) sequence satisfying $\mathbf{E}^n - 1 \ = \ 0$].

Diagram Modulo 5 wall of test sequence S_n for $n = 1(1)21$ ($S_n = 3^{k(k+1)/2-n}$ with $k = [\sqrt{2n} + \frac{1}{2}]$.)

21	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Perturbing S_{10} by subtracting X causes the following changes around the frames of the 5x5 window with NE corner at $S_{1,9}$. [The notation is as in §4 Diagram. Only terms significant to the inductive step of the proof of Lemma (4.9) are retained, along with the dominant term of the remainder; missing terms are indicated by a final '+'. Components not in range of the relevant lemma are omitted from vectors.]

$$
\begin{aligned}
A &= [4,\ 3,\ 1,\ 2,\ 4,\ 3,\ 1+4X] \\
B &= [4,\ 3,\ 1,\ 2,\ 4,\ 3,\ 1+X] \\
C &= [\ ,\ 3+4X+4X^5+X^6,\ 1+4X^5,\ 2+4X+3X^2+X^3+X^4, \\
&\qquad 4+X+3X^2+4X^3,\ 3+3X+X^2,\ 1+4X] \\
D &= [\ ,\ 2+X+X^5+X^6,\ 1+X^5,\ 3+X+2X^2+4X^3+2X^4, \\
&\qquad 4+X+3X^2,\ 2+2X+3X^2,\ 1+X]
\end{aligned}
$$

$$
\begin{aligned}
E &= [1,\ 1,\ 1,\ 1,\ 1,\ 1,\ 1] \\
F &= [1,\ 4,\ 2,\ 0,\ 3,\ 4,\ 2] \\
G &= [2+X+,\ 3+,\ 1+2X+,\ 4+X+,\ 1+X+,\ 4+2X,\ 1] \\
H &= [4+4X+,\ 1+,\ 4+4X+,\ 3+4X+,\ 3X+,\ 2+3X+,\ 4+X]
\end{aligned}
$$

$$\begin{aligned} M &= N = [\ ,\ 4X^5,\ 3X^4,\ X^3,\ 2X^2,\ 4X,\ 3] \\ P &= Q = 2 \qquad U = V = 2/X \\ R &= 2 + 4X + 3X^2 + X^3 + 2X^4 + 2X^5 + 2X^6 + \\ T &= 3 + X + 2X^2 + 4X^3 + 3X^4 + 3X^5 + X^6 + \end{aligned}$$

To illustrate the perturbed frame results of §4, we show the dominant term of the error in (4.7),(4.8),(4.9):

$$\begin{aligned} \mathrm{err}(C) &= [\ ,\ ,\ 4X^5+,\ X^5+,\ 2X^3+,\ 2X^3+,\ 2X+] \\ \mathrm{err}(D) &= [\ ,\ ,\ 3X^5+,\ 2X^5+,\ 4X^3+,\ 2X^3+,\ X+] \\ \mathrm{err}(PT/QR) &= 4X^6+ \\ \mathrm{err}(E+F+G+H) &= [0+,\ 3X+,\ 4X+,\ 3X+,\ 3X+,\ X+,\ 4X+] \end{aligned}$$

Now suppose that we knew the Frame Theorems for 4×4 only, and had computed the original table as far as the bottom of the 5×5 window. To compute the South frames of this square, we might proceed thus: First perturb the table as above, then find N by (4.2), D by (4.3), H by (3.6) since N is now nonzero, and finally let $X \to 0$. The inductive versions of these theorems for $g-1$ in the form required in the perturbed table for $1 \le k \le k+1$ are:

$$\begin{aligned} N_k &= (-)^{(g-1)(k-1)} M_k B_{k-1}/Ak - 1 \\ D_k &= (N_k/U)(QE_{k-1}/A_{k-1} - (-1)^k(PF_{k-1}/B_{k-1} - VC_k/M_k)) \\ H_k &= ({D_k}^2 - D_{k-1}D_{k+1})/N_k \end{aligned}$$

Notice how we need to compute D to $\mathcal{O}(X^6)$ in order to be able to compute H_2 to $\mathcal{O}(X)$ — i.e. at all — because $N_2 = 4X^5$.

But all this is idle speculation, since we do know the Frame Theorems for all g, and can simply compute the original frames directly by (5.1).

Abstract

Let H be the Hankel matrix formed from a sequence of real numbers $S = \{a_0 = 1, a_1, a_2, a_3, ...\}$, and let L denote the lower triangular matrix obtained from the Gaussian column reduction of H. This paper gives a matrix-theoretic proof that the associated Stieltjes matrix S_L is a tri-diagonal matrix. It is also shown that for any sequence (of nonzero real numbers) $T = \{d_0 = 1, d_1, d_2\ , d_3, ...\}$ there are infinitely many sequences such that the determinant sequence of the Hankel matrix formed from those sequences is T.

1. Introduction. In this paper we give a matrix-theoretic proof (Theorem 2.1) of one of the main theorems in [1]. In Section 2 we discuss the connection between the decomposition of a Hankel matrix and Stieltjes matrices, and in Section 3 we discuss the connection between certain lattice paths and Hankel matrices. Section 4 presents an explicit formula for the decomposition of a Hankel matrix.

Definition 1.1. Let $S = \{a_0 = 1, a_1, a_2, a_3, ...\}$ be a sequence of real numbers. The Hankel matrix generated by S is the infinite matrix

$$H = \begin{bmatrix} 1 & a_1 & a_2 & a_3 & a_4 & . \\ a_1 & a_2 & a_3 & a_4 & a_5 & . \\ a_2 & a_3 & a_4 & a_5 & a_6 & . \\ a_3 & a_4 & a_5 & a_6 & a_7 & . \\ a_4 & a_5 & a_6 & a_7 & a_8 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

Definition 1.2. A lower triangular matrix

$$L = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ l_{10} & 1 & 0 & 0 & 0 & . \\ l_{20} & l_{21} & 1 & 0 & 0 & . \\ l_{30} & l_{31} & l_{32} & 1 & 0 & . \\ l_{40} & l_{41} & l_{42} & l_{43} & 1 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

is said to be a Riordan matrix if there exist Taylor series $g(x) = 1 + a_1x + a_2x^2 + ... + a_nx^n + ...$ and $f(x) = x + b_2x^2 + b_3x^3 + ... + b_nx^n + ...$ such that for every $k \geq 0$ the k-th column has ordinary generating function $g(x)(f(x))^k$.

Definition 1.3. The Stieltjes matrix of a lower triangular matrix L is the matrix S_L which satisfies $LS_L = L^r$ where L^r is the matrix obtained from L by deleting the first row of L.

Thus

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ l_{10} & 1 & 0 & 0 & 0 & . \\ l_{20} & l_{21} & 1 & 0 & 0 & . \\ l_{30} & l_{31} & l_{32} & 1 & 0 & . \\ l_{40} & l_{41} & l_{42} & l_{43} & 1 & . \\ . & . & . & . & . & . \end{bmatrix} S_L = \begin{bmatrix} l_{10} & 1 & 0 & 0 & 0 & . \\ l_{20} & l_{21} & 1 & 0 & 0 & . \\ l_{30} & l_{31} & l_{32} & 1 & 0 & . \\ l_{40} & l_{41} & l_{42} & l_{43} & 1 & . \\ . & . & . & . & . & . \end{bmatrix}$$

and so

$$S_L = L^{-1}L^r = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ -l_{10} & 1 & 0 & 0 & 0 & . \\ \times & -l_{21} & 1 & 0 & 0 & . \\ \times & \times & -l_{32} & 1 & 0 & . \\ \times & \times & \times & -l_{43} & 1 & . \\ . & . & . & . & . & . \end{bmatrix} \begin{bmatrix} l_{10} & 1 & 0 & 0 & 0 & . \\ l_{20} & l_{21} & 1 & 0 & 0 & . \\ l_{30} & l_{31} & l_{32} & 1 & 0 & . \\ l_{40} & l_{41} & l_{42} & l_{43} & 1 & . \\ . & . & . & . & . & . \end{bmatrix}$$

$$= \begin{bmatrix} b_0 & 1 & 0 & 0 & 0 & . \\ c_0 & b_1 & 1 & 0 & 0 & . \\ \times & c_1 & b_2 & 1 & 0 & . \\ \times & \times & c_2 & b_3 & 1 & . \\ \times & \times & \times & c_3 & b_4 & . \\ . & . & . & . & . & . \end{bmatrix}$$

where

$$b_0 = l_{10},\ b_k = l_{k+1,k} - l_{k,k-1},\ k > 0,$$

$$c_0 = l_{2,0} - l_{1,0}^2,\ c_k = (l_{k,k-1}l_{k+1,k} - l_{k+1,k-1}) - l_{k+1,k}^2 + l_{k+2,k},\ k > 0.$$

Definition 1.4. Let L and S_L be as in Definition 1.3. We define

$$D_L = \begin{bmatrix} d_0 & 0 & 0 & 0 & 0 & . \\ 0 & d_1 & 0 & 0 & 0 & . \\ 0 & 0 & d_2 & 0 & 0 & . \\ 0 & 0 & 0 & d_3 & 0 & . \\ 0 & 0 & 0 & 0 & d_4 & . \\ . & . & . & . & . & . \end{bmatrix}$$

to be the diagonal matrix with diagonal entries given by $d_0 = 1$, $d_{k+1} = d_k c_k$ for $k > 0$.

2. Stieltjes and Hankel Matrices.

The following two theorems are proved in [1].

Theorem 2.1. Let L be a lower triangular matrix and let $D = D_L$ be the diagonal matrix with nonzero diagonal entries $\{d_i\}$ as in Definition 1.4. Then LDL^t is a Hankel matrix if and only if S_L is a tri-diagonal matrix, i.e. if and only if

$$S_L = \begin{bmatrix} b_0 & 1 & 0 & 0 & 0 & . \\ c_0 & b_1 & 1 & 0 & 0 & . \\ 0 & c_1 & b_2 & 1 & 0 & . \\ 0 & 0 & c_2 & b_3 & 1 & . \\ 0 & 0 & 0 & c_3 & b_4 & . \\ . & . & . & . & . & . \end{bmatrix}$$

where $b_0 = l_{1,0}$, $c_0 = d_1$, $b_k = l_{k+1,k} - l_{k,k-1}$, $c_k = \frac{d_{k+1}}{d_k}$, $k \geq 1$.

PROOF. Let $H = LDL^t$ be a Hankel matrix. Then

$L = H(DL^t)^{-1}$,

$L^r = (H(DL^t)^{-1})^r = H^r(DL^t)^{-1}$,

$S_L = L^{-1}L^r = L^{-1}(H^r(DL^t)^{-1}) = (L^{-1}H^r)(DL^t)^{-1}$.

Since H is a Hankel matrix, deleting the first row has the same effect as deleting the first column.

$$L^{-1}H = DL^t = \begin{bmatrix} d_0 & d_0 l_{10} & d_0 l_{20} & d_0 l_{3,0} & d_0 l_{4,0} & . \\ 0 & d_1 & d_1 l_{21} & d_1 l_{31} & d_1 l_{41} & . \\ 0 & 0 & d_2 & d_2 l_{32} & d_2 l_{42} & . \\ 0 & 0 & 0 & d_3 & d_3 l_{43} & . \\ 0 & 0 & 0 & 0 & d_4 & . \\ . & . & . & . & . & . \end{bmatrix},$$

$$L^{-1}H^r = L^{-1}H^c = (L^{-1}H)^c = \begin{bmatrix} d_0 l_{10} & d_0 l_{20} & d_0 l_{30} & d_0 l_{4,0} & . \\ d_1 & d_1 l_{21} & d_1 l_{31} & d_1 l_{41} & . \\ 0 & d_2 & d_2 l_{32} & d_2 l_{42} & . \\ 0 & 0 & d_3 & d_3 l_{43} & . \\ 0 & 0 & 0 & d_4 & . \\ . & . & . & . & . \end{bmatrix},$$

$$S_L = (L^{-1}H)^c(DL^t)^{-1} = \begin{bmatrix} d_0l_{10} & d_0l_{20} & d_0l_{30} & d_0l_{4,0} & . \\ d_1 & d_1l_{21} & d_1l_{31} & d_1l_{41} & . \\ 0 & d_2 & d_2l_{32} & d_2l_{42} & . \\ 0 & 0 & d_3 & d_3l_{43} & . \\ 0 & 0 & 0 & d_4 & . \\ . & . & . & . & . \end{bmatrix} \begin{bmatrix} \frac{1}{d_0} & \times & \times & \times & \times & . \\ 0 & \frac{1}{d_1} & \times & \times & \times & . \\ 0 & 0 & \frac{1}{d_2} & \times & \times & . \\ 0 & 0 & 0 & \frac{1}{d_3} & \times & . \\ 0 & 0 & 0 & 0 & \frac{1}{d_4} & . \\ . & . & . & . & . & . \end{bmatrix}$$

$$= \begin{bmatrix} b_0 & 1 & 0 & 0 & 0 & . \\ c_0 & b_1 & 1 & 0 & 0 & . \\ 0 & c_1 & b_2 & 1 & 0 & . \\ 0 & 0 & c_2 & b_3 & 1 & . \\ 0 & 0 & 0 & c_3 & b_4 & . \\ . & . & . & . & . & . \end{bmatrix}$$

where

$$b_0 = l_{1,0}\ , \quad c_0 = \frac{d_1}{d_0} = d_1\ , \quad b_k = l_{k+1,k} - l_{k,k-1}\ , \quad c_k = \frac{d_{k+1}}{d_k}\ , \quad k \geq 1.$$

Conversely, let S_L be a tri-diagonal matrix and let $H = LDL^t$. Then
$L^{-1}H^r = L^{-1}(LDL^t)^r = L^{-1}(L^rDL^t) = (L^{-1}L^r)DL^t = S_LDL^t$

$$= \begin{bmatrix} b_0 & 1 & 0 & 0 & 0 & . \\ c_0 & b_1 & 1 & 0 & 0 & . \\ 0 & c_1 & b_2 & 1 & 0 & . \\ 0 & 0 & c_2 & b_3 & 1 & . \\ 0 & 0 & 0 & c_3 & b_4 & . \\ . & . & . & . & . & . \end{bmatrix} \begin{bmatrix} d_0 & d_0l_{10} & d_0l_{20} & d_0l_{3,0} & d_0l_{4,0} & . \\ 0 & d_1 & d_1l_{21} & d_1l_{31} & d_1l_{41} & . \\ 0 & 0 & d_2 & d_2l_{32} & d_2l_{42} & . \\ 0 & 0 & 0 & d_3 & d_3l_{43} & . \\ 0 & 0 & 0 & 0 & d_4 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

Therefore
$(L^{-1}H^r)_{n,k} = c_{n-1}d_{n-1}l_{k,n-1} + b_nd_nl_{k,n} + d_{n+1}l_{k,n+1}$
$= \frac{d_n}{d_{n-1}}d_{n-1}l_{k,n-1} + b_nd_nl_{k,n} + c_nd_nl_{k,n+1}$
$= d_n(l_{k,n-1} + b_nl_{k,n} + c_nl_{k,n+1})$
$= d_nl_{k+1,n} = (DL^t)_{n,k+1} = (DL^t)^c_{n,k} = (L^{-1}H)^c_{n,k} = (L^{-1}H^c)_{n,k}$.
We have shown that $L^{-1}H^r = L^{-1}H^c$, and so $H^r = H^c$. Hence H is a Hankel matrix. ■

Theorem 2.2. L is a Riordan matrix (i.e. $b_k = b_1 = b$ and $c_k = c_1 = c$ for $k \geq 1$) if and only if $f = x(1 + bf + cf^2)$ and

$$g = \frac{1}{1 - xb_0 - xc_0f}\ ,$$

where f, g are as in Definition 1.2.

See [1] for the proof.

Corollary 2.3. Let $T = \{d_0 = 1, d_1, d_2\ , d_3, ...\}$ be any sequence of (nonzero) real numbers. Then there exists a sequence $S = \{a_0 = 1, a_1, a_2, a_3, ...\}$ such that T is equal to the sequence of diagonal entries of D in the decomposition $H = LDL^t$ of the Hankel matrix generated by S .

PROOF. As in Theorem 2.1, let $c_0 = d_1$, $c_k = \frac{d_{k+1}}{d_k}$, $k \geq 1$, and form the Stieltjes matrix

$$S_L = \begin{bmatrix} b_0 & 1 & 0 & 0 & 0 & . \\ c_0 & b_1 & 1 & 0 & 0 & . \\ 0 & c_1 & b_2 & 1 & 0 & . \\ 0 & 0 & c_2 & b_3 & 1 & . \\ 0 & 0 & 0 & c_3 & b_4 & . \\ . & . & . & . & . & . \end{bmatrix}$$

where the b_is are arbitrary. By Definition 1.3 there is a lower triangular matrix L such that $LS_L = L^r$. Let S be the sequence formed by the first column of L and let H denote the Hankel matrix generated by S. By Theorem 2.1 the diagonal entries of D in the decomposition $H = LDL^t$ form the sequence T. ■

Example 2.4. Let $T = \{1, 1, 2, 5, 14, 42, 132, ...\}$ be the Catalan sequence (A000108 in [2]) and let

$$S_L = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & . \\ 1 & 0 & 1 & 0 & 0 & . \\ 0 & 2 & 0 & 1 & 0 & . \\ 0 & 0 & \frac{5}{2} & 0 & 1 & . \\ 0 & 0 & 0 & \frac{14}{5} & 0 & . \\ . & . & . & . & . & . \end{bmatrix}.$$

Then

$$L = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ 0 & 1 & 0 & 0 & 0 & . \\ 1 & 0 & 1 & 0 & 0 & . \\ 0 & 3 & 0 & 1 & 0 & . \\ 3 & 0 & \frac{11}{2} & 0 & 1 & . \\ . & . & . & . & . & . \end{bmatrix},$$

$$LDL^t = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ 0 & 1 & 0 & 0 & 0 & . \\ 1 & 0 & 1 & 0 & 0 & . \\ 0 & 3 & 0 & 1 & 0 & . \\ 3 & 0 & \frac{11}{2} & 0 & 1 & . \\ . & . & . & . & . & . \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ 0 & 1 & 0 & 0 & 0 & . \\ 0 & 0 & 2 & 0 & 0 & . \\ 0 & 0 & 0 & 5 & 0 & . \\ 0 & 0 & 0 & 0 & 14 & . \\ . & . & . & . & . & . \end{bmatrix} \begin{bmatrix} 1 & 0 & 1 & 0 & 3 & . \\ 0 & 1 & 0 & 3 & 0 & . \\ 0 & 0 & 1 & 0 & \frac{11}{2} & . \\ 0 & 0 & 0 & 1 & 0 & . \\ 0 & 0 & 0 & 0 & 1 & . \\ . & . & . & . & . & . \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 0 & 1 & 0 & 3 & . \\ 0 & 1 & 0 & 3 & 0 & . \\ 1 & 0 & 3 & 0 & 14 & . \\ 0 & 3 & 0 & 14 & 0 & . \\ 3 & 0 & 14 & 0 & \frac{167}{2} & . \\ . & . & . & . & . & . \end{bmatrix} = H.$$

3. Lattice Paths and Hankel Matrices

We consider those lattice paths in the Cartesian plane running from $(0,0)$ that use steps from $S = \{u = (1,1),\ h = (1,0),\ d = (1,-1)\}$ with assigned weights 1 for u, w_1 for h and w_2 for d. Let $L(n,k)$ be the set of paths that never go below the x-axis and end at (n,k). The weight of a path is the product of the weights of its steps. Let $l_{n,k}$ be the sum of the weights of all the paths in $L(n,k)$. See also [3], [4].

Theorem 3.1. Let $L = (l_{n,k})_{n,k\geq 0}$. Then L is a lower triangular matrix, the Stieltjes matrix of L is

$$S_L = \begin{bmatrix} w_1 & 1 & 0 & 0 & 0 & . \\ w_2 & w_1 & 1 & 0 & 0 & . \\ 0 & w_2 & w_1 & 1 & 0 & . \\ 0 & 0 & w_2 & w_1 & 1 & . \\ 0 & 0 & 0 & w_2 & w_1 & . \\ . & . & . & . & . & . \end{bmatrix}$$

and $H = LDL^t$ is the Hankel matrix generated by the first column of L and $d_k = w_2^k$ for $k > 0$.

PROOF. From Theorem 2.1. ∎

Example 3.2. For $w_1 = 0,\ w_2 = 1$, L is the Catalan matrix. For $w_1 = t,\ w_2 = 1$, L is the t-Motzkin matrix. In both cases D is the identity matrix. For example, when $t = 1$,

$$L = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & . \\ 1 & 1 & 0 & 0 & 0 & . \\ 2 & 2 & 1 & 0 & 0 & . \\ 4 & 5 & 3 & 1 & 0 & . \\ 9 & 12 & 9 & 4 & 1 & . \\ . & . & . & . & . & . \end{bmatrix},$$

$$LDL^t = \begin{bmatrix} 1 & 1 & 2 & 4 & 9 & . \\ 1 & 2 & 4 & 9 & 21 & . \\ 2 & 4 & 9 & 21 & 51 & . \\ 4 & 9 & 21 & 51 & 127 & . \\ 9 & 21 & 51 & 127 & 323 & . \\ . & . & . & . & . & . \end{bmatrix} = H$$

where $S = \{1, 1, 2, 4, 9, 21, 51, ...\}$ is the Motzkin sequence A001006.

Theorem 3.3. If w_1, w_2 depend on the height k, i.e. $w_1(k) = b_k$ and $w_2(k+1) = c_k$, then

$$S_L = \begin{bmatrix} b_0 & 1 & 0 & 0 & 0 & . \\ c_0 & b_1 & 1 & 0 & 0 & . \\ 0 & c_1 & b_2 & 1 & 0 & . \\ 0 & 0 & c_2 & b_3 & 1 & . \\ 0 & 0 & 0 & c_3 & b_4 & . \\ . & . & . & . & . & . \end{bmatrix}$$

and $H = LDL^t$ is the Hankel matrix generated by the first column of L and $d_k = \Pi_{i\leq k} c_i$.

PROOF. From Theorem 2.1. ∎

See Example 2.4 for an illustration.

4. Gaussian Column Reduction

Let $S = \{a_0 = 1, a_1, a_2, a_3, ...\}$ be a sequence of real numbers and let H denote the Hankel matrix generated by S. All the results in this section are well-known in matrix theory. We shall express the entries of L in term of S. We assume that H is positive definite.

Lemma 4.1. The decomposition of a positive definite Hankel matrix $H = LDU$ is unique and $U = L^t$, where L is a lower triangular matrix with diagonal entries 1, D is a diagonal matrix and U is an upper triangular matrix with diagonal entries 1.

PROOF. Let $LDU = H = L_1D_1U_1$. Then $DUU_1^{-1} = L^{-1}L_1D_1$ is both an upper and lower triangular matrix, hence $UU_1^{-1} = L^{-1}L_1 = I$ is the infinite identity matrix. ■

Let H_n be the truncated submatrix of H with $n \geq 0$. For example,

$$H_3 = \begin{bmatrix} 1 & a_1 & a_2 & a_3 \\ a_1 & a_2 & a_3 & a_4 \\ a_2 & a_3 & a_4 & a_5 \\ a_3 & a_4 & a_5 & a_6 \end{bmatrix}, \quad H_4 = \begin{bmatrix} 1 & a_1 & a_2 & a_3 & a_4 \\ a_1 & a_2 & a_3 & a_4 & a_5 \\ a_2 & a_3 & a_4 & a_5 & a_6 \\ a_3 & a_4 & a_5 & a_6 & a_7 \\ a_4 & a_5 & a_6 & a_7 & a_8 \end{bmatrix}.$$

Let $H_n(k)$ be the matrix obtained from H_n by replacing the last column of H_n by $a_k, a_{k+1}, a_{k+2}, ..., a_{k+n}$. For example,

$$H_3(1) = \begin{bmatrix} 1 & a_1 & a_2 & a_1 \\ a_1 & a_2 & a_3 & a_2 \\ a_2 & a_3 & a_4 & a_3 \\ a_3 & a_4 & a_5 & a_4 \end{bmatrix}, \quad H_3(5) = \begin{bmatrix} 1 & a_1 & a_2 & a_5 \\ a_1 & a_2 & a_3 & a_6 \\ a_2 & a_3 & a_4 & a_7 \\ a_3 & a_4 & a_5 & a_8 \end{bmatrix}.$$

.

Let $h_i = \det H_i$ and define an infinite upper triangular matrix $R = (r_{n,k})$ in term of (n,k)-cofactor of H_k by $r_{n,k} = 0$ for $k < n$, and

$$r_{n,k} = \frac{1}{h_{k-1}}(-1)^{n+k+2} \det \begin{bmatrix} 1 & a_1 & a_2 & . & a_{k-1} \\ a_1 & a_2 & a_3 & .. & a_k \\ a_2 & a_3 & a_4 & . & a_{k+1} \\ . & . & . & . & .. \\ a_{n-1} & a_n & a_{n+1} & . & a_{k+n-2} \\ a_{n+1} & a_{n+2} & a_{n+3} & . & a_{k+n} \\ . & . & . & . & . \\ a_k & a_{k+1} & a_{k+2} & . & a_{k+k} \end{bmatrix}$$

for $k \geq n$. For example,

$$r_{2,4} = \frac{1}{h_3}(-1)^{(2+4)+2} \det \begin{bmatrix} 1 & a_1 & a_2 & a_3 \\ a_1 & a_2 & a_3 & a_4 \\ a_3 & a_4 & a_5 & a_6 \\ a_4 & a_5 & a_6 & a_7 \end{bmatrix}.$$

Remark 4.2. $HR = LD$, where $L = (l_{n,k})$ is the Gaussian column reduction of the Hankel matrix H and D is the diagonal matrix with diagonal entries $\{d_i\}$, $R^{-1} = L^t$ with $d_i = \frac{h_i}{h_{i-1}}$ and $l_{n,k} = \frac{1}{h_{k-1}} \det H_k(n)$.

Remark 4.3. If L is a Riordan matrix, then for $i \geq 1$, $c = c_i = \frac{d_{i+1}}{d_i} = \frac{h_{i+1}h_{i-1}}{h_i h_i}$ and $b = b_i = l_{i+1,i} - l_{i,i-1} = \frac{1}{h_{i-1}} \det H_i(i+1) - \frac{1}{h_{i-2}} \det H_{i-1}(i)$ is a recurrence relation for the sequence S.

Example 4.4. Let $S = \{1, 3, 13, 63, 321, 1683, 8989, 48639, 265729, ...\}$ be the central Delannoy numbers A001850, and let H be the Hankel matrix generated by S. Then

$$H = \begin{bmatrix} 1 & 3 & 13 & 63 & . \\ 3 & 13 & 63 & 321 & . \\ 13 & 63 & 321 & 1683 & . \\ 63 & 321 & 1683 & 8989 & . \\ . & . & . & . & . \end{bmatrix},$$

$$R = \begin{bmatrix} 1 & -3 & 5 & -9 & . \\ 0 & 1 & -6 & 21 & . \\ 0 & 0 & 1 & -9 & . \\ 0 & 0 & 0 & 1 & . \\ . & . & . & . & . \end{bmatrix},$$

$$LD = HR = \begin{bmatrix} 1 & 0 & 0 & 0 & . \\ 3 & 4 & 0 & 0 & . \\ 13 & 24 & 8 & 0 & . \\ 63 & 132 & 72 & 16 & . \\ . & . & . & . & . \end{bmatrix},$$

$$R^t HR = D = \begin{bmatrix} 1 & 0 & 0 & 0 & . \\ 0 & 4 & 0 & 0 & . \\ 0 & 0 & 8 & 0 & . \\ 0 & 0 & 0 & 16 & . \\ . & . & . & . & . \end{bmatrix},$$

$$L = HRD^{-1} = \begin{bmatrix} 1 & 0 & 0 & 0 & . \\ 3 & 1 & 0 & 0 & . \\ 13 & 6 & 1 & 0 & . \\ 63 & 33 & 9 & 1 & . \\ . & . & . & . & . \end{bmatrix},$$

$$S_L = L^{-1}L^r = R^t L^r = \begin{bmatrix} 1 & 0 & 0 & 0 & . \\ -3 & 1 & 0 & 0 & . \\ 5 & -6 & 1 & 0 & . \\ -9 & 21 & -9 & 1 & . \\ . & . & . & . & . \end{bmatrix} \begin{bmatrix} 3 & 1 & 0 & 0 & 0 & . \\ 13 & 6 & 1 & 0 & 0 & . \\ 63 & 33 & 9 & 1 & 0 & . \\ 321 & 180 & 62 & 12 & 1 & . \\ . & . & . & . & . & . \end{bmatrix}$$

$$= \begin{bmatrix} 3 & 1 & 0 & 0 & . \\ 4 & 3 & 1 & 0 & . \\ 0 & 2 & 3 & 1 & . \\ 0 & 0 & 2 & 3 & . \\ . & . & . & . & . \end{bmatrix},$$

$$LDL^t = \begin{bmatrix} 1 & 0 & 0 & 0 & . \\ 3 & 1 & 0 & 0 & . \\ 13 & 6 & 1 & 0 & . \\ 63 & 33 & 9 & 1 & . \\ . & . & . & . & . \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 & . \\ 0 & 4 & 0 & 0 & . \\ 0 & 0 & 8 & 0 & . \\ 0 & 0 & 0 & 16 & . \\ . & . & . & . & . \end{bmatrix} \begin{bmatrix} 1 & 3 & 13 & 63 & . \\ 0 & 1 & 6 & 33 & . \\ 0 & 0 & 1 & 9 & . \\ 0 & 0 & 0 & 1 & . \\ . & . & . & . & . \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 3 & 13 & 63 & . \\ 3 & 13 & 63 & 321 & . \\ 13 & 63 & 321 & 1683 & . \\ 63 & 321 & 1683 & 8989 & . \\ . & . & . & . & . \end{bmatrix} = H.$$

Remark 4.5. If H is the Hankel matrix corresponding to a sequence S, then by Theorem 3.1 and Theorem 3.3 we may use lattice paths to find L, the Gaussian column reduction of H.

Acknowledgment. The author would like to thank Professor Ralph Turner for his help in rewriting the paper.

Email addresses: pp@scs.howard.edu, wwoan@howard.edu

Abstract: A Dyck path of length 2n is a path in two-space from (0,0) to (2n,0) which uses only steps (1,1) (north-east) and (1,-1) (south-east). Further, a Dyck path does not go below the x-axis. A peak on a Dyck path is a node that is immediately preceded by a north-east step and immediately followed by a south-east step. A peak is at height k if its y-coordinate is k. Let G_k(x) be the generating function for the number of Dyck paths of length 2n with no peaks at height k with k >= 1. It is known that G_1(x) is the generating function for the Fine numbers (sequence A000957). In this paper, we derive the recurrence

$$G_k(x) = 1 / (1-xG_{k-1}(x)), k >= 2, G_1(x) = 2 / (1+2x+sqrt{1-4x}).$$

It is interesting to see that in the case k=2 we get G_2(x)=1+xC(x), where C(x) is the generating function for the ubiquitous Catalan numbers (A000108). This means that the number of Dyck paths of length 2n+2, n >= 0, with no peaks at height 2 is the Catalan number c_n = 1 / (n+1) Binomial(2n, n). We also provide a combinatorial proof for this last fact by introducing a bijection between the set of all Dyck paths of length 2n+2 with no peaks at height 2 and the set of all Dyck paths of length 2n.

Keywords: Dyck paths, Catalan number, Fine number, generating function.

Abstract

A Dyck path of length $2n$ is a path in two-space from $(0,0)$ to $(2n,0)$ which uses only steps $(1,1)$ (north-east) and $(1,-1)$ (south-east). Further, a Dyck path does not go below the x-axis. A peak on a Dyck path is a node that is immediately preceded by a north-east step and immediately followed by a south-east step. A peak is at height k if its y-coordinate is k. Let $G_k(x)$ be the generating function for the number of Dyck paths of length $2n$ with no peaks at height k with $k \geq 1$. It is known that $G_1(x)$ is the generating function for the Fine numbers (sequence A000957 in [6]). In this paper, we derive the recurrence

$$G_k(x) = \frac{1}{1 - xG_{k-1}(x)},\ k \geq 2,\ G_1(x) = \frac{2}{1 + 2x + \sqrt{1-4x}}.$$

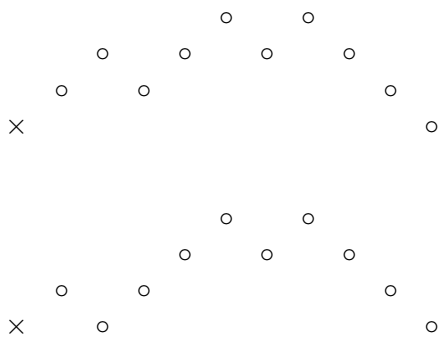
It is interesting to see that in the case $k = 2$ we get $G_2(x) = 1 + xC(x)$, where $C(x)$ is the generating function for the ubiquitous Catalan numbers (A000108). This means that the number of Dyck paths of length $2n+2$, $n \geq 0$, with no peaks at height 2 is the Catalan number $c_n = \frac{1}{n+1}\binom{2n}{n}$. We also provide a combinatorial proof for this last fact by introducing a bijection between the set of all Dyck paths of length $2n+2$ with no peaks at height 2 and the set of all Dyck paths of length $2n$.

Keywords: Dyck paths, Catalan number, Fine number, generating function.

1 Introduction

In [1] it was shown that Fine numbers (A000957) count Dyck paths with no peaks at height 1. One of the results of this paper is that the Catalan numbers (A000108) count Dyck paths with no peaks at height 2. This provides yet another combinatorial setting for the Catalan numbers (cf. [4], [5], [6], [7]).

A Dyck path is a path in two-space which starts at the origin, stays above the x-axis, and allows only steps of $(1,1)$ (i.e. north-east) and $(1,-1)$ (i.e. south-east). A Dyck path ends on the x-axis. A Dyck path therefore has even length with the number of north-east steps equal to the number of south-east steps. A lattice point on the path is called a peak if it is immediately preceded by a north-east step and immediately followed by a south-east step. A peak is at height k if its y-coordinate is k. Here are two Dyck paths each of length 10:



The first path has one peak at height 2 and two peaks at height 3. It has no peaks at height 1. The second path has one peak at height 1 and two at height 3. It has no peaks at height 2. Reference [1] contains much information about Dyck paths. It is known that the number of Dyck paths of length $2n$ is c_n, the n^{th} Catalan number, given by

$$c_n = \frac{1}{n+1}\binom{2n}{n}.$$

We will prove that the number of these paths with no peaks at height 2 is c_{n-1} . It is known [1] that the number of these paths with no peaks at height 1 is f_n, the n^{th} Fine number with generating function

$$F(x) = \frac{1}{1-x^2C^2(x)} = 1 + x^2 + 2x^3 + 6x^4 + 18x^5 + 57x^6 + 186x^7 + O\left(x^8\right)$$

where $C(x) = \frac{1-\sqrt{1-4x}}{2x}$ is the generating function for the Catalan numbers. See [1], [2], and [3] for further information about the Fine numbers. Theorem 2 below contains a proof that the Fine numbers count Dyck paths with no peaks at height 1. In Theorem 1, we obtain the recurrence

$$G_k(x) = \frac{1}{1-xG_{k-1}(x)}\ ,\ k \geq 2,$$

where $G_k(x)$ is the generating function for the number of Dyck paths of length $2n$ with no peaks at height k. In Section 3 we introduce a bijection between the set of all Dyck paths of length $2n$ and the set of all Dyck paths of length $2n+2$ with no peaks at height 2. This bijection provides a combinatorial proof that $G_2(x) = 1 + xC(x)$.

2 Theorems

We will use the fact that

$$F(x) = \sum_{n\geq 0} f_n x^n = \frac{C(x)}{1+xC(x)}.$$

Theorem 1: Let $G_m(x) = \sum_{n\geq 0} g(m,n)x^n$ be the generating function for Dyck paths of length $2n$ with no peaks at height m, $m \geq 1$. Then

$$G_m(x) = \frac{1}{1 - xG_{m-1}(x)} \quad ; \quad m \geq 2 \, .$$

PROOF. The set of all Dyck paths of length $2n$, $n \geq 0$, with no peaks at height m consists of the trivial path (the origin) and paths with general form shown in the diagram.

$$\begin{array}{ccc} & A & \\ \times & & B \end{array}$$

It starts with a north-east step followed by a segment labeled A which represents any Dyck path of length $2k$, $0 \leq k \leq n-1$, with no peaks at height $m-1$. A is followed by a south-east step followed by a segment labeled B which represents any Dyck path of length $2n-2-2k$ with no peaks at height m. Therefore

$$g(m,0) = 1, \; g(m,n) = \sum_{k=0}^{n-1} g(m-1,k)g(m,n-1-k) = \left[x^{n-1}\right] \{G_{m-1}(x)G_m(x)\}.$$

$$i.e. \quad g(m,0) = 1, \quad g(m,n) = [x^n] \{xG_{m-1}(x)G_m(x)\} \; ; \quad n \geq 1,$$

where $[x^k]$ denotes "coefficient of x^k in ". That is,

$$G_m(x) = 1 + x \, G_{m-1}(x)G_m(x) \, ,$$

or equivalently,

$$G_m(x) = \frac{1}{1 - xG_{m-1}(x)}$$

■

Theorem 2: The number of Dyck paths of length $2n$ with no peaks at height 1 is the Fine number f_n for $n \geq 0$.

PROOF. With the notation of Theorem 1, we will prove that

$$G_1 = \sum_{n=0}^{\infty} g(1,n)x^n = \frac{1}{1 - x^2C^2}$$

Obviously, $g(1,0) = 1$ and $g(1,1) = 0$. For $n \geq 2$, a Dyck path of length $2n$ with no peaks at height 1 has the form of the diagram in the proof of Theorem 1 with A any Dyck path of length $2k$, $1 \leq k \leq n-1$, and B a Dyck path of length $2n-2k-2$ with no peaks at height 1. Therefore, for $n \geq 2$, we have

$$\begin{aligned} g(1,n) &= \sum_{k=1}^{n-1} c_k \, g(1,n-k-1) = [x^{n-1}]\{C(x)G_1(x)\} - g(1,n-1) \\ &= [x^n]\{xC(x)G_1(x)\} - g(1,n-1) \end{aligned}$$

Therefore

$$\begin{aligned} G_1(x) &= 1 + \sum_{n\geq 2} g(1,n)x^n = 1 + xC(x)G_1(x) - x - xG_1(x) + x \\ &= 1 + xG_1(x) \, (C(x) - 1) = 1 + xG_1(x)xC^2(x) \end{aligned}$$

That is,

$$G_1(x) = \frac{1}{1 - x^2 C^2(x)}$$

■

Theorem 3: The number of Dyck paths of length $2n$ with no peaks at height 2 is the Catalan number c_{n-1} , for $n \geq 1$.

PROOF. From Theorem 1,

$$G_2(x) = \frac{1}{1 - xG_1(x)} = \frac{1}{1 - x\frac{C(x)}{1+xC(x)}} = 1 + xC(x)$$

■

Remark: In [1] it was shown that

$$\frac{f_{n-1}}{c_n} \to \frac{1}{9} \quad as \quad n \to \infty$$

Therefore

$$\frac{f_n}{c_n} \to \frac{4}{9} \quad as \quad n \to \infty$$

Since

$$\frac{c_{n-1}}{c_n} \to \frac{1}{4} \quad as \quad n \to \infty$$

we see that, for sufficiently large n, approximately $\frac{4}{9}$ of the Dyck paths of length $2n$ have no peaks at height 1, while approximately $\frac{1}{4}$ have no peaks at height 2.

Remark: $G_3(x) = \frac{2}{2-3x+x\sqrt{(1-4x)}} = 1 + x + 2x^2 + 4x^3 + 9x^4 + 22x^5 + 58x^6$
$+163x^7 + 483x^8 + 1494x^9 + O\left(x^{10}\right)$ (sequence A059019 in [6]).

3 A bijection between two Catalan families

We end with a bijection between the two Catalan families mentioned in this paper. Let Φ be the set of all Dyck paths of length $2n$ and let Ψ be the set of all Dyck paths of length $2n+2$ with no peaks at height 2. We define a bijection between Φ and Ψ as follows. First, starting with a Dyck path P from Φ, we obtain a Dyck path $\widehat{P}$ from Ψ using the following steps.

(1) Attach a Dyck path of length 2 to the left of P to produce P^*.

(2) Let S^* be a maximal sub-Dyck path of P^* with S^* having no peaks at height 1. To each such S^* add a north-east step at the beginning and a south-east step at the end to produce sub-Dyck path $\widetilde{S}$. This step produces a Dyck path $\widetilde{P}$.

(3) From $\widetilde{P}$ eliminate each Dyck path of length 2 that is to the immediate left of each $\widetilde{S}$. We now have a unique element $\widehat{P}$ of Ψ.

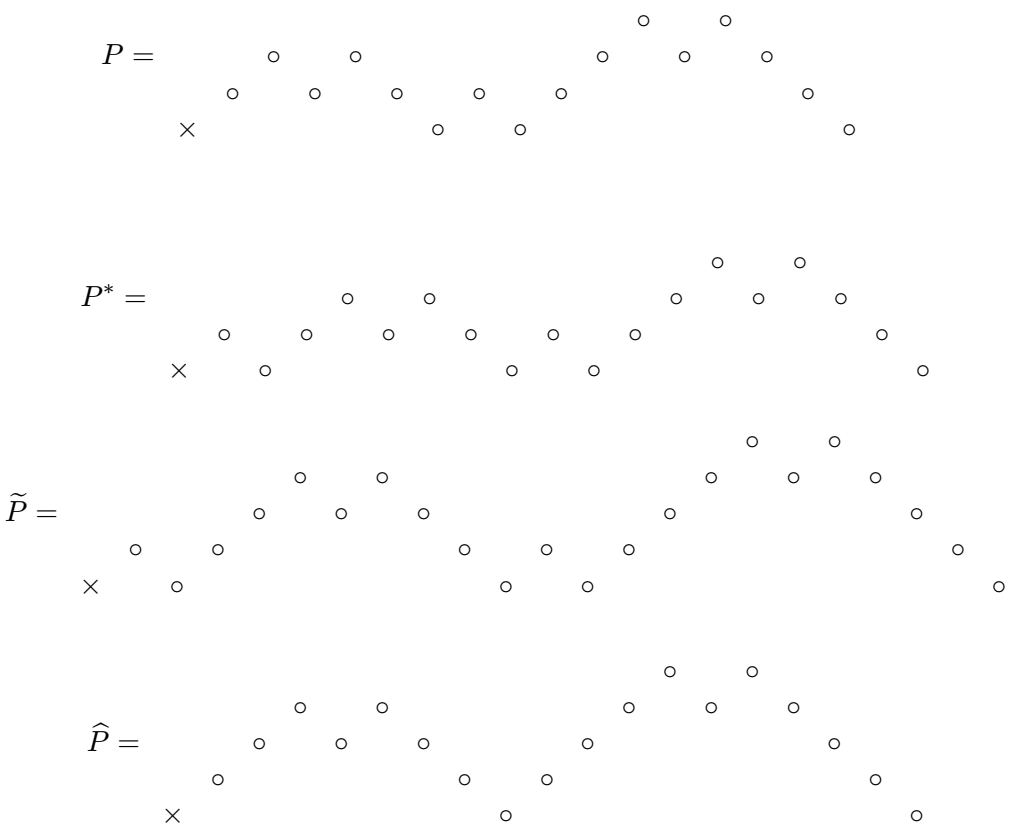
To obtain P from $\widehat{P}$, we reverse the steps as follows:

(1) Let $\widehat{S}$ be a sub-Dyck path of $\widehat{P}$ between two consecutive points on the x-axis with $\widehat{S}$ having no peaks at height 1. To each $\widehat{S}$ add a Dyck path of length 2 immediately to the left. This step produces a Dyck path $\widetilde{P}$.

(2) Let $\widetilde{S}$ be a maximal sub-Dyck path of $\widetilde{P}$. From each such $\widetilde{S}$ remove the left-most north-east step and the right-most south-east step to produce a sub-Dyck path S^*. This step produces a Dyck path P^* of length 2n+2.

(3) From P^* , remove the left-most Dyck path of length 2 to produce P.

For example, we obtain a Dyck path of length 18 with no peaks at height 2 starting with a Dyck path of length 16 as follows:



It is now easy to show that the Catalan numbers count paralellogram polynominoes (or Fat Path Pairs) with no columns at height 2 (see [7], p. 257).

Abstract

Exponentiating the hypergeometric series ${}_0F_L(1,1,\ldots,1;z)$, $L=0,1,2,\ldots$, *furnishes a recursion relation for the members of certain integer sequences* $b_L(n)$, $n=0,1,2,\ldots$. *For* $L>0$, *the* $b_L(n)$*'s are generalizations of the conventional Bell numbers,* $b_0(n)$. *The corresponding associated Stirling numbers of the second kind are also investigated. For* $L=1$ *one can give a combinatorial interpretation of the numbers* $b_1(n)$ *and of some Stirling numbers associated with them. We also consider the* $L\geq 1$ *analogues of Bell numbers for restricted partitions.*

The conventional Bell numbers [1] $b_0(n)$, $n=0,1,2,\ldots$, have a well-known exponential generating function

$$B_0(z)\equiv e^{(e^z-1)}=\sum_{n=0}^{\infty}b_0(n)\frac{z^n}{n!}, \tag{1}$$

which can be derived by interpreting $b_0(n)$ as the number of partitions of a set of n distinct elements. In this note we obtain recursion relations for related sequences of positive integers, called $b_L(n)$, $L=0,1,2,\ldots$,

[1] Permanent address: Quantum Processes Group, Open University, Milton Keynes, MK7 6AA, United Kingdom.

obtained by exponentiating the hypergeometric series ${}_0F_L(1,1,\ldots,1;z)$ defined by [2]:

$$ {}_0F_L(\underbrace{1,1,\ldots,1}_{L};z)=\sum_{n=0}^{\infty}\frac{z^n}{(n!)^{L+1}}, \tag{2}$$

(which we shall denote by ${}_0F_L(z)$) and which includes the special cases ${}_0F_0(z)\equiv e^z$ and ${}_0F_1(z)\equiv I_0(2\sqrt{z})$, where $I_0(x)$ is the modified Bessel function of the first kind. For $L>1$, the functions ${}_0F_L(z)$ are related to the so-called hyper-Bessel functions [3], [4], [5], which have recently found application in quantum mechanics [6], [7]. Thus we are interested in $b_L(n)$ given by

$$ e^{[\,{}_0F_L(z)-1]}=\sum_{n=0}^{\infty}b_L(n)\frac{z^n}{(n!)^{L+1}}, \tag{3}$$

thereby defining a *hypergeometric* generating function for the numbers $b_L(n)$. From eq. (3) it follows formally that

$$ b_L(n)=(n!)^L\cdot\frac{d^n}{dz^n}\left(e^{[\,{}_0F_L(z)-1]}\right)\Big|_{z=0}. \tag{4}$$

For $L=0$ the r.h.s of eq. (4) can be evaluated in closed form:

$$ b_0(n)=\frac{1}{e}\sum_{k=0}^{\infty}\frac{k^n}{k!}=\left\{\frac{1}{e^z}\left[\left(z\frac{d}{dz}\right)^n e^z\right]\right\}_{z=1}. \tag{5}$$

The first equality in (5) is the celebrated Dobiński formula [1], [8], [9]. The second equality in eq. (5) follows from observing that for a power series $R(z)=\sum_{k=0}^{\infty}A_kz^k$ we have

$$ \left(z\frac{d}{dz}\right)^n R(z)=\sum_{k=0}^{\infty}A_k\,k^n\,z^k \tag{6}$$

and applying eq. (6) to the exponential series ($A_k=(k!)^{-1}$).

The reason for including the divisors $(n!)^{L+1}$ rather than $n!$ as in the usual exponential generating function arises from the fact that only by using eq. (3) are the numbers $b_L(n)$ actually integers. This can be seen from general formulas for exponentiation of a power series [8], which employ the (exponential) Bell polynomials, complicated and rather unwieldy objects. It cannot however be considered as a proof that the $b_L(n)$ are integers. At this stage we shall use eq. (3) with $b_L(n)$ real and apply to it an efficient method, described in [9], which will yield the recursion relation for the $b_L(n)$. (For the proof that the $b_L(n)$ are integers, see below eq. (11)). To this end we first obtain a result for the multiplication of two power-series of the type (3). Suppose we wish to multiply $f(x)=\sum_{n=0}^{\infty}a_L(n)\frac{x^n}{(n!)^{L+1}}$ and $g(x)=\sum_{n=0}^{\infty}c_L(n)\frac{x^n}{(n!)^{L+1}}$. We get $f(x)\cdot g(x)=\sum_{n=0}^{\infty}d_L(n)\frac{x^n}{(n!)^{L+1}}$, where

$$ d_L(n)=(n!)^{L+1}\sum_{r+s=n}^{\infty}\frac{a_L(r)c_L(s)}{(r!)^{L+1}(s!)^{L+1}}=\sum_{r=0}^{n}\binom{n}{r}^{L+1}a_L(r)\,c_L(n-r). \tag{7}$$

Substitute eq. (2) into eq. (3) and take the logarithm of both sides of eq. (3):

$$ \sum_{n=1}^{\infty}\frac{z^n}{(n!)^{L+1}}=\ln\left(\sum_{n=0}^{\infty}b_L(n)\frac{z^n}{(n!)^{L+1}}\right). \tag{8}$$

Now differentiate both sides of eq. (8) and multiply by z:

$$\left(\sum_{n=0}^{\infty} b_L(n)\frac{z^n}{(n!)^{L+1}}\right)\left(\sum_{n=0}^{\infty} n\,\frac{z^n}{(n!)^{L+1}}\right) = \sum_{n=0}^{\infty} n\, b_L(n)\frac{z^n}{(n!)^{L+1}}, \tag{9}$$

which with eq. (7) yields the desired recurrence relation

$$b_L(n+1) = \frac{1}{n+1}\sum_{k=0}^{n}\binom{n+1}{k}^{L+1}(n+1-k)\, b_L(k), \qquad n=0,1,\ldots \tag{10}$$

$$= \sum_{k=0}^{n}\binom{n}{k}\binom{n+1}{k}^{L} b_L(k), \tag{11}$$

$$b_L(0) = 1. \tag{12}$$

Since eq. (11) involves only positive integers, it follows that the $b_L(n)$ are indeed positive integers. For $L=0$ one gets the known recurrence relation for the Bell numbers [9]:

$$b_0(n+1) = \sum_{k=0}^{n}\binom{n}{k} b_0(k). \tag{13}$$

We have used eq. (11) to calculate some of the $b_L(n)$'s, listed in Table I, for $L = 0,1,\ldots,6$. Eq.(11), for n fixed, gives closed form expressions for the $b_L(n)$ directly as a function of L (columns in Table I): $b_L(2) = 1+2^L$, $b_L(3) = 1+3\cdot 3^L + (3!)^L$, $b_L(4) = 1+4\cdot 4^L + 3\cdot 6^L + 6\cdot 12^L + (4!)^L$, etc.

The sets of $b_L(n)$ have been checked against the most complete source of integer sequences available [10]. Apart from the case $L=0$ (conventional Bell numbers) only the first non-trivial sequence $L=1$ is listed:[1] it turns out that this sequence $b_1(n)$, listed under the heading A023998 in [10], can be given a combinatorial interpretation as the number of block permutations on a set of n objects which are uniform, i.e. corresponding blocks have the same size [12].

Eq.(1) can be generalized by including an additional variable x, which will result in "smearing out" the conventional Bell numbers $b_0(n)$ with a set of integers $S_0(n,k)$, such that for $k>n$, $S_0(n,k)=0$, and $S_0(0,0)=1$, $S_0(n,0)=0$. In particular,

$$B_0(z,x) \equiv e^{x(e^z-1)} = \sum_{n=0}^{\infty}\left[\sum_{k=1}^{n} S_0(n,k)\, x^k\right]\frac{z^n}{n!}, \tag{14}$$

which leads to the (exponential) generating function of $S_0(n,l)$, the conventional Stirling numbers of the second kind, (see [1], [8]), in the form

$$\frac{(e^z-1)^l}{l!} = \sum_{n=l}^{\infty}\frac{S_0(n,l)}{n!}z^n, \tag{15}$$

and defines the so-called exponential or Touchard polynomials $l_n^{(0)}(x)$ as

$$l_n^{(0)}(x) = \sum_{k=1}^{n} S_0(n,k)x^k. \tag{16}$$

They satisfy

$$l_n^{(0)}(1) = b_0(n), \tag{17}$$

[1] (others have since been added)

justifying the term "smearing out" used above.

The appearance of integers in eq. (3) suggests a natural extension with an additional variable x:

$$B_L(z,x) \equiv e^{x[\,{}_0F_L(z)-1]} = \sum_{n=0}^{\infty} \left[\sum_{k=1}^{n} S_L(n,k)\, x^k \right] \frac{z^n}{(n!)^{L+1}}, \tag{18}$$

where we include the right divisors $(n!)^{L+1}$ in the r.h.s of (18).

This in turn defines "hypergeometric"polynomials of type L and order n through

$$l_n^{(L)}(x) = \sum_{k=1}^{n} S_L(n,k) x^k, \tag{19}$$

which satisfy

$$l_n^{(L)}(1) = b_L(n), \tag{20}$$

with the $b_L(n)$ of eq. (10). Thus the polynomials of eq. (19) "smear out" the $b_L(n)$ with the generalized Stirling numbers of the second kind, of type L, denoted by $S_L(n,k)$ (with $S_L(n,k) = 0$, if $k > n$, $S_L(n,0) = 0$ if $n > 0$ and $S_L(0,0) = 1$), which have, from eq. (18) the "hypergeometric"generating function

$$\frac{({}_0F_L(z)-1)^l}{l!} = \sum_{n=l}^{\infty} \frac{S_L(n,l)}{(n!)^{L+1}}\, z^n, \qquad L = 0,1,2,\ldots. \tag{21}$$

Eq.(21) can be used to derive a recursion relation for the numbers $S_L(n,k)$, in the same manner as eq. (3) yielded eq. (12). Thus we take the logarithm of both sides of eq. (21), differentiate with respect to z, multiply by z and obtain:

$$\left(\sum_{n=0}^{\infty} \frac{S_L(n,l-1)}{(n!)^{L+1}}\, z^n \right) \left(\sum_{n=0}^{\infty} \frac{n}{(n!)^{L+1}}\, z^n \right) = \sum_{n=0}^{\infty} \frac{n\, S_L(n,l)}{(n!)^{L+1}}\, z^n, \tag{22}$$

which, with the help of eq. (7), produces the required recursion relation

$$S_L(n+1,l) = \sum_{k=l-1}^{n} \binom{n}{k} \binom{n+1}{k}^L S_L(k,l-1), \tag{23}$$

$$S_L(0,0) = 1, \qquad S_L(n,0) = 0, \tag{24}$$

which for $L = 0$ is the recursion relation for the conventional Stirling numbers of the second kind [1], [8], and in eq. (23) the appropriate summation range has been inserted. Since the recursions of eq. (23) and eq. (24) involve only integers we conclude that $S_L(n,l)$ are positive integers.

We have calculated some of the numbers $S_L(n,l)$ using eq. (21) and have listed them in Tables II and III, for $L = 1$ and $L = 2$ respectively. Observe that $S_1(n,2) = \binom{2n+1}{n+1} - 1$ and $S_L(n,n) = (n!)^L$, $L = 1,2$. Also, by fixing n and l, the individual values of $S_L(n,l)$ have been calculated as a function of L with the help of eq. (23), see Table IV, from which we observe

$$S_L(n,n) = (n!)^L, \qquad L = 1,2,\ldots. \tag{25}$$

which is the lowest diagonal in Table IV. We now demonstrate that the repetitive use of eq. (23) permits one to establish closed-form expressions for any supra-diagonal of order p, i.e. the sequence $S_L(n+p,n)$,

for $p = 1, 2, 3, \ldots$, if one knows the expression for all $S_L(n+k, n)$ with $k < p$. We shall illustrate it here for $p = 1, 2$. To this end fix $l = n$ on both sides of eq. (23). It becomes, upon using eq. (25), and defining $\alpha_L(n) \equiv S_L(n+1, n)$, a linear recursion relation

$$\alpha_L(n) = \frac{n[(n+1)!]^L}{2^L} + (n+1)^L \alpha_L(n-1), \qquad \alpha_L(0) = 0, \tag{26}$$

with the solution

$$\begin{aligned} \alpha_L(n) = S_L(n+1, n) &= \frac{n(n+1)}{2} \left[\frac{(n+1)!}{2}\right]^L & (27) \\ &= \left[\frac{(n+1)!}{2}\right]^L S_0(n+1, n), & (28) \end{aligned}$$

which gives the second lowest diagonal in Table IV. Observe that for any L, $S_L(n+1, n)$ is proportional to $S_0(n+1, n) = n(n+1)/2$. The sequence $S_1(n+1, n) = 1, 9, 72, 600, 5400, 8564480, \ldots$ is of particular interest: it represents the sum of inversion numbers of all permutations on n letters [10]. For more information about this and related sequences see the entry A001809 in [10]. The $S_L(n+1, n)$ for $L > 1$ do not appear to have a simple combinatorial interpretation. A recurrence equation for $\beta_L(n) \equiv S_L(n+2, n)$ is obtained upon substituting eq. (25) and eq. (27) into eq. (23):

$$\beta_L(n) = \frac{n(n+1)}{2!} \left[\frac{(n+2)!}{2!}\right]^L \left(\frac{n-1}{2^L} + \frac{1}{3^L}\right) + (n+2)^L \beta_L(n-1), \qquad \beta_L(0) = 0. \tag{29}$$

It has the solution

$$S_L(n+2, n) = \frac{n(n+1)(n+2)}{3 \cdot 2^3} \left[\frac{(n+2)!}{2}\right]^L \left(\frac{3}{2^L}(n-1) + \frac{4}{3^L}\right) \tag{30}$$

which is a closed form expression for the second lowest diagonal in Table IV. Clearly, eq. (30) for $L = 0$ gives the combinatorial form for the series of conventional Stirling numbers

$$S_0(n+2, n) = \frac{n(n+1)(n+2)(3n+1)}{4!}. \tag{31}$$

In a similar way we obtain

$$\begin{aligned} S_L(n+3, n) &= \frac{n(n+1)(n+2)(n+3)}{3 \cdot 2^4} \left[\frac{(n+3)!}{3}\right]^L \\ &\quad \times \left(n^2 \left(\frac{3}{8}\right)^L + n\left(\frac{1}{4^{L-1}} - \frac{3^{L+1}}{8^L}\right) + \frac{2 + 2 \cdot 3^L}{8^L} - \frac{1}{4^{L-1}}\right) \end{aligned} \tag{32}$$

which for $L = 0$ reduces to

$$S_0(n+3, n) = \frac{1}{48} n^2 (n+1)^2 (n+2)(n+3). \tag{33}$$

Combined with the standard definition [8], [9]

$$S_0(n, l) = \frac{(-1)^l}{l!} \sum_{k=1}^{l} (-1)^k \left(\begin{array}{c} l \\ k \end{array} \right) k^n. \tag{34}$$

eqs.(28), (31) and (33) give compact expressions for the summation form of $S_0(n+p,n)$. Further, from eq. (34), use of eq. (6) gives the following generating formula

$$S_0(n,l) = \frac{(-1)^l}{l!}\left[\left(z\frac{d}{dz}\right)^n\left(\sum_{k=1}^{l}(-1)^k\left(\begin{array}{c} l \\ k \end{array}\right)z^k\right)\right]_{z=1} \tag{35}$$

$$= \frac{(-1)^l}{l!}\left[\left(z\frac{d}{dz}\right)^n\left[(1-z)^l-1\right]\right]_{z=1}, \qquad n \geq l. \tag{36}$$

The formula (1) can be generalized by putting restrictions on the type of resulting partitions. The generating function for the number of partitions of a set of n distinct elements without singleton blocks $b_0(1,n)$ is [8], [14], [15],

$$B_0(1,z) = e^{e^z-1-z} = \sum_{n=0}^{\infty} b_0(1,n)\frac{z^n}{n!}, \tag{37}$$

or more generally, without singleton, doubleton ..., $p-$blocks ($p = 0, 1, \ldots$) is [15]

$$B_0(p,z) = e^{e^z-\sum_{k=0}^{p}\frac{z^k}{k!}} = \sum_{n=0}^{\infty} b_0(p,n)\frac{z^n}{n!}, \tag{38}$$

with the corresponding associated Stirling numbers defined by analogy with eq. (14) and eq. (22). The numbers $b_0(1,n)$, $b_0(2,n)$, $b_0(3,n)$, $b_0(4,n)$ can be read off from the sequences A000296, A006505, A057837 and A057814 in [10], respectively. For more properties of these numbers see [11].

We carry over this type of extension to eq. (3) and define $b_L(p,n)$ through

$$B_L(p,z) \equiv e^{\,{}_0F_L(z)-\sum_{k=0}^{p}\frac{z^k}{(k!)^{L+1}}} = \sum_{n=0}^{\infty} b_L(p,n)\frac{z^n}{(n!)^{L+1}}, \tag{39}$$

where $b_L(0,n) = b_L(n)$ from eq. (3). (We know of no combinatorial meaning of $b_L(p,n)$ for $L \geq 1$, $p > 0$). The $b_L(p,n)$ satisfy the following recursion relations:

$$b_L(p,n) = \sum_{k=0}^{n-p}\left(\begin{array}{c} n \\ k \end{array}\right)\left(\begin{array}{c} n+1 \\ k \end{array}\right)^L b_L(p,k), \tag{40}$$

$$b_L(p,0) = 1, \tag{41}$$

$$b_L(p,1) = b_L(p,2) = \cdots = b_L(p,p) = 0, \tag{42}$$

$$b_L(p,p+1) = 1. \tag{43}$$

That the $b_L(p,n)$ are integers follows from eq. (40). Through eq. (39) additional families of integer Stirling-like numbers $S_{L,p}(n,k)$ can be readily defined and investigated.

The numbers $b_0(p,n)$ are collected in Table V, and Tables VI and VII contain the lowest values of $b_1(p,n)$ and $b_2(p,n)$, respectively.

Formula (1) can be used to express e in terms of $b_0(n)$ in various ways. Two such lowest order (in differentiation) forms are

$$e = 1 + \ln\left(\sum_{n=0}^{\infty}\frac{b_0(n)}{n!}\right) = \tag{44}$$

$$= \ln\left(\sum_{n=0}^{\infty}\frac{b_0(n+1)}{n!}\right). \tag{45}$$

In the very same way, eq. (3) can be used to express the values of ${}_0F_L(z)$ and its derivatives at $z = 1$ in terms of certain series of $b_L(n)$'s. For $L = 1$, the analogues of eq. (44) and eq. (45) are

$$I_0(2) = 1 + \ln\left(\sum_{n=0}^{\infty} \frac{b_1(n)}{(n!)^2}\right), \tag{46}$$

$$I_0(2) + \ln(I_1(2)) = 1 + \ln\left(\sum_{n=0}^{\infty} \frac{b_1(n+1)}{(n+1)(n!)^2}\right) \tag{47}$$

and for $L = 2$ the corresponding formulas are

$${}_0F_2(1,1;1) = 1 + \ln\left(\sum_{n=0}^{\infty} \frac{b_2(n)}{(n!)^3}\right), \tag{48}$$

$${}_0F_2(1,1;1) + \ln\left({}_0F_2(2,2;1)\right) = 1 + \ln\left(\sum_{n=0}^{\infty} \frac{b_2(n+1)}{(n+1)^2(n!)^3}\right). \tag{49}$$

By fixing z_0 at values other than $z_0 = 1$, one can link the numerical values of certain combinations of ${}_0F_L(1,1,\ldots;z_0)$, ${}_0F_L(2,2,\ldots;z_0)$,... and their logarithms, with other series containing the $b_L(n)$'s.

The above considerations can be extended to the exponentiation of the more general hypergeometric functions of type ${}_0F_L(k_1,k_2,\ldots,k_L;z)$ where $k_1,k_2,\ldots,k_L$ are positive integers. We conjecture that for every set of k_n's a different set of integers will be generated through an appropriate adaptation of eq. (3). We quote one simple example of such a series. For

$${}_0F_2(1,2;z) = \sum_{n=0}^{\infty} \frac{z^n}{(n+1)(n!)^3} \tag{50}$$

eq. (3) extends to

$$e^{[\,{}_0F_2(1,2;z)-1]} = \sum_{n=0}^{\infty} f_2(n) \frac{z^n}{(n+1)(n!)^3} \tag{51}$$

where the numbers

$$f_2(n) = (n+1)(n!)^2 \left[\frac{d^n}{dz^n} e^{[\,{}_0F_2(1,2;z)-1]}\right]_{z=0} \tag{52}$$

turn out to be integers: $f_2(n)$, $n = 0,1,\ldots,8$ are: 1, 1, 4, 37, 641, 18276, 789377, 48681011, etc. (A061683). The analogue of equations (23) and (44) is:

$${}_0F_2(1,2;1) = 1 + \ln\left(\sum_{n=0}^{\infty} \frac{f_2(n)}{(n+1)(n!)^3}\right). \tag{53}$$

Acknowledgements

We thank L. Haddad for interesting discussions. We have used Maple© to calculate most of the numbers discussed above.

Abstract

The Hankel transform of an integer sequence is defined and some of its properties discussed. It is shown that the Hankel transform of a sequence S is the same as the Hankel transform of the Binomial or Invert transform of S. If H is the Hankel matrix of a sequence and H=LU is the LU decomposition of H, the behavior of the first super-diagonal of U under the Binomial or Invert transform is also studied. This leads to a simple classification scheme for certain integer sequences.

1. Introduction.

The Hankel matrix H of the integer sequence $\{a_1, a_2, a_3, \cdots\}$ is the infinite matrix

$$H = \begin{bmatrix} a_1 & a_2 & a_3 & a_4 & \cdots \\ a_2 & a_3 & a_4 & a_5 & \cdots \\ a_3 & a_4 & a_5 & a_6 & \cdots \\ a_4 & a_5 & a_6 & a_7 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix},$$

with elements $h_{i,j} = a_{i+j-1}$. The *Hankel matrix* H_n *of order n* of A is the upper-left n×n submatrix of H, and h_n, the *Hankel determinant of order n* of A, is the determinant of the corresponding Hankel matrix of order n, $h_n = \det(H_n)$. For example, the Hankel matrix of

order 4 of the Fibonacci sequence 1,1,2,3,5,… , is

$$H_4 = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 1 & 2 & 3 & 5 \\ 2 & 3 & 5 & 8 \\ 3 & 5 & 8 & 13 \end{bmatrix},$$

with 4th order Hankel determinant $h_4 = 0$. Hankel matrices of integer sequences and their determinants have been studied in several recent papers by Ehrenborg [1] and Peart and Woan [2].

Given an integer sequence $A = \{a_1, a_2, a_3, \cdots\}$, the sequence $\{h_n\} = \{h_1, h_2, h_3, \cdots\}$ of Hankel determinants of A is called the *Hankel transform of A*, a term first introduced by the author in sequence A055878 of the On-Line Encyclopedia of Integer Sequences (EIS)[5]. For example, the Hankel matrix of order 4 of the sequence of Catalan numbers $\{1, 1, 2, 5, 14, 42, 132, \cdots\}$ (sequence A000108 in the EIS) is

$$H_4 = \begin{bmatrix} 1 & 1 & 2 & 5 \\ 1 & 2 & 5 & 14 \\ 2 & 5 & 14 & 42 \\ 5 & 14 & 42 & 132 \end{bmatrix},$$

and the determinants of orders 1 through 4 give the Hankel transform $\{1,1,1,1,\ldots\}$.

The Hankel transform can easily be shown to be many-to-one, illustrated by the fact that a search of the EIS finds approximately twenty sequences besides A000108 that have the Hankel transform $\{1,1,1,1,\ldots\}$. The author and Michael Somos [6], working independently, found ten sequences in the EIS whose Hankel transform is $\{\prod_{i=0}^{n} (i!)^2\}$ (A055209), which was shown theoretically by Radoux [3] to be the Hankel transform of the *derangement*, or *rencontres*, numbers (A000166). Other examples of groups of sequences in the EIS all of which have the same Hankel transform may be found in the comments to sequences A000079 and A000178.

2. Invariance of the Hankel Transform.

Further computational investigation reveals numerous instances in which one member of a pair of sequences with the same Hankel transform is the Binomial or Invert transform of the other. Some examples are provided by A000166 and its Binomial transform A000142,

both of which have the Hankel transform A055209, and by A005043 and its Invert transform A001006, both of which have {1, 1, 1, 1, …} for their Hankel transform. In the following it is shown that this invariance of the Hankel transform under applications of the Binomial or Invert transform holds in general. The definitions of the Binomial and Invert transforms may be found on the EIS web site [5].

Theorem 1. *Let A be an integer sequence and B its Binomial transform. Then A and B have the same Hankel transform.*

Proof. Let $A = \{a_1, a_2, a_3, \cdots\}$ and $B = \{b_1, b_2, b_3, \cdots\}$, and define H* to be the matrix H* = RHC, where the elements of R, H, and C are given by

$$r_{i,j} = \begin{cases} 0, & \text{if } i < j, \\ \binom{i-1}{j-1}, & \text{if } i \geq j \end{cases}, \quad h_{k,m} = a_{k+m-1}, \quad \text{and} \quad c_{i,j} = \begin{cases} 0, & \text{if } i > j, \\ \binom{j-1}{i-1}, & \text{if } i \leq j \end{cases},$$

and $\binom{i}{j}$ denotes the usual binomial coefficient. Then the elements of H* are

$$h^*_{i,j} = \sum_{k=1}^{i} \sum_{m=1}^{j} \binom{i-1}{k-1} a_{k+m-1} \binom{j-1}{m-1},$$

which, by making slight changes of variables, gives

$$h^*_{i,j} = \sum_{k=0}^{i-1} \sum_{m=0}^{j-1} \binom{i-1}{k} \binom{j-1}{m} a_{k+m-1}.$$

By the well-known Vandermonde convolution formula [4] and another slight change of variable, this reduces to

$$h^*_{i,j} = \sum_{s=1}^{i+j-1} \binom{i+j-2}{s-1} a_s,$$

which, by the definition of the Binomial transform (see [5]), is b_{i+j-1}, thus showing that H* is the Hankel matrix of sequence B. Thus the terms of the Hankel transforms of the sequences A and B are det(H_n) and det($R_n H_n C_n$), respectively, where R_n, H_n, and C_n are the upper-left submatrices of order n of H, R, and C, respectively. But R_n and C_n are

both triangular with all 1's on the main diagonal, thus det(R_n) and det(C_n) are both 1, and therefore det(H_n) = det($R_n H_n C_n$), completing the proof. ∎

Theorem 2. *Let A be an integer sequence and B its Invert transform. Then A and B have the same Hankel transform.*

Proof. Let $A = \{a_1, a_2, a_3, \cdots\}$ and $B = \{b_1, b_2, b_3, \cdots\}$, and define H* to be the matrix H*=RHC, where the elements of R, H, and C are given by

$$r_{i,k} = \begin{cases} 0, & \text{if } k > i, \\ b_{i-k}, & \text{if } k \le i \end{cases}, \quad h_{k,m} = a_{k+m-1}, \quad \text{and } c_{m,j} = \begin{cases} 0, & \text{if } j < m, \\ b_{j-m}, & \text{if } j \ge m \end{cases},$$

where b_0 is defined to be 1. Then the (i, j-1)-element of H* given by

$$\begin{aligned} h^*_{i,j-1} &= \sum_{k=1}^{i} \sum_{m=1}^{j-1} b_{i-k}\, a_{k+m-1}\, b_{j-m-1} \\ &= \sum_{k=2}^{i} \sum_{m=1}^{j-1} b_{i-k}\, a_{k+m-1}\, b_{j-m-1} + b_{i-1} \sum_{m=1}^{j-1} a_m\, b_{j-m-1} \\ &= \sum_{k=1}^{i-1} \sum_{m=1}^{j-1} b_{i-1-k}\, a_{k+m}\, b_{j-m-1} + b_{i-1}\left[\sum_{m=1}^{j-2} a_m\, b_{j-m-1} + a_{j-1}\right] \\ &= \sum_{k=1}^{i-1} \sum_{m=2}^{j} b_{i-1-k}\, a_{k+m-1}\, b_{j-m} + b_{i-1} b_{j-1} \\ &= \sum_{k=1}^{i-1} \sum_{m=1}^{j} b_{i-1-k}\, a_{k+m-1}\, b_{j-m} + b_{j-1} \sum_{k=1}^{i-1} b_{i-1-k}\, a_k + b_{i-1} b_{j-1} \\ &= h^*_{i-1,j}\ , \end{aligned}$$

showing that elements of H* are constant along anti-diagonals. But, clearly,

$$\begin{aligned} h^*_{1,j} &= \sum_{k=1}^{1} \sum_{m=1}^{j} b_{1-k}\, a_{k+m-1}\, b_{j-m} \\ &= b_0 \sum_{m=1}^{j} a_m b_{j-m} \\ &= b_j\ , \end{aligned}$$

the last step following from the definition of the Invert transform (see [5]), which shows that $h^*_{i,j} = b_{i+j-1}$ or, in other words, that H* is the Hankel matrix of B. Since L and R are triangular with diagonals consisting of all 1's, this shows that the Hankel determinants of B are the same as those for A, and thus A and B have the same Hankel transform. ∎

3. The LU Decomposition and the First Super-Diagonal.

If the LU-decomposition of the Hankel matrix of an integer sequence A is H = LU, then the main diagonal of U clearly determines the Hankel transform of the sequence, and vice versa. By Theorem 1, if H* = L*U* is the LU-decomposition of the Hankel matrix H* of the Binomial or Invert transform of A, then the main diagonals of U and U* are identical. Thus the main diagonal of U is not sufficient to determine the sequence A, a point already noted. It is easy to see, however, that the main diagonal of U and the first superdiagonal, taken together, do determine A. It suffices to note, in proof, that H_n, the Hankel matrix of order n, consists of the first 2n-1 terms $a_1, a_2, a_3, \cdots$ of A and that the main diagonal and first superdiagonal of U_n contain 2n-1 elements whose values are linear combinations of the a's. Thus, $U_{1,1}$ determines a_1, $U_{1,2}$ and $U_{2,2}$ determine a_2 and a_3, and, by recursion, $U_{n-1,n}$ and $U_{n,n}$ determine a_{2n-2} and a_{2n-1}.

Because of the result just stated, it is of some interest to know how the first superdiagonal of U* is related to the first superdiagonal of U, where H=LU and H*=L*U*. The following two theorems give this relationship when A* is the Binomial transform or Invert transform of A.

Theorem 3. *Let H and H* be the Hankel matrices of the integer sequence A and its Binomial transform A*, respectively, and let H=LU and H*=L*U* be their LU-decompositions. Then the first super-diagonals of U and U* are related by* $U^*_{i,i+1} = U_{i,i+1} + iU_{i,i}$.

Proof. We have H = LU and, by the proof of the previous theorem, H* = RHC = RLUC, where the matrices R and C are as defined in that theorem. Thus U* = UC or, in terms of elements,

$$U^*_{i,j} = \sum_{k=1}^{j} U_{i,k} \binom{j-1}{k-1},$$

which, since $U_{i,k}$ is upper triangular, can be written

$$U^*_{i,j} = \sum_{k=i}^{j} U_{i,k} \binom{j-1}{k-1}.$$

The elements on the first super-diagonal are therefore given by

$$U^*_{i,i+1} = U_{i,i}\binom{i}{i-1} + U_{i,i+1}\binom{i}{i},$$

which reduces immediately to

$$U^*_{i,i+1} = U_{i,i+1} + iU_{i,i},$$

as was to be proved. ∎

A special case, which is of some interest because of a fairly large number of examples found in the EIS, follows immediately and is stated in the following corollary.

Corollary 1. *Let A be an integer sequence with Hankel transform {1, 1, 1, 1, 1, …} and let H and H* be the Hankel matrices of A and its Binomial transform A*, respectively. Then, if H=LU and H*=L*U* are the LU-decompositions of H and H*, the first superdiagonals of U and U* are related by* $U^*_{i,i+1} = U_{i,i} + i$.

The analogous results for the Hankel matrix of the Invert transform of a sequence follow.

Theorem 4. *Let A be an integer sequence, with Hankel matrix H, and let B be the Invert transform of A, with Hankel transform H*. Let H=LU be the LU-decomposition of H and H*=L*U* the LU-decomposition of H*. Then the elements of the first superdiagonals of U and U* are related by* $u^*_{i,i+1} = u_{i,i+1} + a_1 u_{i,i}$.

Proof. Let the matrices R and C be as in the proof of Theorem 3. Then H* = L*U* = RHC =RLUC, from which it follows that U* = UC. Thus we have, in general,

$$u^*_{i,j} = \sum_{m=i}^{j} u_{i,m}\, b_{j-m},$$

and, in particular,

$$\begin{aligned} u^*_{i,i+1} &= \sum_{m=i}^{i+1} u_{i,m}\, b_{i+1-m} \\ &= u_{i,i}\, b_1 + u_{i,i+1}\, b_0 \\ &= u_{i,i+1} + a_1\, u_{i,i}\ , \end{aligned}$$

completing the proof. ∎

Again, because of the large number of sequences in the EIS with Hankel transform {1, 1, 1, 1, 1, …}, we state the following corollary.

Corollary 2. *Let A be an integer sequence with Hankel transform {1, 1, 1, 1, 1, …} and let H and H* be the Hankel matrices of A and its Invert transform A*, respectively. Then, if H=LU and H*=L*U* are the LU-decompositions of H and H*, the first superdiagonals of U and U* are related by* $U^*_{i,i+1} = U_{i,i} + 1$.

4. Sequences with Hankel Transform {1, 1, 1, 1, 1, …}.

A search of the EIS database found almost twenty sequences with Hankel transform {1, 1, 1, 1, 1, …}, of which seventeen are related through the Binomial and Invert transforms. In a few cases an initial term or two must be added or deleted. It is rather surprising that all of these sequences exhibit a linear polynomial behavior of the first super-diagonal when reduced to upper triangular form. Table 1 below illustrates the relationships among these 17 sequences. Each sequence in the table is the Binomial transform of the sequence in the adjacent column to its left and the Invert transform of the sequence in the adjacent row just above the given entry. The linear polynomial written just below the EIS sequence number gives the elements of the first super-diagonal of U in the LU decomposition H=LU, where H is the Hankel matrix of the sequence. The parameter i is the row index of U. The operator (E) denotes the shift operator and is used here to denote the deletion of the first term of the sequence. Added initial terms are shown in braces.

Note that, because of Corollaries 1 and 2 governing the behavior of the elements of the first superdiagonal under the action of the Binomial or Invert transforms, the constant terms increase by 1 for each row change from top to bottom and the first degree coefficient increases by 1 for each column change from left to right. In one case, in the bottom row, in which the first superdiagonal is described by the polynomial i+2, the sequence, which is the Binomial transform of A054341 and the Invert transform of (E)A005773 and whose initial terms are {1,3,10,34,117, …}, was not found to be listed in the EIS. It has since been listed, and now appears in the encyclopedia as sequence A059738.

Table 1.

		{1,0} ⋃ A000957 2i - 2	A033321 3i - 2	A033543 4i - 2
	A005043 i - 1	A000108 2i - 1	A007317 3i - 1	
	A001006 I	(E)A000108 2i	A002212 3i	A005572 4i
A001405 1	(E)A005773 i + 1	A001700 2i + 1	A026378 3i + 1	A005573 4i + 1
A054341 2	{1,3,10,34,117, …} i + 2	A049027 2i + 2		

In order to illustrate the significance of this table, we look at A000108 (the Catalan numbers, with many combinatorial interpretations, one of which is the number of ways to insert n pairs of parentheses in a word of n letters) in row 2 and column 3 of the table. The sequence is {1, 1, 2, 5, 14, 42, 132, 429, 1430,…}, with Hankel matrix

$$\begin{bmatrix} 1 & 1 & 2 & 5 & 14 & \cdots \\ 1 & 2 & 5 & 14 & 42 & \cdots \\ 2 & 5 & 14 & 42 & 132 & \cdots \\ 5 & 14 & 42 & 132 & 429 & \cdots \\ 14 & 42 & 132 & 429 & 1430 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix},$$

which row-reduces to the upper-triangular form

$$U = \begin{bmatrix} 1 & 1 & 2 & 5 & 14 \\ 0 & 1 & 3 & 9 & 28 \\ 0 & 0 & 1 & 5 & 24 \\ 0 & 0 & 0 & 1 & 7 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

which clearly exhibits the Hankel transform of {1, 1, 1, 1, 1, …} and the 2i-1 polynomial behavior of the first super-diagonal {1, 3, 5, 7, …}, as indicated in the table. If we now take the Binomial transform of A000108, we get {1, 2, 5, 15, 51, 188, 731, …} = A007317, with Hankel matrix

$$\begin{bmatrix} 1 & 2 & 5 & 15 & 51 \\ 2 & 5 & 15 & 51 & 188 \\ 5 & 15 & 51 & 188 & 731 \\ 15 & 51 & 188 & 731 & 2950 \\ 51 & 188 & 731 & 2950 & 12235 \end{bmatrix},$$

which, in turn reduces to the upper-triangular form

$$U = \begin{bmatrix} 1 & 2 & 5 & 15 & 51 \\ 0 & 1 & 5 & 21 & 86 \\ 0 & 0 & 1 & 8 & 46 \\ 0 & 0 & 0 & 1 & 11 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

showing the Hankel transform {1, 1, 1, 1, 1, …} and the first super-diagonal {2, 5, 8, 11, …} = {3i-1}, again in agreement with the table.

If we now return to A000108 and take its Invert transform, we get (E)A000108 = {1, 2, 5, 14, 42, 132, 429, 1430, 4862, …}, that is, A000108 with the first term deleted. The Hankel matrix of this sequence row-reduces to

$$U = \begin{bmatrix} 1 & 2 & 5 & 14 & 42 \\ 0 & 1 & 4 & 14 & 48 \\ 0 & 0 & 1 & 6 & 27 \\ 0 & 0 & 0 & 1 & 8 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

again revealing the Hankel transform {1, 1, 1, 1, 1, …} and the polynomial behavior of 2i for the first super-diagonal, {2, 4, 6, 8, …}, in agreement with row 3, column 3 of the table.

Three other sequences have been found in the EIS which have the Hankel transform {1, 1, 1, 1, 1, …} but do not have a linear polynomial behavior of the first super-diagonal when reduced to upper-triangular form. These are A054391, A054393, and A055879, with first super-diagonals {1, 3, 4, 5, 6, …}, {1, 3, 5, 6, 7, …}, and {1, 2, 2, 3, 3, 4, 4, …}, respectively.

5. Other Families of Sequences.

Several other families of sequences, each member of which has the same Hankel transform sequence, have been found in the EIS, but the relationships among the members of the family via the Binomial and Invert transforms is much less complete than that indicated in Table 1 for the case of Hankel transform {1, 1, 1, 1, 1, …}.

Seven sequences have been found with Hankel transform {1, 2, 4, 8, 16, …}: A000984, A002426, A026375, A026569, A026585, and A026671. Four of these are related by the Binomial and Invert transforms, as shown in the following Table 2 in which each sequence listed is the Binomial transform of the sequence just to the left and the Invert transform of the sequence just above.

Table 2.

A002426	A000984	A026375
	A026671	

Seven sequences were found with Hankel transform {1, 1, 2, 12, 288, …}: A000085, A000110, A000296, A005425, A005493, A005494, and A045379. These are all related to at

least one other by the Binomial transform, as shown in Table 3, in which each sequence is the Binomial transform of the sequence just to its left. No Invert transform relations hold among adjacent rows.

Table 3.

A000296	A000110	(E)A000110	A005493	A005494	A045379

A000085	A005425

Several of the sequences listed above, with Hankel transform {1, 1, 2, 12, 288, …}, as well as some of those below, with Hankel transform {1, 1, 4, 144, 82944, …}, were discussed by Ehrenborg in [1].

Nine sequences were found with Hankel transform {1, 1, 4, 144, 82944, …}: A000142, A000166, A000522, A003701, A010483, A010842, A052186, A053486, and A053487. Seven of these are related to at least one other by the Binomial or Invert transform. Table 4 shows these relationships, following the same format as used for Table 1.

Table 4.

6. Concluding Remarks.

Among questions raised by this investigation into properties of the Hankel transform we mention two which seem to be deserving of further study.

First, is there a combinatorial significance to the fact that essentially all studied sequences listed in the EIS [5] that have the Hankel transform {1, 1, 1, 1,…} and are related by the Binomial or Invert transform, have a first super-diagonal which, when reduced to upper-diagonal form, is linear in the row index with small coefficients, with constant terms ranging from -2 to 2 and first degree terms ranging from 0 to 4, as shown in Table 1?

Second, are there other interesting transforms, T, of an integer sequence S, in addition to the Binomial and Invert transforms studied in this paper, with the property that the Hankel transform of S is the same as the Hankel transform of the T transform of S?

Abstract

In this paper we investigate some algorithms which produce Bernoulli numbers, Euler numbers, and tangent numbers. We also give closed formulae for Euler numbers and tangent numbers in terms of Stirling numbers of the second kind.

1991 *Mathematics Subject Classification.* Primary 11B68

Keywords. Bernoulli number, Euler number, Euler polynomial, Stirling number of the second kind, tangent number

1. Introduction

Recently M. Kaneko (ref. [4]) reformulated Akiyama and Tanigawa's algorithm for computing Bernoulli numbers as follows:

Proposition 1 (ref. [4]). *Given an initial sequence $a_{0,m}$ $(m = 0, 1, 2, \cdots)$, define sequences $a_{n,m}$ $(n \geq 1)$ recursively by*

$$a_{n,m} = (m+1) \cdot (a_{n-1,m} - a_{n-1,m+1}) \qquad (n \geq 1, m \geq 0).$$

Then the leading elements are given by

$$a_{n,0} = \sum_{m=0}^{n} (-1)^m m! \left\{ {n+1 \atop m+1} \right\} a_{0,m}, \tag{1}$$

where the Stirling numbers of the second kind $\left\{ {n \atop m} \right\}$ are defined by

$$\frac{(e^x - 1)^m}{m!} = \sum_{n=m}^{\infty} \left\{ {n \atop m} \right\} \frac{x^n}{n!}.$$

Suppose the initial sequence is $a_{0,m} = 1/(m+1)$. Then the Akiyama and Tanigawa algorithm is the following. Begin with the 0-th row 1, 1/2, 1/3, 1/4, 1/5, 1/6, $\cdots$ The recursive rule gives the first row $1\cdot(1-1/2)$, $2\cdot(1/2-1/3)$, $3\cdot(1/3-1/4)$, $4\cdot(1/4-1/5)$, $\cdots$ which is 1/2, 1/3, 1/4, 1/5, $\cdots$. The 2nd row is given by $1\cdot(1/2-1/3)$, $2\cdot(1/3-1/4)$, $3\cdot(1/4-1/5)$, $\cdots$, etc. The Akiyama-Tanigawa matrix $a_{n,m}$ is then

1	1/2	1/3	1/4	1/5	1/6	1/7	1/8	1/9	1/10	1/11	...
1/2	1/3	1/4	1/5	1/6	1/7	1/8	1/9	1/10	1/11	...	
1/6	1/6	3/20	2/15	5/42	3/28	7/72	4/45	9/110	...		
0	1/30	1/20	2/35	5/84	5/84	7/120	28/495	...			
−1/30	−1/30	−3/140	−1/1050		1/140	49/3960	..				
0	−1/42	−1/28	−4/105	−1/28	−29/924	.					
1/42	1/42	1/140	−1/105	−5/231	...						
0	1/30	1/20	8/165	...							
−1/30	−1/30	1/220	...								
0	−5/66	...									
5/66	...										
...											

M. Kaneko [4] gave a direct proof that the leading element $a_{n,0}$ in the above array is $B_n(1)$, where the Bernoulli polynomials $B_n(x)$ are defined by

$$\frac{te^{xt}}{e^t-1} = \sum_{n=0}^{\infty} \frac{B_n(x)t^n}{n!}.$$

Note that Bernoulli numbers B_n can be defined as $B_n(0)$.

In the sequel we denote the above algorithm as the A-algorithm. Let us change the recursive step in the A-algorithm to

$$a_{n,m} = m\cdot a_{n-1,m} - (m+1)\cdot a_{n-1,m+1} \qquad (n\geq 1, m\geq 0).$$

Proposition 2. *Given an initial sequence $a_{0,m}$ $(m = 0,1,2,\cdots)$, define the sequences $a_{n,m}$ $(n\geq 1)$ recursively by*

$$a_{n,m} = m\cdot a_{n-1,m} - (m+1)\cdot a_{n-1,m+1}, \qquad (n\geq 1, m\geq 0). \tag{2}$$

Then

$$a_{n,0} = \sum_{m=0}^{n} (-1)^m m! \left\{ {n \atop m} \right\} a_{0,m}. \tag{3}$$

We call the algorithm in Proposition 2 the B-algorithm. If we again start with the initial sequence $a_{0,m} = 1/(m+1)$, then (cf. Eq. (6.99) or p. 560 of [2])

$$a_{n,0} = \sum_{m=0}^{n} \frac{(-1)^m m! \left\{ {n \atop m} \right\}}{m+1} = B_n = B_n(0).$$

In fact, we have the following theorem:

Theorem 1. *Suppose the initial sequence* $a_{0,m}$ $(m = 0, 1, 2, \cdots)$ *has the ordinary generating function*

$$A(x) = \sum_{m=0}^{\infty} a_{0,m} x^m.$$

Then the leading elements $a_{n,0}$ $(n = 0, 1, 2, \dots)$ *have exponential generating function*

$$B(x) = \sum_{n=0}^{\infty} a_{n,0} \frac{x^n}{n!}$$

given by $e^x A(1 - e^x)$ *for the A-algorithm and* $A(1 - e^x)$ *for the B-algorithm.*

Consider now the initial sequence $a_{0,m} = 1/2^m$ in the A-algorithm and B-algorithm, respectively. We obtain the leading elements $a_{n,0}$ as $E_n(1)$ and $E_n(0)$, respectively, where the Euler polynomials $E_n(x)$ are defined by

$$\frac{2e^{xt}}{e^t + 1} = \sum_{n=0}^{\infty} \frac{E_n(x) t^n}{n!}.$$

Note that the Euler numbers E_n can be defined as $2^n E_n(1/2)$. Alternatively we may define the Euler numbers by

$$\sec x = \sum_{n=0}^{\infty} \frac{(-1)^n E_{2n}}{(2n)!} x^{2n}.$$

They are closely related to the tangent numbers T_n (cf. [3]), which are defined by

$$\tan x = \sum_{n=0}^{\infty} \frac{(-1)^{n+1} T_{2n+1}}{(2n+1)!} x^{2n+1}, \qquad T_0 = 1.$$

Moreover, if we take the initial sequence to be

$$a_{0,m} = (-1)^{[m/4]} \cdot 2^{-[m/2]} \cdot (1 - \delta_{4,m+1}), \qquad \text{where } \delta_{4,i} = \begin{cases} 1, & \text{if } \ 4|i, \\ 0, & \text{otherwise.} \end{cases}$$

in the A-algorithm and B-algorithm, respectively, the leading elements $a_{n,0}$ become E_n and T_n, respectively. We now give the proof of the above statements.

2. Proof of Proposition 2 and Theorem 1

To prove Proposition 2, we use a similar trick to that used in the proof of Proposition 2 in [4]. Put

$$g_n(t) = \sum_{m=0}^{\infty} a_{n,m} t^m.$$

By the recursion Eq.(2) we have for $n \geq 1$

$$\begin{aligned} g_n(t) &= \sum_{m=0}^{\infty}(m \cdot a_{n-1,m} - (m+1) \cdot a_{n-1,m+1})t^m \\ &= \sum_{m=0}^{\infty}(m+1)a_{n-1,m+1}t^{m+1} - \sum_{m=0}^{\infty}(m+1)a_{n-1,m+1}t^m \\ &= (t-1)\sum_{m=0}^{\infty}(m+1)a_{n-1,m+1}t^m \\ &= (t-1)\frac{d}{dt}g_{n-1}(t) \;=\; \left((t-1)\frac{d}{dt}\right)^n g_0(t). \end{aligned}$$

Using the recursion for the Stirling numbers of second kind

$$\left\{ {n+1 \atop m+1} \right\} = (m+1)\left\{ {n \atop m+1} \right\} + \left\{ {n \atop m} \right\},$$

and mathematical induction on n, we have (ref. p. 310 in [2])

$$\left((t-1)\frac{d}{dt}\right)^n = \sum_{m=0}^{n}\left\{ {n \atop m} \right\}(t-1)^m \left(\frac{d}{dt}\right)^m.$$

Therefore

$$g_n(t) = \sum_{m=0}^{n}\left\{ {n \atop m} \right\}(t-1)^m \left(\frac{d}{dt}\right)^m g_0(t).$$

Setting $t = 0$ we get the assertion of Proposition 2

$$a_{n,0} = \sum_{m=0}^{n}\left\{ {n \atop m} \right\}(-1)^m m! a_{0,m}. \quad \square$$

Now we give the proof of Theorem 1. In the A-algorithm we use the identity which appeared in Eq. (3) of [4]:

$$\frac{e^x(e^x-1)^m}{m!} = \sum_{n=m}^{\infty}\left\{ {n+1 \atop m+1} \right\}\frac{x^n}{n!},$$

and Eq.(1). Then the exponential generating function for the leading elements $a_{n,0}$ is

$$\begin{aligned} B(x) = \sum_{n=0}^{\infty} a_{n,0}\frac{x^n}{n!} &= \sum_{n=0}^{\infty}\left(\sum_{m=0}^{n}(-1)^m m!\left\{ {n+1 \atop m+1} \right\}a_{0,m}\right)\frac{x^n}{n!} \\ &= \sum_{m=0}^{\infty}(-1)^m m! a_{0,m}\sum_{n=m}^{\infty}\left\{ {n+1 \atop m+1} \right\}\frac{x^n}{n!} \\ &= \sum_{m=0}^{\infty}(-1)^m m! a_{0,m}\frac{e^x(e^x-1)^m}{m!} \\ &= e^x\sum_{m=0}^{\infty}(1-e^x)^m a_{0,m} \;=\; e^x A(1-e^x). \end{aligned}$$

Next we treat the B-algorithm case. Using Eq.(3) we have

$$\begin{aligned} B(x) = \sum_{n=0}^{\infty} a_{n,0}\frac{x^n}{n!} &= \sum_{n=0}^{\infty}\left(\sum_{m=0}^{n}(-1)^m m!\left\{{n \atop m}\right\}a_{0,m}\right)\frac{x^n}{n!} \\ &= \sum_{m=0}^{\infty}(-1)^m m! a_{0,m}\sum_{n=m}^{\infty}\left\{{n \atop m}\right\}\frac{x^n}{n!} \\ &= \sum_{m=0}^{\infty}(-1)^m m! a_{0,m}\frac{(e^x-1)^m}{m!} \\ &= \sum_{m=0}^{\infty}(1-e^x)^m a_{0,m} \;=\; A(1-e^x). \end{aligned}$$

This completes the proof of Theorem 1. □

3. Euler numbers and Tangent numbers

Theorem 2. *Set $a_{0,m} = 1/2^m$ for $m \geq 0$ in the A-algorithm and B-algorithm. Then the leading elements $a_{n,0}$ for $n \geq 0$ are given by $E_n(1)$ and $E_n(0)$, respectively.*

Proof. In the B-algorithm,

$$\begin{aligned} A(1-e^x) &= \sum_{m=0}^{\infty}(1-e^x)^m a_{0,m} \\ &= \sum_{m=0}^{\infty}\left(\frac{1-e^x}{2}\right)^m \;=\; \frac{2}{e^x+1}. \end{aligned}$$

The exponential generating functions for $E_n(0)$ and $E_n(1)$ are $2/(e^x+1)$ and $2e^x/(e^x+1)$, respectively. Using Theorem 1 completes the proof. □

Theorem 3. *Set*

$$a_{0,m} = (-1)^{[m/4]}\cdot 2^{-[m/2]}\cdot(1-\delta_{4,m+1}), \qquad \textit{where } \delta_{4,i} = \begin{cases} 1, & \textit{if} \quad 4|i, \\ 0, & \textit{otherwise,} \end{cases}$$

in the A-algorithm and B-algorithm. Then the leading elements $a_{n,0}$ are E_n and T_n, respectively.

Proof. The exponential generating functions for E_n and T_n are $2e^x/(e^{2x}+1)$ and $2/(e^{2x}+1)$, respectively. From the results of Theorem 1, we only need to prove that $A(1-e^x) = 2/(e^{2x}+1)$ in the B-algorithm. We have

$$\begin{aligned} A(1-e^x) &= \sum_{m=0}^{\infty}(1-e^x)^m a_{0,m} \\ &= \sum_{k=0}^{\infty}\frac{(-1)^k(1-e^x)^{4k}}{2^{2k}} + \sum_{k=0}^{\infty}\frac{(-1)^k(1-e^x)^{4k+1}}{2^{2k}} + \sum_{k=0}^{\infty}\frac{(-1)^k(1-e^x)^{4k+2}}{2^{2k+1}}. \end{aligned}$$

∎

Let

$$D(x) = \sum_{k=0}^{\infty} \frac{(-1)^k (1-e^x)^{4k}}{2^{2k}} = \frac{4}{(e^{2x}-4e^x+5)(e^{2x}+1)}.$$

Then

$$\begin{aligned} A(1-e^x) &= D(x) + (1-e^x)D(x) + \frac{(1-e^x)^2}{2} D(x) \\ &= D(x) \cdot (1+1-e^x + \frac{1-2e^x+e^{2x}}{2}) \\ &= \frac{4}{(e^{2x}-4e^x+5)(e^{2x}+1)} \cdot \frac{e^{2x}-4e^x+5}{2} \;=\; \frac{2}{e^{2x}+1}. \end{aligned}$$

This completes the proof. □

The following is the matrix generated by Theorem 3 for the Euler numbers E_n:

1 1 1/2 0 -1/4 -1/4 -1/8 0 1/16 1/16 1/32 ...
0 1 3/2 1 0 -3/4 -7/8 -1/2 0 5/16 ...
-1 -1 3/2 4 15/4 3/4 -21/8 -4 -45/16 ...
0 -5 -15/2 1 15 81/4 77/8 -19/2 ...
5 5 -51/2 -56 -105/4 255/4 1071/8 ...
0 61 183/2 -119 -450 -1683/4 ...
-61 -61 1263/2 1324 -585/4 ...
0 -1385 -4155/2 3881 ...
1385 1385 -47751/2
0 50521 ...
-50521 ...
...

The following is the matrix generated by Theorem 3 for the tangent numbers T_n:

1 1 1/2 0 -1/4 -1/4 -1/8 0 1/16 1/16 1/32 0 ...
-1 0 1 1 1/4 -1/2 -3/4 -1/2 -1/16 1/4 5/16 ...
0 -2 -1 2 7/2 2 -1 -3 -11/4 -7/8 ...
2 0 -8 -8 4 16 15 1 -113/8 ...
0 16 8 -40 -64 -10 83 120 ...
-16 0 136 136 -206 -548 -342 ...

-7936 0 176896 ...
0 -353792 ...
353792 ...
...

Using Eq.(1) and Eq.(3) in Theorem 2 and 3, we can give closed formulae for $E_n(0)$, $E_n(1)$, E_n, and T_n.

Corollary.

$$E_n(0) = \sum_{m=0}^{n} \frac{(-1)^m m! \left\{ {n \atop m} \right\}}{2^m}, \qquad E_n = \sum_{m=0}^{n} (-1)^m m! \left\{ {n+1 \atop m+1} \right\} a_{0,m},$$

$$E_n(1) = \sum_{m=0}^{n} \frac{(-1)^m m! \left\{ {n+1 \atop m+1} \right\}}{2^m}, \qquad T_n = \sum_{m=0}^{n} (-1)^m m! \left\{ {n \atop m} \right\} a_{0,m},$$

where $\{a_{0,m}\}_{m=0}^{\infty}$ *is the initial sequence in Theorem 3.*

Remark. A referee mentions that the B-algorithm may well yield other notable sequences. For instance, the Bell numbers can be obtained from the initial sequence $(-1)^n/n!$, since their exponential generating function is

$$B(x) = A(1 - e^x) = \sum_{m=0}^{\infty} \frac{(e^x - 1)^m}{m!} = e^{e^x - 1}.$$

Acknowledgements. I would like to thank the referee for some useful comments and suggestions.

A sequence related to a conjecture of Schinzel

Matthew M. Conroy
5212 Ravenna Avenue NE, Apt. #8
Seattle, WA 98105, USA
Email: doctormatt@earthlink.net

Abstract: It would follow from a conjecture of Schinzel that all positive integers are representable as (p+1)/(q+1) with q and p prime. This conjecture is verified to 10^9, and various results of the calculation are given.

A consequence of an unproved conjecture of Schinzel[1] is that every positive integer n can be represented as n=(p+1)/(q+1), with p and q prime. For n a positive integer, define the function q(n) to be the smallest prime q such that n(q+1)-1 is prime. In other words, let q(n) be the smallest prime q so that n has a representation n=(p+1)/(q+1) with p prime. The sequence q(n) begins 2,2,3,2,3,2,5,2,5,2,3,3,7 (sequence A060324 in [2]; the values of p form sequence A062251). I have verified that q(n) exists for all $n < 10^9$.

Generally, q(n) is quite a small prime. For example, letting v(x,q) = #{ n <= x : q=q(n) }, we have, for q <= 31:

q	$v(10^3, q)$	$v(10^4, q)$	$v(10^5, q)$	$v(10^6, q)$	$v(10^7,q)$	$v(10^8,q)$
2	222	1634	13026	108476	929119	8126474
3	223	1796	14962	128051	1117099	9903208
5	236	2085	18339	162796	1456211	13149129
7	93	971	9276	86491	800838	7418842
11	102	1095	11324	109516	1041573	9838207
13	35	524	6045	62243	617983	6044694

17	31	522	6204	66859	685210	6830034
19	13	261	3349	38962	420793	4369435
23	20	316	4097	46593	501096	5181342
29	12	261	3839	46723	520540	5518907
31	2	67	1039	14343	176355	1986081

Notice that, for a fixed x, v(x,q) to some extent reflects the number of prime factors of q+1. This makes sense, since the more prime factors q+1 has, the more likely it is that $(q+1)^n - 1$ is prime.

The following table gives the maximal values for q(n) (that is, values of n for which q(n') < q(n) for every n' < n).

n	q(n)	(log q(n))/(log n)	(log q(n))/(log log n)

This table is complete for n < 10^9 (the first two colums are sequences A060424 and A062252; the corresponding values of p give A062256). The fact that the maximal values of q(n) are so small (apparently less than log n to a fixed power) is supportive of the conjecture that it is always defined. Indeed, on average q(n) was found to be quite a bit smaller. Let Q(x) be the sum of q(n) for all n <= x. We have the following table:

x	Q(x)	Q(x)/(x log x log log x)
10^2	427	0.607145
10^3	6680	0.500366
10^4	101494	0.496304
10^5	1354578	0.481517
10^6	17189068	0.473833
10^7	210240001	0.469208
10^8	2501065886	0.466024
10^9	29118770352	0.463545

A heuristic argument can be given to explain the behavior seen in this table. We can think of q(n) as representing the k-th prime, where k is the number of primes p_i (p_1=2, p_2=3, etc.) that need to be run through before $n(p_i+1)-1$ is prime. Assuming the p_i are small compared to n, the probability of $n(p_i+1)-$

1 being prime is about 1/log n. Hence we expect to need to run through about log n primes. Since the log of the n-th prime is roughly log n log log n, we can expect q(n) to be about log n log log n on average.

Finally, let s(x) be the number of n <= x for which q(n) = q(n-1). We have the following table:

x	s(x)	(log(s(x)/x))/(log log x)	(s(x) log x)/ x
10^5	6881	-1.095330	0.792204
10^6	60547	-1.067996	0.836488
10^7	539273	-1.050424	0.869205
10^8	4874595	-1.036952	0.897934

The two right-hand columns both indicate the same thing: that s(x) appears to be approximately x/log x.

Abstract

We consider two families of plane partitions: totally symmetric self-complementary plane partitions (TSSCPPs) and cyclically symmetric transpose complement plane partitions (CSTCPPs). If $T(n)$ and $C(n)$ are the numbers of such plane partitions in a $2n \times 2n \times 2n$ box, then

$$ord_2(T(n)) = ord_2(C(n))$$

for all $n \geq 1$. We also discuss various consequences, along with other results on $ord_2(T(n))$.

Keywords: alternating sign matrices, totally symmetric self-complementary plane partitions, TSSCPP, cyclically symmetric transpose complement plane partitions, CSTCPP, Jacobsthal numbers

1 Introduction

In his book "Proofs and Confirmations," David Bressoud [2] discusses the rich history of the Alternating Sign Matrix conjecture and its proof. One of the themes of the book is the connection between alternating sign matrices and various families of plane partitions. (Reference [3] gives a synopsis of this work.)

Pages 197–199 of [2] list ten families of plane partitions which have been extensively studied. The last family in this list is the set of totally symmetric self–complementary plane partitions (TSSCPPs) which fit in a $2n \times 2n \times 2n$ box. In 1994, Andrews [1] proved that the number of such partitions is given by

$$T(n) = \prod_{j=0}^{n-1} \frac{(3j+1)!}{(n+j)!}. \tag{1}$$

[1]Current address: Department of Mathematics, Eberly College of Science, The Pennsylvania State University, University Park, PA 16802

(This formula also gives the number of $n \times n$ alternating sign matrices. See [9]. The values $T(n)$ can be found as sequence A005130 in [8].)

Another family mentioned by Bressoud is the set of cyclically symmetric transpose complement plane partitions (CSTCPPs). We will let $C(n)$ denote the number of such partitions that fit in a $2n \times 2n \times 2n$ box. (The values $C(n)$ make up sequence A051255 in [8].) In 1983, Mills, Robbins, and Rumsey [7] proved that

$$\begin{aligned} C(n) &= \prod_{j=0}^{n-1} \frac{(3j+1)(6i)!(2i)!}{(4i+1)!(4i)!} \\ &= \prod_{j=0}^{n-1} \frac{(3j+1)!(6i)!(2i)!}{(3j)!(4i+1)!(4i)!}. \end{aligned} \tag{2}$$

The goal of this note is to consider arithmetic properties of, and relationships between, the two functions $T(n)$ and $C(n)$. In particular, we will prove that, for all $n \geq 1$,

$$ord_2(T(n)) = ord_2(C(n))$$

where $ord_2(m)$ is the highest power of 2 dividing m. This is the gist of Section 2 below. Using this fact and additional tools developed in Section 3, we will prove the following congruences:

1. For all $n \geq 0$,
$$T(n) \equiv C(n) \pmod 4.$$
2. For all $n \geq 0$, n not a Jacobsthal number,
$$T(n) \equiv C(n) \pmod{16}.$$

(The Jacobsthal numbers $\{J_n\}_{n=0}^{\infty}$ are the numbers satisfying $J_0 = J_1 = 1$ and $J_{n+2} = J_{n+1} + 2J_n$ for $n \geq 0$. The values J_n make up sequence A001045 in [8].)

Indeed, if we ignore those values of n which are Jacobsthal numbers, we will prove that, for fixed $k \geq 1$,

$$T(n) \equiv C(n) \pmod{2^k}$$

for all but a finite set of values of n. Moreover, the values of n for which this congruence does not hold must satisfy $n \leq J_{2k+1}$. This extends earlier work of the authors [4].

The above results imply some interesting arithmetic properties of $C'(n)$, the number of CSTCPPs in a $2n \times 2n \times 2n$ box which are not TSSCPPs. In particular, we have

$$C'(n) \equiv 0 \pmod 4$$

for all $n \geq 0$. Moreover, we have, for fixed $k \geq 1$,

$$C'(n) \equiv 0 \pmod{2^k}$$

for all but finitely many non-Jacobsthal numbers. There does not appear to be any obvious reason why this property should hold, nor why $C'(n)$ behaves differently when n is a Jacobsthal number.

2 The 2-adic Relationship Between $C(n)$ and $T(n)$

Throughout this note, we make use of the following lemma:

Lemma 2.1. *For any prime p and positive integer N,*

$$ord_p(N!) = \sum_{k\geq 1} \left\lfloor \frac{N}{p^k} \right\rfloor.$$

Proof. For a proof, see [6, Theorem 2.29]. □

The goal of this section is to prove the following theorem:

Theorem 2.2. *For all $n \geq 1$,*

$$ord_2(C(n)) = ord_2(T(n)).$$

Proof. The proof simply involves a manipulation of various sums using Lemma 2.1. Given (2), we have

$$\begin{aligned}
ord_2(C(n)) &= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{3j+1}{2^k}\right\rfloor + \left\lfloor \frac{6j}{2^k}\right\rfloor - \left\lfloor \frac{3j}{2^k}\right\rfloor + \left\lfloor \frac{2j}{2^k}\right\rfloor - \left\lfloor \frac{4j}{2^k}\right\rfloor - \left\lfloor \frac{4j+1}{2^k}\right\rfloor \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{3j+1}{2^k}\right\rfloor + \left(\left\lfloor \frac{3j}{2^{k-1}}\right\rfloor - \left\lfloor \frac{3j}{2^k}\right\rfloor\right) + \left\lfloor \frac{2j}{2^k}\right\rfloor - 2\left\lfloor \frac{4j}{2^k}\right\rfloor \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\{\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \left(2\left\lfloor \frac{2j}{2^{k-1}}\right\rfloor - \left\lfloor \frac{j}{2^{k-1}}\right\rfloor\right)\right\} + \sum_{j=0}^{n-1} 3j \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\{\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \left(2\left\lfloor \frac{2j}{2^k}\right\rfloor - \left\lfloor \frac{j}{2^k}\right\rfloor + 2(2j) - j\right)\right\} + \sum_{j=0}^{n-1} 3j \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\{\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \left(2\left\lfloor \frac{2j}{2^k}\right\rfloor - \left\lfloor \frac{j}{2^k}\right\rfloor\right)\right\} + \sum_{j=0}^{n-1}(3j - 4j + j) \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\{\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \left(\left\lfloor \frac{2j}{2^k}\right\rfloor + \left\lfloor \frac{2j+1}{2^k}\right\rfloor - \left\lfloor \frac{j}{2^k}\right\rfloor\right)\right\} \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \sum_{j=0}^{2n-1}\sum_{k\geq 1}\left\lfloor \frac{j}{2^k}\right\rfloor + \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{j}{2^k}\right\rfloor \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \sum_{j=n}^{2n-1}\sum_{k\geq 1}\left\lfloor \frac{j}{2^k}\right\rfloor \\
&= \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{3j+1}{2^k}\right\rfloor - \sum_{j=0}^{n-1}\sum_{k\geq 1}\left\lfloor \frac{n+j}{2^k}\right\rfloor \\
&= ord_2(T(n))
\end{aligned}$$

again using Lemma 2.1 and (1).

□

3 A Finiteness Result

In this section, we show that there is an upper bound on the values of n for which $ord_2(T(n)) = k$ for any positive integer k. To do this, we use insight obtained from our work in [4]. In that paper, we studied the

functions

$$N_k^{\#}(n) = \sum_{j=0}^{n-1} \left\lfloor \frac{3j+1}{2^k} \right\rfloor \text{ and } D_k^{\#}(n) = \sum_{j=0}^{n-1} \left\lfloor \frac{n+j}{2^k} \right\rfloor$$

which implicitly appear in

the second-to-last line of the string of equalities in the proof of Theorem 2.2.

Definition 3.1. *We define the function* $c_k(n) := N_k^{\#}(n) - D_k^{\#}(n)$ *for any positive integer* n, *so that* $ord_2(T(n)) = \sum_{k\geq 1} c_k(n)$.

Theorem 3.2. *Suppose* $0 \leq \rho_k < 2^k$. *Then*

$$c_k(\rho_k) = \begin{cases} 0 & \text{if } 0 \leq \rho_k \leq J_{k-1} \\ \rho_k - J_{k-1} & \text{if } J_{k-1} < \rho_k \leq 2^{k-1} \\ J_k - \rho_k & \text{if } 2^{k-1} \leq \rho_k < J_k \\ 0 & \text{if } J_k \leq \rho_k < 2^k. \end{cases}$$

Moreover,

$$c_k(n + 2^k) = c_k(n) \text{ for all } n, k \text{ in } \mathbb{N}.$$

Furthermore, if $n = 2^k q_k + \rho_k$, *then*

$$c_k(n) = c_k(2^k(q_k + 1) - \rho_k).$$

Proof. This follows from Lemmas 5.1 through 5.4 of [4] for n which are not Jacobsthal numbers (though in the case of Lemmas 5.2 and 5.3 of [4] one has to look inside the proof to get this stronger result), and Theorem 4.1 of [4] for n which are Jacobsthal numbers. □

Since the submission of this article, the authors have found a simpler proof of Theorem 3.2, which will appear in [5]. It is clear from Theorem 3.2 that the values of the function c_k increase in increments of 1 beginning at J_{k-1}, reach a peak at 2^{k-1}, and then decrease in increments of 1 between 2^{k-1} and J_k. Propositions 3.3 and 3.4 show us that when the parities of i and j are the same, the ascents for c_i and c_j "line up" in such a way that if say $j > i$, c_i is beginning one of its ascents at the same point that c_j is beginning an ascent, so that there is an interval where the two agree. Of course c_i will reach its peak first, so beyond that point, the two will fail to agree for some time. However, given the periodic nature of these functions, they will realign at some later point. See the table in the Appendix for a demonstration of this phenomenon.

We use this insight to achieve a lower bound for $ord_2(T(n))$ when n is between two Jacobsthal numbers.

Proposition 3.3. *For* $0 \leq i \leq \left\lceil \frac{k}{2} - 1 \right\rceil$,

$$J_k = J_{k-2i} + J_{2i-1} \cdot 2^{k-2i+1}.$$

Proof. Recall from [4] that, for all $m \geq 0$, $J_m = \frac{2^{m+1} + (-1)^m}{3}$. Then

$$\begin{aligned} J_{k-2i} + J_{2i-1} \cdot 2^{k-2i+1} &= \frac{2^{k-2i+1} + (-1)^{k-2i} + 2^{2i} \cdot 2^{k-2i+1} + (-1)^{2i-1} 2^{k-2i+1}}{3} \\ &= \frac{2^{k+1} + (-1)^k}{3} \text{ upon simplification} \\ &= J_k. \end{aligned}$$

□

Proposition 3.3 allows us to show that, for a given n, the functions c_k are equal to each other for several values of k.

Proposition 3.4. *Suppose* $J_k \leq n \leq 2^k$, *say* $n = J_k + r$ *where* $r \geq 0$. *If* $0 \leq i \leq \left\lceil \frac{k}{2} - 1 \right\rceil$ *and* $0 \leq r \leq J_{k-1-2i}$,

then

$$c_{k+1-2i}(n) = r.$$

Proof. This follows from Theorem 3.2 and Proposition 3.3. □

A symmetric result is true when $2^k \leq n \leq J_{k+1}$.

Corollary 3.5. *Suppose* $2^k \leq n \leq J_{k+1}$, *say* $n = J_{k+1} - r$ *where* $r \geq 0$.

If $0 \leq i \leq \left\lceil \frac{k}{2} - 1 \right\rceil$ *and* $0 \leq r \leq J_{k-1-2i}$, *then*

$$c_{k+1-2i}(n) = r.$$

Proof. This result follows directly from the fact stated in Theorem 3.2 which says that, if $n = 2^k q_k + \rho_k$, then

$$c_k(n) = c_k(2^k(q_k + 1) - \rho_k).$$

In our case, we replace k by $k+1$ and note that $q_{k+1} = 0$, so we have

$$\begin{aligned} c_{k+1}(n) &= c_{k+1}(J_{k+1} - r) \\ &= c_{k+1}(2^{k+1} - (J_{k+1} - r)) \\ &= c_{k+1}(J_k + r) \text{ using [4, Lemma 3.2]} \\ &= r \text{ by Proposition 3.4.} \end{aligned}$$

□

Theorem 3.6. *Let* $i, k \in \mathbb{N}$ *such that* $0 \leq i \leq \left\lceil \frac{k}{2} - 1 \right\rceil$ *and* $k - i$ *odd. If* $(J_i + 1) \leq r \leq 2^k - (J_i + 1)$, *then*

$$ord_2(T(J_k + r)) \geq (J_i + 1)\left(\frac{k - i - 1}{2}\right).$$

Proof. If $r \leq J_{k-2i-1}$, where $0 \leq i \leq \left\lceil \frac{k}{2} - 1 \right\rceil$, then by Proposition 3.4 or Corollary 3.5,

$$c_{k+1-2i}(J_k + r) = r.$$

Now, suppose i is such that $k-i$ is odd and let $2j+1 = k-i$. If $J_i+1 \leq r \leq J_{k-1}$, then $r \not\leq J_i = J_{k-(k-i)} = J_{k-1-2j}$, but $r \leq J_{i+2} = J_{k-(k-i-2)} = J_{k-1-2(j-1)}$. Hence

$$c_{k+1}(J_k + r) = c_{k-1}(J_k + r) = \cdots = c_{k+1-2(j-1)}(J_k + r) = r.$$

Thus, $ord_2(T(J_k + r))$ has $j = \frac{k-i-1}{2}$ summands of value r, so that

$$ord_2(T(J_k + r)) \geq r\left(\frac{k - i - 1}{2}\right) \geq (J_i + 1)\left(\frac{k - i - 1}{2}\right).$$

□

Corollary 3.7. *If $J_{m-1} < n < J_m$, then*

$$ord_2(T(n)) \geq \left\lfloor \frac{m}{2} \right\rfloor.$$

Proof. We break the proof into two cases. First, assume that $m = 2k$, so $n = J_{2k-1}+r$ where $0 < r < 2J_{2k-2}$. Using Theorem 3.6 with $i = 0$ yields

$$\begin{aligned} ord_2(T(n)) &\geq (J_0 + 1)(k-1) \quad \text{if } 2 \leq r \leq 2J_{2k-2} - 2 \\ &> k. \end{aligned}$$

If $r = 1$ or $r = 2J_{2k-2} - 1$ then

$$c_{2k}(n) = c_{2k-2}(n) = \cdots = c_2(n) = 1$$

noting that $2 = 2k - 2(k-1)$, so

$$ord_2(T(n)) \geq k.$$

Since $k = \left\lfloor \frac{m}{2} \right\rfloor$, we have our result.

Next, assume that $m = 2k + 1$, so $n = J_{2k} + r$ where $0 < r < 2J_{2k-1}$. Using Theorem 3.6 with $i = 1$ yields

$$\begin{aligned} ord_2(T(n)) &\geq (J_1 + 1)(k-1) \quad \text{if } 2 \leq r \leq 2J_{2k-1} - 2 \\ &> k. \end{aligned}$$

If $r = 1$ or $r = 2J_{2k-1} - 1$ then

$$c_{2k+1}(n) = c_{2k-1}(n) = \cdots = c_3(n) = 1$$

noting that $3 = 2k + 1 - 2(k-1)$, so

$$ord_2(T(n)) \geq k.$$

Since $k = \left\lfloor \frac{m}{2} \right\rfloor$, we have our result. □

Corollary 3.8. *If $ord_2(T(n)) = k$ with $k \geq 1$, then $n < J_{2k+1}$.*

Proof. Suppose $ord_2(T(n)) = k$. From [4, Theorem 4.1], n is not a Jacobsthal number since $ord_2(T(J_i)) = 0$ for all i. Moreover, by Corollary 3.7, if $J_{2j-1} < n < J_{2j+1}$, then $ord_2(T(n)) \geq j$. So if $j > k$, n is not between J_{2j-1} and J_{2j+1}. The largest number remaining is $J_{2k+1} - 1$ and, in fact, $ord_2(T(J_{2k+1} - 1)) = k$. □

4 Implications

It is clear from Theorem 2.2 that

$$T(n) \equiv C(n) \pmod 2.$$

However, much more can be said.

Theorem 4.1. *For all $n \geq 1$,*

$$T(n) \equiv C(n) \pmod 4.$$

Proof. Given Theorem 2.2, it is clear that Theorem 4.1 is automatically true for those values of n for which $ord_2(T(n)) \geq 1$. Hence, we only need to focus on those n for which $ord_2(T(n)) = 0$.

As noted in [4], $ord_2(T(n)) = 0$ if and only if n is a Jacobsthal number. Via straightforward calculations based on (1) and (2), it can be proved that, for all $m \geq 1$,

$$T(J_m) \equiv C(J_m) \equiv (-1)^{m-1} \pmod 4.$$

□

Theorem 4.2. *For all $n \geq 1$, n not a Jacobsthal number,*

$$T(n) \equiv C(n) \pmod{16}.$$

Proof. We need only check those values of n for which $1 \leq ord_2(T(n)) \leq 2$, so, from Corollary 3.8, only $1 \leq n \leq J_5 - 1$ or $1 \leq n \leq 20$. This is straightforward using Maple and (1) and (2). □

One last congruential implication is noted here.

Theorem 4.3. *For all positive integers k and all but finitely many $n \geq 1$, n not a Jacobsthal number,*

$$T(n) \equiv C(n) \pmod{2^k}.$$

Proof. This is quickly proved since all that must be checked are those values of n for which $1 \leq ord_2(T(n)) \leq k-2$. Corollary 3.8 implies that the only nonJacobsthal positive integers n for which $ord_2(T(n)) \leq k-2$ satisfy $1 \leq n \leq J_{2k+1} - 1$. □

Finally, we note that results analogous to Corollary 3.8 and Theorem 4.3 do not appear to hold for primes $p > 2$. We have confirmed this computationally in regards to Theorem 4.3, and have proved that the finiteness result in Corollary 3.8 can only hold for $p = 2$. In fact, we [5] have proved the following:

Theorem 4.4. *If p is a prime greater than 3, then for each nonnegative integer k there exist infinitely many positive integers n for which $ord_p(A(n)) = k$.*

A result similar to Theorem 4.4 can be proved for $p = 3$, although it is a bit weaker. See [5].

Appendix

The table below includes the values of the functions $c_2(n)$, $c_4(n)$, $c_6(n)$ and $c_8(n)$ for n between 85 and 171, which are the Jacobsthal numbers J_8 and J_9. We provide this table to show the periodic nature of the functions $c_k(n)$, and to motivate Proposition 3.3. It should be noted that, if we were to build a similar table for values of n between J_{2m-1} and J_{2m}, then we would focus attention on functions $c_k(n)$ where k is odd rather than even.

Abstract

Two natural properties of integer sequences are introduced and studied. The first, exact realizability, is the property that the sequence coincides with the number of periodic points under some map. This is shown to impose a strong inner structure on the sequence. The second, realizability in rate, is the property that the sequence asympototically approximates the number of periodic points under some map. In both cases we discuss when a sequence can have that property. For exact realizability, this amounts to examining the range and domain among integer sequences of the paired transformations

$$Per_n = \sum_{d\,n} d\ Orb_d; \qquad Orb_d = \frac{1}{n}\sum_{d\,n} \mu(n/d) Per_d \qquad \textbf{ORBIT}$$

that move between an arbitrary sequence of non-negative integers Orb counting the orbits of a map and the sequence Per of periodic points

[1]The first author gratefully acknowledges the support of E.P.S.R.C. grant 96001638

for that map. Several examples from the Encyclopedia of Integer Sequences arise in this work, and a table of sequences from the Encyclopedia known or conjectured to be exactly realizable is given.

1. Introduction

Let $T : X \to X$ be a map. Three measures of growth in complexity for T are given by the *number of points with period* n,

$$f_n(T) = \#\{x \in X \mid T^n x = x\},$$

the *number of points with least period* n,

$$f_n(T) = \#\{x \in X \mid T^n(x) = x \text{ and } \#\{T^k x\}_{k\ \mathbb{Z}} = n\},$$

and the *number of orbits of length* n,

$$f_n^o(T) = f_n(T)/n.$$

In this note we assume that $f_n(T)$ is finite for $n \geq 1$ and give some results on what arithmetic properties the sequence $(f_n(T))$ may have, and show when the growth in $(f_n(T))$ is related to the growth in $(f_n(T))$. It will be convenient to adopt the following notation: a sequence $a_1, a_2, a_3, \ldots$ is denoted (a_n) or simply a.

Definition 1.1. Let $\phi = (\phi_n)$ be a sequence of non-negative integers. Then

(1) $\phi \in \mathcal{ER}$ (*exactly realizable*) if there is a set X and a map $T : X \to X$ for which $f_n(T) = \phi_n$ for all $n \geq 1$;
(2) $\phi \in \mathcal{RR}$ (*realizable in rate*) if there is a set X and a map $T : X \to X$ for which $f_n(T)/\phi_n \to 1$ as $n \to \infty$.

None of the results below are changed if the realizing maps are required to be homeomorphisms of a compact X, but this is not pursued here.

2. Exact realization

The set of points with period n under T is the disjoint union of the set of points with least period d under T for d dividing n, so

$$f_n(T) = \sum_{d\ n} f_d(T). \tag{1}$$

Equation (1) may be inverted via the Möbius inversion formula to give

$$f_n(T) = \sum_{d\ n} \mu(n/d) f_d(T), \tag{2}$$

where $\mu(\cdot)$ is the Möbius function. On the other hand, the set of points with least period n comprises exactly f_n^o orbits each of length n, so

$$0 \leq f_n(T) = \sum_{d\,n} \mu(n/d) f_d(T) \equiv 0 \bmod n. \tag{3}$$

It is clear (since one may take $X = \mathbb{N}$ and make T to be a permutation with the appropriate number of cycles of each length) that these are the only conditions for membership in $\mathcal{ER}$.

Lemma 2.1. *Let ϕ be a sequence of non-negative integers. Then $\phi \in \mathcal{ER}$ if and only if $\sum_{d\,n} \mu(n/d)\phi_d$ is non-negative and divisible by n for all $n \geq 1$.*

Everything that follows is a consequence of this lemma. Before considering properties of $\mathcal{ER}$ as a whole, some examples are considered. The sequences that arise here are therefore close in spirit to the 'eigensequences' for the transformation **MÖBIUS** discussed in [1] with the additional requirement that the sequence f be divisible by n and non-negative.

Example 2.2. (1) The Fibonacci sequence A000045 is not in $\mathcal{ER}$. Using (3) we see that $f_3 - f_1$ must always be divisible by 3, but the Fibonacci sequence begins $1, 1, 2, 3, \ldots$. By contrast the golden mean shift (see [10]) shows that the closely related Lucas sequence A000204 is in $\mathcal{ER}$. This will be dealt with in greater generality in Section 2.2 below.

(2) For any map T, equation (3), when n is a prime p, states that

$$f_p(T) \equiv f_1(T) \bmod p.$$

If $A \in GL_k(\mathbb{Z})$ is an invertible integer matrix with no unit root eigenvalues, then the periodic points in the corresponding automorphism of the k-torus show that

$$\det(A^p - I) \equiv \det(A - I) \bmod p$$

for all primes p.

(3) Similarly, if $B \in M_k(\mathbb{N})$ is a matrix of non-negative integers, the associated subshift of finite type (see [10]) shows that

$$\operatorname{trace}(B^p) \equiv \operatorname{trace}(B) \bmod p$$

for all primes p. When $k = 1$ this is Fermat's little theorem. When $B = [2]$, so $f_n = 2^n$, f_n^o is the sequence A001037 (shifted by one) counting irreducible polynomials of degree n over $\mathbb{F}_2$.

(4) The subshifts of finite type give a family of elements of $\mathcal{ER}$ of exponential type. Another family comes from Pascal's triangle: if $k > 1$, $1 \leq j < k$ and $a_n = \binom{kn}{jn}$, then $a \in \mathcal{ER}$. For $k = 2$ and $j = 1$, if $f_n = f_n(T)$ for the realizing map T, then f_n is the sequence A007727 counting $2n$-bead black and white strings with n black beads and fundamental period $2n$.

(5) Connected S-integer dynamical systems (see [3], [13] for these and the next example): a subset $S \subset \{2, 3, 5, 7, 11, \dots\}$ and a rational $\xi \neq 0$ are given with the property that $|\xi|_p > 1 \implies p \in S$. The resulting system constructs a map $T : X \to X$ for which

$$f_n(T) = \prod_p |\xi^n - 1|_p.$$

With $\xi = 2, S = \{2, 3, 5, 7\}$ this gives the sequence

$$1, 1, 1, 1, 31, 1, 127, 17, 73, 341, 2047, 13, 8191, 5461, 4681, \dots$$

in $\mathcal{ER}$.

(6) Zero-dimensional S-integer dynamical systems: a prime p is fixed, a subset S of the set of all irreducible polynomials in $\mathbb{F}_p[t]$ and a rational function $\xi \in \mathbb{F}_p(t)$ are given, with the property that $|\xi|_f > 1 \implies f \in S$. The resulting system constructs a map $T : X \to X$ for which

$$f_n(T) = |\xi^n - 1|_{t^{-1}} \times \prod_{f \ S} |\xi^n - 1|_f$$

where $|\cdot|_{t^{-1}}$ is used to denote the valuation 'at infinity' induced by $|t|_{t^{-1}} = p$. Taking $p = 2$, $S = \{t - 1\}$ and $\xi = t$ gives the formula

$$f_n(T) = 2^{n \ 2^{\mathrm{ord}_2(n)}}$$

and the sequence A059991 in $\mathcal{ER}$.

2.1. **Algebra in $\mathcal{ER}$.** The set $\mathcal{ER}$ – or the ring $K_0(\mathcal{ER})$ – has a very rich structure. Say that a sequence $a \in \mathcal{ER}$ *factorizes* if there exists sequences $b, c \in \mathcal{ER}$ with $a_n = b_n c_n$ for all $n \geq 1$, and is *prime* if such a factorization requires one of b or c to be the constant sequence (1).

Lemma 2.3. *$\mathcal{ER}$ contains the constant sequences and is closed under addition and multiplication. Elements of $\mathcal{ER}$ may have infinitely many non-trivial factors. There are non-trivial primes in $\mathcal{ER}$.*

Proof. The constant sequence (1) is in $\mathcal{ER}$ since it is realized by taking X to be a singleton. The condition in Lemma 2.1 is closed under addition. On the other hand, if ϕ and ψ are exactly realized by systems (X,T) and (Y,S), then $(X\times Y, T\times S)$ exactly realizes $(\phi_n\cdot\psi_n)$. For each $k\geq 1$ define a sequence $r^{(k)}$ by $r_n^{(k)}=0$ for $1<n\leq k$ and $r_n^{(k)}=1$ for $n>k$ or $n=1$. Then $a^{(k)}\in\mathcal{ER}$, where $a_n^{(k)}=\sum_{d\,n} dr_d^{(k)}$. Since for each n the sequence $a_n^{(1)}, a_n^{(2)}, a_n^{(3)},\dots$ has only finitely many terms not equal to 1, the product $\prod_{k\ 1} a^{(k)}=(1,3,16,245,1296,41160,\dots)$ is an element of $\mathcal{ER}$ with infinitely many non-trivial factors. Finally, the sequence $(1,3,1,3,\dots)$ is a non-trivial prime in $\mathcal{ER}$. □

In [9, Sect. 6] a periodic point counting argument is used to show that the full p-shift, for p a prime, is not topologically conjugate to the direct product of two dynamical systems. In that argument, special properties of subshifts of finite type are needed (specifically, the fact that $f_{p^k}(T)=1$ for all $k\geq 1$ implies that $f_n(T)=1$ for all $n\geq 1$ for such systems). This result does not follow from the arithmetic of $\mathcal{ER}$ alone: for example, $(3^n)\in\mathcal{ER}$ factorizes into $(1,3,1,3,\dots)\times(3,3,3^3,3^3,\dots)$ in $\mathcal{ER}$ (neither of which can be realized using a subshift of finite type). A similar factorization is possible for (p^n) and any odd prime p (see [11] for the details).

Lemma 2.4. *There are no non-constant polynomials in $\mathcal{ER}$. There are non-trivial multiplicative sequences in $\mathcal{ER}$, but there are no completely multiplicative sequences apart from the constant sequence* (1).

Proof. Assume that

$$P(n)=c_0+c_1n+\cdots+c_kn^k$$

with $c_k\neq 0$, $k\geq 1$, and that $(P(n))\in\mathcal{ER}$. After multiplying the divisibility condition (3) by the least common multiple of the denominators of the (rational) coefficients of P, we produce a polynomial with integer coefficients satisfying (3). It is therefore enough to assume that the coefficients c_i are all integers. Let (f_n) and (f_n) be the periodic points and least periodic points in the corresponding system (X,T), and let p be any prime. By (2),

$$f_{p^2}=f_{p^2}-f_p,$$

so

$$\begin{aligned} f^o_{p^2} = \frac{f_{p^2}}{p^2} &= \frac{f_{p^2} - f_p}{p^2} \\ &= \frac{1}{p^2}\left(c_1p^2 + c_2p^4 + \cdots + c_kp^{2k} - (c_1p + c_2p^2 + \cdots + c_kp^k)\right) \\ &\in -\frac{c_1}{p} + \mathbb{Z}, \end{aligned}$$

and therefore p divides c_1 for all primes p, showing that $c_1 = 0$.

Now let q be another prime, and recall that

$$\mu(1) = 1, \mu(p) = -1, \mu(q) = -1, \mu(p^2) = 0, \mu(p^2q) = 0, \mu(pq) = 1.$$

Since $c_1 = 0$,

$$f_n = c_0 + n^2(c_2 + c_3n + \cdots + c_kn^{k\ \ 2}), \tag{4}$$

and by (3)

$$p^2q \big| f_{p^2q} - f_{pq} - f_{p^2} + f_p = f_{p^2q},$$

so

$$\frac{f_{p^2} - f_p}{p^2q} \in \mathbb{Z}$$

by (4). It follows that

$$c_0(1-1) + c_2(p^4 - p^2) + c_3(p^6 - p^3) + \cdots + c_k(p^{2k} - p^k) \in q\mathbb{Z}$$

for all primes q and p (since $f_{p^2} - f_p$ is certainly divisible by p^2). So

$$c_0(1-1) + c_2(p^4 - p^2) + c_3(p^6 - p^3) + \cdots + c_k(p^{2k} - p^k) = 0;$$

taking the limit as $p \to \infty$ of $\frac{1}{p^{2k}}(f_{p^2} - f_p)$ shows that $c_k = 0$. This contradiction proves the first statement.

There are many multiplicative sequences in $\mathcal{ER}$: if f is any multiplicative sequence, then so is the corresponding sequence f (see [7, Theorem 265]). A multiplicative sequence ϕ is *completely multiplicative* if $\phi_{nm} = \phi_n\phi_m$ for all $n, m \geq 1$. Assume that $\phi \in \mathcal{ER}$ is completely multiplicative, with f the realising sequence. For p a prime and any $r \geq 1$,

$$f_{p^r} = f_{p^r} - f_{p^{r-1}} = f_p^r - f_p^{r\ \ 1}$$

by (2). It follows that

$$p^r \big| f_p^{r\ \ 1}(f_p - 1).$$

With $r = 1$ this implies that $f_p = 1 + pk_p$ for all p, $k_p \in \mathbb{N}_0$. Now

$$p^r \big| (1 + pk_p)^{r\ \ 1} pk_p$$

for all p and $r \geq 1$. It follows that $k_p \equiv 0 \bmod p^r$ for all $r \geq 1$, so $k_p = 0$ for all p. It follows that $f_p = 1$ for all primes p, so $f_n = 1$ for all $n \geq 1$. □

Examples show that the additive convolution $(\sum_{i+j=n+1,1 \;\; i,j \;\; n} \phi_i \psi_j)$ of sequences $\phi, \psi \in \mathcal{ER}$ is not in general in $\mathcal{ER}$. Similarly, the multiplicative convolution $(\sum_{d\, n} \phi_d \psi_{n/d})$ is not in general in $\mathcal{ER}$. There is also no closure under quotients: $(2^n) \in \mathcal{ER}$ is term-by-term divisible by the constant sequence $(2) \in \mathcal{ER}$, but $(2^{n \;\; 1}) \notin \mathcal{ER}$.

2.2. **Binary recurrence sequences.** In this section we expand on the observation made in Example 2.2.1 by showing that $\mathcal{ER}$ only contains special binary recurrences.

Theorem 2.5. *If $\Delta = a^2 + 4b$ is not a square, and $(a, a^2 + 2b) = 1$, then a sequence u with $u_1, u_2 \geq 1$ satisfying the recurrence*

$$u_{n+2} = au_{n+1} + bu_n \text{ for } n \geq 1 \tag{5}$$

is in $\mathcal{ER}$ if and only if $\frac{u_2}{u_1} = \frac{a^2+2b}{a}$.

As an application, Example 2.2.1 becomes the sharper result that the Lucasian sequence $a, b, a + b, a + 2b, 2a + 3b, \ldots$ lies in $\mathcal{ER}$ if and only if $b = 3a$. Moreover, if $f_1 = 1, f_2 = 1, f_3 = 2, \ldots$ is the Fibonacci sequence, then an easy consequence of Theorem 2.5 is that for any $k \geq 1$ the sequence $f_k, f_{k+1}, f_{k+2}, \ldots$ is not in $\mathcal{ER}$. The more general case with square discriminant, a and $a^2 + 2b$ having a common factor and arbitrary u_1, u_2 is dealt with in [11].

Proof. First assume that $\frac{u_2}{u_1} = \frac{a^2+2b}{a}$. Then, by the assumption, the sequence u is a multiple of the sequence $a, a^2 + 2b, a^3 + 3ab, \ldots$ which is in $\mathcal{ER}$ because the subshift of finite type corresponding to the matrix $\begin{bmatrix} a & b \\ 1 & 0 \end{bmatrix}$ realizes it (and therefore any multiple of it).

Conversely, assume that u is a sequence in $\mathcal{ER}$ satisfying (5). Write x for the sequence

$$x : 2b, 2ab, 2(a^2b + b^2), \ldots$$

and y for the sequence

$$y : 2ab, 2(a^2b + 2b^2), \ldots,$$

both satisfying the recurrence (5). Notice that

$$2bu_n = Ax_n + By_n,$$

for integers A and B. By (3), for any prime p

$$Ax_p + By_p \equiv Ax_1 + By_1 \bmod p. \tag{6}$$

On the other hand, it is well-known that $x_p \equiv 2b(\frac{\Delta}{p}) \bmod p$ (where $(\frac{\Delta}{p})$ is the Legendre symbol), and $y_p \equiv 2ab \bmod p$ (by the previous

paragraph: y is in $\mathcal{ER}$). So (6) implies that

$$2bA\left(\left(\frac{\Delta}{p}\right)-1\right)\equiv 0 \bmod p \tag{7}$$

for all primes p.

We now claim that the Legendre symbol $(\frac{\Delta}{p})$ is -1 for infinitely many values of the prime p. This completes the proof of Theorem 2.5, since (7) forces $A=0$ and hence u is a multiple of $\frac{1}{2b}y$, namely $a, a^2+2b, \ldots$.

To see the claim, choose c such that $(c,\Delta)=1$ and the Jacobi symbol $(\frac{c}{\Delta})=-1$. Then by Dirichlet, there are infinitely many primes p with $p\equiv c \bmod \Delta$ and $p\equiv 1 \bmod 4$. For such primes, $(\frac{p}{\Delta})=(\frac{\Delta}{p})=-1$, which completes the proof. □

The case of square discriminant is much more involved. A full treatment is in [11]; here we simply show by examples that the result as stated no longer holds in general.

Example 2.6. (1) There are infinitely many possible values of the ratio $\frac{u_2}{u_1}$ for binary recurrent sequences in $\mathcal{ER}$ satisfying

$$u_{n+2}=u_{n+1}+2u_n. \tag{8}$$

To see this we construct two different realizing examples and then take linear integral combinations of them. The first is the subshift of finite type T corresponding to the matrix $A=\begin{bmatrix}1 & 2\\ 1 & 0\end{bmatrix}$. This system has (by [10, Proposition 2.2.12]) $f_n(T)=\operatorname{trace}(A^n)$, which is the sequence of Jacobsthal–Lucas numbers A014551:$1,5,7,17,\ldots$ (shifted by one) and has initial ratio 5. On the other hand, the algebraic dynamical system S dual to $x\mapsto -2x$ on the discrete group $\mathbb{Z}[\frac{1}{2}]$ has (see, for example, [3, Lemma 5.2]) $f_n(S)=|(-2)^n-1|$, which begins $3,3,9,15,\ldots$ and has ratio 1. Now we may apply Lemma 2.3 as follows. If $s,t\in\mathbb{N}$ then $(tf_n(T)+sf_n(S))$ in $\mathcal{ER}$ is a sequence satisfying (8). It follows that the set of possible ratios $\frac{u_2}{u_1}$ contains the infinite set $\{\frac{5t+3s}{t+3s} \mid s,t\in\mathbb{N}\}$.

(2) A simpler example is given by the Mersenne recurrence. Since (2^n) and (1) are both in $\mathcal{ER}$, for any $t,s\geq 0$ the sequence $(t2^n+s)$ satisfying the recurrence

$$u_{n+2}=3u_{n+1}-2u_n \tag{9}$$

is in $\mathcal{ER}$. Thus the set of possible ratios $\frac{u_2}{u_1}$ for exactly realizable solutions of (9) contains the infinite set $\left\{\frac{4t+s}{2t+s} \mid s,t\in\mathbb{N}\right\}$.

For higher order recurrences with companion polynomials irreducible over the rationals, it is clear that some analogue of Theorem 2.5 holds. The rational solutions of a kth order reccurence form a rational k-space; the smallest subspace contained in $\mathcal{ER}$ has dimension strictly smaller than k. Is this dimension always 1?

3. Realization in rate

Write $\lfloor x \rfloor$ for the greatest integer less than or equal to x and $\lceil x \rceil$ for the smallest integer greater than or equal to x. In this section we assume that sequences are never zero. Different complications arise from zeros of sequences and these are discussed in detail in [11].

Theorem 3.1. *Let α, β be positive constants.*

(1) *If $\phi_n \to \infty$ with $\frac{\phi_n}{n} \to 0$, then $\phi \notin \mathcal{RR}$.*
(2) *The sequence $(\lfloor n^\alpha \rfloor) \in \mathcal{RR}$ if and only if $\alpha > 1$.*
(3) *The sequence $(\lfloor \beta^n \rfloor) \in \mathcal{RR}$ if and only if $\beta \geq 1$.*

Proof. 1. Assume that $\phi \in \mathcal{RR}$ and let f be the corresponding sequence of periodic points. Then $\frac{f_n}{\phi_n} \to 1$, so $\{\frac{f_n}{\phi_n}\}$ is bounded. It follows that $\{\frac{f_n^*}{\phi_n} = \frac{n}{\phi_n} f_n^o\}$ is bounded, and hence $f_n = n f_n^o = 0$ for all large n. This implies that f_n is bounded, and so $\frac{f_n}{\phi_n} \to 0$, which contradicts the assumption.

2. For $\alpha \in (0,1)$ this follows from part 1. Suppose therefore that $(n) \in \mathcal{RR}$. Then there is a sequence $f \in \mathcal{ER}$ with $f_n/n \to 1$, so for p a prime, $p f_p^o = f_p = f_p - f_1$, and therefore $f_p^o \to 1$ as $p \to \infty$. Since f_p^o is an integer, it follows that $f_p^o = 1$ for all large p. Now let q be another large prime. Then

$$\frac{f_{pq}}{pq} = \frac{f_{pq} + f_p + f_q + f_1}{pq} = \frac{f_{pq}}{pq} + \frac{1}{p} + \frac{1}{q} + \frac{f_1}{pq},$$

so

$$\frac{1}{p} + \frac{1}{q} + \frac{f_1}{pq} - \frac{f_{pq}}{pq} \in \mathbb{Z}.$$

Fix p large and let q tend to infinity to see that

$$\frac{1}{p} \in \mathbb{Z},$$

which is impossible. The same argument shows that f_n/n cannot have any positive limit as $n \to \infty$.

For $\alpha > 1$, let $f_n^o = \lceil n^{\alpha\ \ 1} \prod_{p\, d} (1 - p^{\ \ \alpha}) \rceil$, where the product runs over prime divisors only. Then

$$\sum_{d\, n} d^\alpha \prod_{p\, d} (1 - p^{\ \ \alpha}) = n^\alpha \leq \sum_{d\, n} d f_d^o = f_n \leq n^\alpha + \sum_{d\, n} d,$$

so $0 \le f_n - \phi_n \le o(n^\alpha)$.
3. This is clear: for $\beta < 1$ the sequence is eventually 0; for $\beta > 1$ the construction used in part 2. works. □

There are sequences growing more slowly than n^α in $\mathcal{RR}$: in [11, Chap. 5] it is shown that $(\lfloor Cn^s(\log n)^r \rfloor) \in \mathcal{RR}$ for any $r \ge 1, C > 0, s \ge 1$.

4. Comparing orbits with periodic points

As is well-known, if f grows fast enough, then f grows very much like f (though not conversely in the case of super-exponential growth: cf. Theorem 4.2 below). Throughout this section $f_n = f_n(T)$ and $f_n = f_n(T)$ for some map T.

Remark 4.1. That f_n is close to f_n when f_n is growing exponentially has been commented on by Lind in [8, Sect. 4]. He points out, using (2), that if T is the automorphism of the 2-torus corresponding to the matrix $\begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}$ then $f_{20}(T)$ is only 0.006% smaller than $f_{20}(T)$. The sequence f of periodic points for this map is A004146.

Theorem 4.2. (1) *If* $\frac{1}{n}\log f_n \to C \in [0,\infty]$ *then* $\frac{1}{n}\log f_n \to C$ *also.*
(2) $\frac{1}{n}\log f_n \to C \in (0,\infty)$ *if and only if* $\frac{1}{n}\log f_n \to C$.
(3) *If* $\frac{1}{n}\log f_n \to \infty$ *then* $\left\{\frac{1}{n}\log f_n\right\}$ *may be unbounded with infinitely many limit points.*

Proof. 1. If $\frac{1}{n}\log f_n \to \infty$ then $\frac{1}{n}\log f_n \to \infty$ also, since $f_n \ge f_n$ for all n. If $\frac{1}{n}\log f_n \to C \in [0,\infty)$, then (for n large enough to have $f_n \ne 0$)

$$\begin{aligned} \frac{1}{n}\log f_n \le \frac{1}{n}\log f_n &= \frac{1}{n}\log\left(\sum_{d\,n} f_d\right) \\ &\le \frac{1}{n}\log n + \frac{1}{n}\log \max_{d\,n}\{f_d\}. \end{aligned}$$

For each such n, choose $\tilde{n} \in \{d \mid d|n, f_d \ge f_{d'}\ \forall\ d\,|n\}$ so that $f_{\tilde{n}} = \max_{d\,n}\{f_d\}$ and $\frac{\tilde{n}}{n} \le 1$. Then

$$\begin{aligned} \frac{1}{n}\log f_n &\le \frac{1}{n}\log n + \frac{\tilde{n}}{n}\cdot\frac{1}{\tilde{n}}\log f_{\tilde{n}} \\ &\le \frac{1}{n}\log n + \frac{1}{\tilde{n}}\log f_{\tilde{n}} \to C. \end{aligned}$$

2. It is enough to show that if $\frac{1}{n}\log f_n \to C \in (0,\infty)$ then $\frac{1}{n}\log f_n \to C$ also. For $r \geq 1$,

$$f_r \geq f_r = -\sum_{d\ r,d=r} f_d + f_r \geq f_r - \sum_{d\ r,d=r} f_d.$$

Let R be an upper bound for $\{\frac{1}{n}\log f_n \mid f_n \neq 0\}$ and pick $\epsilon \in (0, 3C)$. Choose N so that

$$r > N \implies e^{r(C\ \ \epsilon)} \leq f_r \leq e^{r(C+\epsilon)}.$$

Then for $r > 2N$ (so that $r\ , N \leq \lfloor \frac{r}{2} \rfloor$),

$$\begin{aligned} f_r \geq f_r &\geq f_r - \sum_{n=1}^{N} f_n - \sum_{n=N+1}^{r/2} f_n \\ &\geq f_r - \left(Ne^{NR} + (r/2-N)e^{r(C+\epsilon)/2}\right) \\ &\geq f_r\left(1 - Ne^{NR\ \ r(C\ \ \epsilon)} - (r/2-N)e^{\ \ r(C\ \ 3\epsilon)/2}\right), \end{aligned}$$

and the bracketed expression converges to 1 as $r \to \infty$. Taking logs and dividing by r gives the result.

3. Write $p_1, p_2, \ldots$ for the sequence of primes. Let $n_r = p_r p_{r+1}$, and define a sequence (f_k) as follows. For k not of the form n_r, define $f_k = k \cdot 2^{k^3}$. For k of the form n_r define f_k according to the following scheme:

$$\begin{aligned} f_{n_1} &= n_1 2^{n_1} \\ f_{n_2} &= n_2 2^{n_2}, f_{n_3} = n_3 2^{2n_3} \\ f_{n_4} &= n_4 2^{n_4}, f_{n_5} = n_5 2^{2n_5}, f_{n_6} = n_6 2^{3n_6} \\ f_{n_7} &= n_7 2^{n_7}, f_{n_8} = n_8 2^{2n_8}, f_{n_9} = n_9 2^{3n_9}, f_{n_{10}} = n_{10} 2^{4n_{10}} \end{aligned}$$

and so on. Then $\frac{1}{n}\log f_n \to \infty$ off the n_r's clearly. Along the sequence (n_r),

$$f_{n_r} = f_{n_r} + f_{p_r} + f_{p_{r+1}} + f_1 \geq f_{p_{r+1}},$$

so

$$\frac{1}{n_r}\log f_{n_r} \geq \frac{1}{p_r p_{r+1}} \log\left(p_{r+1} \cdot 2^{p_{r+1}^3}\right) \to \infty.$$

On the other hand, along a subsequence of n_r's chosen to have $f_{n_r} = n_r 2^{\ell n_r}$ for a fixed $\ell \in \mathbb{N}$ (which will exist by construction), we realize $\ell \log 2$ as a limit point of the sequence $\frac{1}{n}\log f_n$. □

Finally, we turn to comparing these growth rates in a sub-exponential setting. For polynomial growth, the next result shows that f and f are forced to behave very differently.

Theorem 4.3. *Let C and α be positive constants.*

(1) *For $\alpha > 1$, the set $\{\frac{f_n^*}{n^\alpha}\}$ is bounded if and only if $\{\frac{f_n}{n^\alpha}\}$ is bounded.*
(2) *For $\alpha > 1$, $\frac{f_n}{n^\alpha} \to 0$ if and only if $\frac{f_n^*}{n^\alpha} \to 0$.*
(3) *If $\frac{f_n}{n^\alpha} \to C$ for some $\alpha > 1$, then $\{\frac{f_n^*}{n^\alpha}\}$ has infinitely many limit points.*
(4) *If $\frac{f_n^*}{n^\alpha} \to C$ for some $\alpha \geq 1$, then $\{\frac{f_n}{n^\alpha}\}$ has infinitely many limit points.*

Proof. 1. Let R be an upper bound for $\{\frac{f_n^*}{n^\alpha}\}$. Then

$$\frac{f_n}{n^\alpha} \leq \frac{1}{n^\alpha} \sum_{d\ n} R d^\alpha = R \sum_{d\ n} \left(\frac{d}{n}\right)^\alpha \leq R \sum_{d=1} \frac{1}{d^\alpha} < \infty.$$

The converse is obvious.
2. One direction is clear. Assume that $\frac{f_n^*}{n^\alpha} \to 0$. Fix $\epsilon > 0$; choose $M_1 \in \mathbb{N}$ so that

$$n > M_1 \implies \frac{f_n}{n^\alpha} < \frac{\epsilon}{1+\beta}$$

where $\beta = \sum_{k=1} \frac{1}{k^\alpha}$. Choose M_2 so that

$$n > M_2 \implies \sum_{r=1}^{M_1} \frac{f_r}{n^\alpha} < \frac{\epsilon}{1+\beta}.$$

Then for $n \geq \max\{M_1, M_2\}$,

$$\begin{aligned} 0 \leq \frac{f_n}{n^\alpha} = \sum_{d\ n} \frac{f_d}{n^\alpha} &\leq \sum_{r=1}^{M_1} \frac{f_r}{n^\alpha} + \sum_{d\ n, d > M_1} \frac{f_r}{n^\alpha} \\ &= \sum_{r=1}^{M_1} \frac{f_r}{n^\alpha} + \sum_{d\ n, d > M_1} + \frac{d^\alpha}{n^\alpha} \cdot \frac{f_d}{d^\alpha} \\ &\leq \frac{\epsilon}{1+\beta} + \frac{\epsilon}{1+\beta} \sum_{d\ n, d > M_1} \frac{d^\alpha}{n^\alpha} \\ &\leq \frac{\epsilon}{1+\beta} + \beta \frac{\epsilon}{1+\beta} \leq \epsilon. \end{aligned}$$

3. Assume that $\frac{f_n}{n^\alpha} \to C > 0$. Then $\frac{f_p^*}{p^\alpha} \to C$ along primes. For a fixed prime p,

$$\frac{f_{p^r}}{p^{r\alpha}} = \frac{f_{p^r}}{p^{r\alpha}} - \frac{f_{p^{r-1}}}{p^{(r\ \ 1)\alpha}} \cdot \frac{1}{p^\alpha} \to \left(1 - \frac{1}{p^\alpha}\right) C$$

as $r \to \infty$.

4. Assume that $\frac{f_n^*}{n^\alpha} \to C > 0$. Then $\frac{f_p}{p^\alpha} \to C$ along primes. For fixed prime p and q prime,

$$\frac{f_{pq}}{(pq)^\alpha} = \frac{f_{pq} + f_q + f_p + f_1}{(pq)^\alpha} \to \left(1 + \frac{1}{p^\alpha}\right) C$$

as $q \to \infty$. □

Remark 4.4. For the case $\frac{f_n^*}{n} \to C > 0$ in Theorem 4.3, $\frac{f_n}{n}$ is unbounded: similar arguments show that

$$\frac{f_{p_1 p_2 \ldots p_m}}{p_1 p_2 \cdots p_m} \geq \sum_{i=1}^{m} \frac{1}{p_i} \to \infty$$

as $m \to \infty$.

5. Examples

Few of the standard sequences turn out to be in $\mathcal{E}R$. Here we list a few that are, and one that nearly is. In some cases the proof proceeds by exhibiting a realizing map, in others by proving the congruence. Section 6 contains a table with many sequences from the Encyclopedia in $\mathcal{ER}$; in particular all sequences realized by oligomorphic permutation groups from [2] that fall in $\mathcal{ER}$ are listed.

Example 5.1.

(1) Many trivial sequences are in $\mathcal{ER}$, among them A000004, A000012, A000079 (shifted by one), A000203.

(2) Also A023890, the sum of non-prime divisors, is in $\mathcal{ER}$ since it corresponds to having one orbit of each composite length.

(3) Also A000984 (shifted by one). As pointed out in Example 2.2.4, the sequence of central binomial coefficients $\binom{2n}{n}$ is in $\mathcal{ER}$ for a combinatorial reason. Similarly the sequences of the form $\binom{kn}{jn}$ are all in $\mathcal{ER}$: these include A005809 ($k = 3, j = 1$).

(4) The sequence A001035 (shifted by one) counts the number of distinct posets on n labeled elements. The first 16 terms of this sequence are known, and so the congruence (3) can be verified for $n \leq 16$. However, the sequence is not in $\mathcal{ER}$. We are grateful to Greg Kuperberg for suggesting the following explanation. Write $\mathcal{P}(n)$ for the set of poset structures on $\mathbb{Z}/n\mathbb{Z}$. Then for $d|n$, there is an injection $\phi_{d,n} : \mathcal{P}(d) \to \mathcal{P}(n)$ obtained by pulling back a poset structure using the canonical homomorphism $\mathbb{Z}/n\mathbb{Z} \to \mathbb{Z}/d\mathbb{Z}$. For certain values of n, including all prime values, we claim that those posets that do not appear in the image of one of these injections come in families of size a multiple of n, which gives the congruence (3). by Möbius inversion. Translation gives an action of $\mathbb{Z}/n\mathbb{Z}$ on $\mathcal{P}(n)$; if a

given poset lies on a free orbit then that orbit is the family. In general, suppose that the stabilizer of an orbit is $\mathbb{Z}/(n/d)\mathbb{Z}$, but it is not in the image of $\phi_{d,n}$. Then there is a natural action of the wreath product $\mathbb{Z}/d\mathbb{Z}\mathrm{wr}S_{n/d}$ defined by permuting the points in each coset of $\mathbb{Z}/(n/d)\mathbb{Z}$ and adding a multiple of n/d. If n is the product of two primes (and for many other n) then the size of the orbits of this action are divisible by n. However, at $n = 18$ there are orbits of size ± 6 mod 18, so here we expect the congruence (3) to fail.

(5) The sequence A001945: $1, 1, 1, 5, 1, 7, 8, 5, 19, \ldots$ is in $\mathcal{E}R$ since it counts the periodic points in the automorphism of the 3-torus given by the matrix $\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$. This sequence has been studied computationally for prime appearances (see [4]) and it comes from the cubic polynomial with smallest Mahler measure (see [6]).

(6) The large class of elliptic divisibility sequences (see [5]) and Somos sequences seem never to fall in $\mathcal{ER}$.

(7) Three interesting sequences that seem to be in $\mathcal{ER}$ are the Euler sequence A000364 and the sequences A006953, A006954 connected with the Bernoulli numbers.

Example 5.2. Sequences in $\mathcal{ER}$ arise from the combinatorics of an iterated map. It is a natural question to ask what an orbit of **ORBIT** looks like, and whether there are any asymptotic properties associated to it. The simplest orbit starts with the unit sequence A000007. Applying **ORBIT** iteratively to this gives the following sequence of sequences (in each case, the sequence counts the number of periodic points in a map which has the number of orbits of length n given by the nth entry in the previous sequence).

$1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0$, (*A000007*)

$1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1$ (*A000012*)

$1, 3, 4, 7, 6, 12, 8, 15, 13, 18, 12, 28, 14, 24, 24, 31, 18, 39, 20$ (*A000203*)

$1, 7, 13, 35, 31, 91, 57, 155, 130, 217, 133, 455, 183, 399, 403$ (*A001001*)

$1, 15, 40, 155, 156, 600, 400, 1395, 1210, 2340, 1464, 6200, 2380, 6000$

$1, 31, 121, 651, 781, 3751, 2801, 11811, 11011, 24211, 16105, 78771, 30941$

$1, 63, 364, 2667, 3906, 22932, 19608, 97155, 99463, 246078, 177156$

$1, 127, 1093, 10795, 19531, 138811, 137257, 788035, 896260, 2480437$

$1, 255, 3280, 43435, 97656, 836400, 960800, 6347715, 8069620, 24902280$

$1, 511, 9841, 174251, 488281, 5028751, 6725601, 50955971, 72636421$

$1, 1023, 29524, 698027, 2441406, 30203052, 47079208, 408345795$

$1, 2047, 88573, 2794155, 12207031, 181308931, 329554457, 3269560515$

$1, 4095, 265720, 11180715, 61035156, 1088123400, 2306881200$

$1, 8191, 797161, 44731051, 305175781, 6529545751, 16148168401$

$1, 16383, 2391484, 178940587, 1525878906, 39179682372, 113037178808$

$1, 32767, 7174453, 715795115, 7629394531, 235085301451$

$1, 65535, 21523360, 2863245995, 38146972656, 1410533397600$

The arithmetic and growth properties of these sequences will be explored elsewhere. The sequence of first, second and third terms comprise A000012, A000225, and A003462 respectively.

6. Summary

Being exactly realizable is a strong symmetry property of an integer sequence. In this table we summarize the sequences from the Encyclopedia found to be exactly realizable, together with the corresponding sequence counting the orbits, and any other information. All the sequences are expected to have realizing maps – the inclusion of a map means that we know of a map that is natural in some sense (for example, has a finite description or is algebraic). Direct proofs of the congruence are cited in some brief fashion – a question mark indicates that we do not know a proof and seek one, e means it is easy, and a combinatorial counting problem suggests why the number of orbits is a non-negative integer. The combinatorial counting problems and maps are labelled as follows.

- POLY: the orbits count the number of irreducible polynomials over a finite field.
- NECK(k): the orbits count the number of aperiodic necklaces with n beads in k colours.
- NECK: the orbits count a family of necklaces with constraint – see the encyclopedia entry for details.
- KUMMER: follows from the Kummer and von Staudt congruences.
- COMB: follows from standard combinatorics arguments.
- CHK: the orbit sequence is a 'CHK' transform.
- S(1):S-integer map with $\xi = 2, S = \{2, 3\}, k = \mathbb{Q}$.
- S(2):S-integer map with $\xi = t, S = \{t + 1\}, k = \mathbb{F}_2(t)$.
- R: irrational circle rotation.

Of course there are often many ways to fill in the last column. If there is a natural realizing map, then that fact in itself is usually the best

proof of the congruence. Sequences marked with a question mark in the first column are not known to be in $\mathcal{ER}$ at all: they just seem to satisfy the congruence for the first twenty or so terms. A star indicates that the initial term of the sequence is shifted by one. Of course any non-negative integer sequence at all can appear in the second column, so the selection here is based on the following arbitrary criterion: either the periodic point sequence or the orbit counting sequence is 'interesting'.

The gcd-sum function

Kevin A. Broughan
University of Waikato, Hamilton, New Zealand
Email address: kab@waikato.ac.nz

Abstract

The gcd-sum is an arithmetic function defined as the sum of the gcd's of the first n integers with n : $g(n) = \sum_{i=1}^{n}(i,n)$. The function arises in deriving asymptotic estimates for a lattice point counting problem. The function is multiplicative, and has polynomial growth. Its Dirichlet series has a compact representation in terms of the Riemann zeta function. Asymptotic forms for values of partial sums of the Dirichlet series at real values are derived, including estimates for error terms.

Keywords: greatest common divisor, Dirichlet series, lattice points, multiplicative, Riemann zeta function, gcd-sum.

1. INTRODUCTION

This article is a study of the gcd-sum function: $g(n) = \sum_{i=1}^{n}(i,n)$. The function arose in the context of a lattice point counting problem, for integer coordinate points under the square root curve. The function is multiplicative and has a derivative-like expression for its values at prime powers. The growth function is $O(n^{1+\epsilon})$ and the corresponding Dirichlet series $G(s)$ converges at all points of the complex plane, except at the zeros of the Riemann

zeta function and the point $s = 2$, where it has a double pole. Asymptotic expressions are derived for the partial sums of the Dirichlet series at all real values of s.

These results may be compared with those of [3, 4, 5] where a different arithmetic class of sums of the gcd are studied, namely those based on $g(n) = \sum_{i,j=1}^{n}(i,j)$ and its generalizations. Note that the functions fail to be multiplicative.

The original lattice point problem which motivated this work is solved using a method based on that of Vinogradov. The result is then compared with an expression found using the gcd-sum.

2. GCD-SUM FUNCTION

The gcd-sum is defined to be

$$g(n) = \sum_{j=1}^{n}(j,n) \tag{1}$$

The function that is needed in the application to counting lattice points, described below, is the function S defined by

$$S(n) = \sum_{j=1}^{n}(2j-1,n) \tag{2}$$

THEOREM 2.1. *The function S and gcd-sum g are related by*

$$S(n) = \begin{cases} g(n) & n \text{ odd} \\ 2g(n) - 4g(\frac{n}{2}) & n \text{ even} \end{cases} \tag{3}$$

Proof. For all $n \geq 1$

$$\sum_{j=1}^{n}(2j,n) + \sum_{j=1}^{n}(2j-1,n) = \sum_{j=1}^{2n}(j,n) = 2g(n) \tag{4}$$

If n is odd,

$$\sum_{j=1}^{n}(2j,n) = \sum_{j=1}^{n}(j,n) = g(n)$$

From this and (4) we obtain the equation $S(n) = g(n)$.

If n is even,

$$\sum_{j=1}^{n}(2j,n) = 2\sum_{j=1}^{n}(j,\frac{n}{2}) = 4g(\frac{n}{2})$$

and again the result follows by (4). ∎

The following theorem gives the value of g at prime powers. Even though a direct proof is possible, we give a proof by induction since it reveals more of the structure of the function.

THEOREM 2.2. *For every prime number p and positive integer $\alpha \geq 1$:*

$$g(p^\alpha) = (\alpha+1)p^\alpha - \alpha p^{\alpha-1} \tag{5}$$

Proof. When $\alpha = 1$:

$$g(p) = (1,p) + (2,p) + \cdots + (p,p) = (p-1) + p = 2p-1$$

Similarly when $\alpha = 2$:

$$\begin{aligned} g(p^2) &= (1,p^2) + (2,p^2) + \cdots + (p,p^2) + (p+1,p^2) + \cdots + (2p,p^2) + \cdots + (p^2,p^2) \\ &= 1 + 1 \cdots + p + 1 + \cdots + p + \cdots + p^2 \\ &= (p^2-p) + p(p-1) + p^2 \\ &= 3p^2 - 2p \end{aligned}$$

Hence the result is true for $\alpha = 1$ and for $\alpha = 2$. Now for any $\alpha \geq 2$:

$$\begin{aligned} g(p^\alpha) &= \sum_{j=1}^{p^{\alpha-1}}(j,p^\alpha) + \sum_{j=p^{\alpha-1}+1}^{p^\alpha-1}(j,p^\alpha) + p^\alpha \\ &= g(p^{\alpha-1}) + p^\alpha + \sum_{j=p^{\alpha-1}+1}^{p^\alpha-1}(j,p^\alpha - 1) \end{aligned}$$

But

$$\begin{aligned} \sum_{j=p^{\alpha-1}+1}^{p^\alpha-1}(j,p^\alpha-1) &= \sum_{j=1}^{p^\alpha-p^{\alpha-1}-1}(j,p^{\alpha-1}) \\ &= \sum_{j=1}^{p^\alpha-p^{\alpha-1}}(j,p^{\alpha-1}) - p^{\alpha-1} \\ &= (p-1)g(p^{\alpha-1}) - p^{\alpha-1} \end{aligned}$$

Hence

$$g(p^\alpha) = p^\alpha - p^{\alpha-1} + pg(p^{\alpha-1})$$

Thus, if we assume for some β that

$$g(p^\beta) = (\beta+1)p^\beta - \beta p^{\beta-1} \ ,$$

then

$$\begin{aligned} g(p^{\beta+1}) &= p^{\beta+1} - p^\beta + pg(p^\beta) \\ &= p^{\beta+1} - p^\beta + p\left[(\beta+1)p^\beta + \beta p^{\beta-1}\right] \\ &= (\beta+2)p^{\beta+1} - (\beta+1)p^\beta \end{aligned}$$

and the result follows by induction. ∎

THEOREM 2.3. *The following expression gives the function g in terms of Euler's totient function ϕ :*

$$g(n) = \sum_{j=1}^{n}(j,n) = n\sum_{d|n}\frac{\phi(d)}{d} \tag{6}$$

Proof. The integer e is equal to the greatest common divisor (j,n) if and only if $e|n$ and $e|j$ and $(\frac{j}{e},\frac{n}{e}) = 1$ for $1 \le j \le n$. Therefore the terms with $(j,n) = e$ are $\phi(\frac{n}{e})$ in number. Grouping terms in the sum for $g(n)$ with value e together, it follows that

$$g(n) = \sum_{e|n} e\phi(\frac{n}{e}) = \sum_{d|n}\frac{\phi(d)}{d/n} = n\sum_{d|n}\frac{\phi(d)}{d}$$

∎

COROLLARY 2.1. *The function g is multiplicative, being the divisor sum of a multiplicative function.*

Note that g is not completely multiplicative, nor does it satisfy any modular style of identity of the form

$$g(n)g(m) = \sum_{d|(m,n)} h(d)g(\frac{mn}{d^2})$$

3. BOUNDS

THEOREM 3.1. *The function g is bounded above and below by the expressions*

$$max(2-\frac{1}{n},\Big(\frac{3}{2}\Big)^{\omega(n)}) \leq \frac{g(n)}{n} \leq 27\Big(\frac{\log n}{\omega(n)}\Big)^{\omega(n)}$$

where n is any positive integer and $\omega(n)$ is the number of distinct prime numbers dividing n.

Proof. The bound

$$g(n)=\sum_{j=1}^{n}(j,n) \geq 1(n-1)+n = 2n-1$$

gives the lower bound

$$2-\frac{1}{n} \leq \frac{g(n)}{n}$$

Now consider

$$\begin{aligned}\frac{g(n)}{n} &= \prod_{p|n}\frac{g(p^\alpha)}{p^\alpha}(\text{by 2.1})\\ &= \prod_{p|n}\Big((\alpha+1)-\frac{\alpha}{p}\Big)(\text{Theorem 2.2})\\ &\geq \prod_{p|n}(2-\frac{1}{p}) \geq \Big(\frac{3}{2}\Big)^{\omega(n)} \text{since } \alpha \geq 1 \text{ and } p \geq 2.\end{aligned}$$

This completes the derivation of the second part of the lower bound.

By equation (5),

$$\frac{g(p^\alpha)}{p^\alpha} = \alpha(1-\frac{1}{p})+1 \leq w\alpha\log p$$

where $w=3$ if $p=2,3,5$ or $w=1$ if $p \geq 7$. Hence, if $p_i \geq 7$ for every i and $n=\prod_{i=1}^{m} p_i^{\alpha_i}$, then

$$\frac{g(n)}{n} \leq \prod_{i=1}^{m}\alpha_i\log p_i = \prod_{i=1}^{m}\log(p_i^{\alpha_i})$$

Now

$$\log n = \sum_{i=1}^{m}\alpha_i\log p_i$$

If f is the monomial function $f(x) = \prod_{i=1}^{m} x_i$ of real variables subject to the constraints $x_i \geq 1$ and $\sum x_i = \alpha$, for some fixed positive real number α, then (using Lagrange multipliers) the maximum value of f is $(\frac{\alpha}{m})^m$ and occurs where each $x_i = \frac{\alpha}{m}$. Hence

$$\frac{g(n)}{n} \leq (\frac{\log n}{m})^m = (\frac{\log n}{\omega(n)})^{\omega(n)}$$

In general, using $\alpha_1 = 1$ if $2 \nmid n$, etc.,

$$\begin{aligned} \frac{g(n)}{n} &\leq 27(\alpha_1 \log p_1)(\alpha_2 \log p_2)(\alpha_3 \log p_3) \prod_{p_i \geq 7} \alpha_i \log p_i \\ &= 27 \prod_{i=1}^{m} \alpha_i \log p_i \\ &\leq 27(\frac{\log n}{\omega(n)})^{\omega(n)} \end{aligned}$$

∎

The upper bound in the expression given by the previous theorem is not very useful, given the extreme variability of $\omega(n)$. A plot of the first 200 values of $g(n)/n$ given in Figure 1 illustrates this variability. The following estimates are more useful in practice.

THEOREM 3.2. *The functions g and S satisfy for all $\epsilon > 0$*

$$g(n) = O(n^{1+\epsilon}) \tag{7}$$
$$S(n) = O(n^{1+\epsilon}). \tag{7}$$

Proof. This follows immediately from Theorem 2.3, since $\phi(d) \leq d$ and the divisor function $d(n) = O(n^{\epsilon})$. ∎

4. DIRICHLET SERIES

Define a Dirichlet series based on the function g:

$$G(s) = \sum_{n=1}^{\infty} \frac{g(n)}{n^s}, \text{for } \sigma = \Re(s) > 2$$

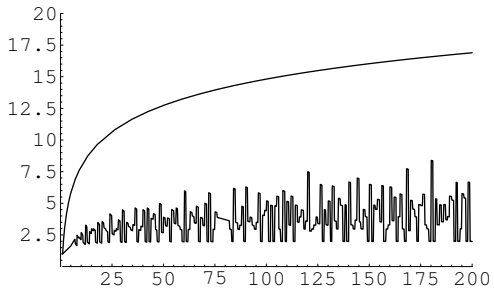

FIG. 1. The functions $g(n)/n$ and n^ϵ

THEOREM 4.1. *The Dirichlet series for $G(s)$ converges absolutely for $\sigma > 2$ and has an analytic continuation to a meromorphic function defined on the whole of the complex plane with value*

$$G(s) = \frac{\zeta(s-1)^2}{\zeta(s)}$$

where $\zeta(s)$ is the Riemann zeta function.

Proof. First write g as a Dirichlet product:

$$g(n) = \sum_{d|n} \phi(d)\frac{n}{d} = (\phi * g)(n)$$

Hence, if $\sigma > 2$,

$$\begin{aligned} G(s) &= (\sum_{n=1}^{\infty} \frac{\phi(n)}{n^s})(\sum_{n=1}^{\infty} \frac{n}{n^s}) \\ &= \zeta(s-1)(\sum_{n=1}^{\infty} \frac{\phi(n)}{n^s}) \end{aligned}$$

But [1]

$$\phi(n) = \sum_{d|n} \mu(d)\frac{n}{d}$$

Therefore

$$\begin{aligned} G(s) &= \zeta(s-1)^2\Big(\sum_{n=1}^{\infty}\frac{\mu(n)}{n^s}\Big) \\ &= \frac{\zeta(s-1)^2}{\zeta(s)} \end{aligned}$$

Since the right hand side is valid on the whole of the complex plane, $G(s)$ has the claimed analytic continuation with a double pole at $s = 2$ and a pole at every zero of $\zeta(s)$. ∎

We now derive asymptotic expressions for the partial sums of this Dirichlet series of g by a method which employs good expressions for Dirichlet series based on Euler's function ϕ, leading to an improvement in the error terms.

If $\alpha \in \mathbb{R}$, define the partial sum function G_α by

$$G_\alpha(x) = \sum_{n\le x}\frac{g(n)}{n^\alpha}$$

LEMMA 4.1. *If $f(x) = O(\log x)$ then $\sum_{n\le x} f(\frac{x}{n}) = O(x)$.*

Proof. This follows easily from the estimate

$$\log(\lfloor x\rfloor!) = x\log x - x + O(\log x)$$

∎

In what follows we define the constant function $h_\alpha(x) = \alpha$ for each real number α.

THEOREM 4.2. *As $x \to \infty$*

$$G_1(x) = \frac{x\log x}{\zeta(2)} + O(x)$$

Proof. By Theorem 2.3, if $f(n) = \phi(n)/n$,

$$\begin{aligned} \frac{g(n)}{n} &= \sum_{d|n}\frac{\phi(d)}{d} \\ &= (h_1 * f)(n) \end{aligned}$$

If we define $F(x) = \sum_{n \leq x} f(n)$ then, by [1],

$$F(x) = \frac{x}{\zeta(2)} + O(\log x)$$

Therefore (using Lemma 5.1 to derive the error estimate)

$$\begin{aligned} G_1(x) &= \sum_{n \leq x} h_1(n) F(\frac{x}{n}) \\ &= \sum_{n \leq x} F(\frac{x}{n}) \\ &= \frac{x}{\zeta(2)}[1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{\lfloor x \rfloor}] + O(x) \\ &= \frac{x}{\zeta(2)}[\log x + \gamma + O(\frac{1}{x})] + O(x) \\ &= \frac{x \log x}{\zeta(2)} + O(x) \end{aligned}$$

∎

THEOREM 4.3. *As $x \to \infty$,*

$$G_0(x) = \frac{x^2 \log x}{2\zeta(2)} + O(x^2)$$

Proof. By Theorem 2.3 with $f(n) = n$:

$$\begin{aligned} g(n) &= \sum_{d|n} \frac{n}{d} \phi(d) \\ &= (f * \phi)(n) \\ &= (\phi * f)(n) \end{aligned}$$

If we define $F(x) = \sum_{n \leq x} n$ then

$$F(x) = \frac{\lfloor x \rfloor (\lfloor x \rfloor + 1)}{2} = \frac{x^2}{2} + O(x)$$

Therefore

$$\begin{aligned} G_0(x) &= \sum_{n\leq x} \phi(n) F(\frac{x}{n}) \\ &= \frac{x^2}{2} \sum_{n\leq x} \frac{\phi(n)}{n^2} + O(x^2) \\ &= \frac{x^2 \log x}{2\zeta(2)} + O(x^2) \end{aligned}$$

∎

LEMMA 4.2. *For all* $\alpha \in \mathbb{R}$

$$G_\alpha(x) = \sum_{n\leq x} n^{1-\alpha} \Phi_\alpha(\frac{x}{n})$$

where

$$\Phi_\alpha(x) = \sum_{n\leq x} \frac{\phi(n)}{n^\alpha}$$

Proof. Define the monomial function $m_\beta(x) = x^{-\beta}$ for all real β and positive x. By Theorem 2.3,

$$\begin{aligned} \frac{g(n)}{n^\alpha} &= \sum_{d|n} \frac{\phi(d)}{d^\alpha} (\frac{n}{d})^{1-\alpha} \\ &= (\phi_\alpha * m_{\alpha-1})(n) \end{aligned}$$

The lemma follows directly from this expression. ∎

Below we derive an asymptotic expression for G_α for all real values of α. This is interesting because of the uniform applicability of the same expression. First we set out some standard estimates [1] which are collected together below for easy reference. Let

$$S_\alpha(x) = \sum_{n\leq x} \frac{1}{n^\alpha}$$

for all positive x and real α. Then

$$
\begin{aligned}
(a)\ \Phi_0(x) &= \frac{x^2}{2\zeta(2)} + O(x\log x)\\
(b)\ \Phi_1(x) &= \frac{x}{\zeta(2)} + O(\log x)\\
(c)\ \Phi_2(x) &= \frac{\log x}{\zeta(2)} + \frac{\gamma}{\zeta(2)} - A + O(\frac{\log x}{x})\\
(d)\ \Phi_\alpha(x) &= \frac{x^{2-\alpha}}{(2-\alpha)\zeta(2)} + \frac{\zeta(\alpha-1)}{\zeta(\alpha)} + O(x^{1-\alpha}\log x), \alpha > 1, \alpha \neq 2\\
(e)\ \Phi_\alpha(x) &= \frac{x^{2-\alpha}}{(2-\alpha)\zeta(2)} + O(x^{1-\alpha}\log x), \alpha \leq 1\\
(A)\ S_1(x) &= \log x + \gamma + O(\frac{1}{x})\\
(B)\ S_\alpha(x) &= \frac{x^{1-\alpha}}{1-\alpha} + \zeta(\alpha) + O(\frac{1}{x^\alpha}), \alpha > 0, \alpha \neq 1\\
(C)\ S_\alpha(x) &= \frac{x^{1-\alpha}}{1-\alpha} + O(\frac{1}{x^\alpha}), \alpha \leq 0
\end{aligned}
$$

where in (c)

$$A = \sum_{n=1}^{\infty} \frac{\mu(n)\log n}{n^2} \approxeq -0.35$$

Note that there are better estimates for the error terms, for (a) $O(x\log^{\frac{2}{3}} x(\log\log x)^{1+\epsilon})$ [8] and for (b) $O(\log^{\frac{2}{3}} x(\log\log x)^{\frac{4}{3}})$ [9] but, since these are only available for $\alpha = 0$ and $\alpha = 1$ we do not use them.

Even though there is a wide diversity of expressions in this set, a very similar expression holds for $G_\alpha(x)$, for all real values of α, except $\alpha = 2$ which corresponds to the pole of $G(s)$:

THEOREM 4.4. *If $\alpha < 2$:*

$$G_\alpha(x) = \frac{x^{2-\alpha}\log x}{(2-\alpha)\zeta(2)} + O(x^{2-\alpha}),$$

if $\alpha = 2$:

$$G_2(x) = \frac{\log^2 x}{2\zeta(2)} + O(\log x)$$

and if $\alpha > 2$:

$$G_\alpha(x) = \frac{x^{2-\alpha}\log x}{(2-\alpha)\zeta(2)} + \frac{\zeta(\alpha-1)^2}{\zeta(\alpha)} + O(x^{2-\alpha}).$$

Proof.
Case 0: Let $\alpha = 0$. The stated result is given by Theorem 5.4 above.
Case 1: Let $\alpha = 1$. The result is given by Theorem 5.3.
Case 2: Let $\alpha = 2$.

$$\begin{aligned}
G_2(x) &= \sum_{n\le x} n^{-1}\Phi_2(\frac{x}{n}) \\
&= \sum_{n\le x}\frac{\log(\frac{x}{n})}{n\zeta(2)} + (\frac{\gamma}{\zeta(2)} - A)\sum_{n\le x} n^{-1} + \sum_{n\le x} O\big(n^{-1}\frac{\log(\frac{x}{n})}{x/n}\big) \\
&= \frac{\log x}{\zeta(2)}(\sum_{n\le x}\frac{1}{n}) - \frac{1}{\zeta(2)}\sum_{n\le x}\frac{\log n}{n} + (\frac{\gamma}{\zeta(2)} - A)(\sum_{n\le x}\frac{1}{n}) + O(1) \\
&= [\frac{\log x}{\zeta(2)} + \frac{\gamma}{\zeta(2)} - A][\log x + \gamma + O(\frac{1}{x})] - \frac{1}{\zeta(2)}[\frac{\log^2 x}{2} + A_1 + O(\frac{\log x}{x})] + O(1) \\
&= \frac{\log^2 x}{2\zeta(2)} + \log x[\frac{2\gamma}{\zeta(2)} - A] + O(1)
\end{aligned}$$

Case 3: If $\alpha < 1$ we have

$$\begin{aligned}
G_\alpha(x) &= \sum_{n\le x}\frac{1}{n^{\alpha-1}}\Phi_\alpha(\frac{x}{n}) \\
&= \sum_{n\le x}\frac{1}{n^{\alpha-1}}\frac{x^{2-\alpha}}{n^{2-\alpha}(2-\alpha)\zeta(2)} + \sum_{n\le x} O\big(x^{1-\alpha}\log(\frac{x}{n})\big) \\
&= \frac{x^{2-\alpha}}{(2-\alpha)\zeta(2)}(\sum_{n\le x}\frac{1}{n}) + O(x^{2-\alpha}) \\
&= \frac{x^{2-\alpha}}{(2-\alpha)\zeta(2)}[\log x + \gamma + O(\frac{1}{x})] + O(x^{2-\alpha}) \\
&= \frac{x^{2-\alpha}\log x}{(2-\alpha)\zeta(2)} + O(x^{2-\alpha})
\end{aligned}$$

Case 4: Finally, if $\alpha > 1$ and $\alpha \neq 2$:

$$\begin{aligned}
G_\alpha(x) &= \sum_{n\le x} \frac{1}{n^{\alpha-1}} \Phi_\alpha(\frac{x}{n}) \\
&= \sum_{n\le x} \frac{1}{n^{\alpha-1}} [\frac{x^{2-\alpha}}{n^{2-\alpha}(2-\alpha)\zeta(2)} + \frac{\zeta(\alpha-1)}{\zeta(\alpha)} + O(\frac{x^{1-\alpha}}{n^{1-\alpha}} \log(\frac{x}{n}))] \\
&= \frac{x^{2-\alpha}}{(2-\alpha)\zeta(2)} (\sum_{n\le x} \frac{1}{n}) + \frac{\zeta(\alpha-1)}{\zeta(\alpha)} (\sum_{n\le x} \frac{1}{n^{\alpha-1}}) + O(x^{2-\alpha}) \\
&= \frac{x^{2-\alpha}}{(2-\alpha)\zeta(2)} [\log x + \gamma + O(\frac{1}{x})] \\
&\quad + \frac{\zeta(\alpha-1)}{\zeta(\alpha)} [\frac{x^{2-\alpha}}{2-\alpha} + \zeta(\alpha-1) + O(x^{1-\alpha})] + O(x^{2-\alpha}) \\
&= \frac{x^{2-\alpha} \log x}{(2-\alpha)\zeta(2)} + \frac{\zeta(\alpha-1)^2}{\zeta(\alpha)} + O(x^{2-\alpha})
\end{aligned}$$

∎

For $\alpha \in \{0, 1, 2\}$ we can improve these asymptotic expressions by deriving an additional term and a smaller error. This has already been done for $\alpha = 2$. In both of the remaining cases we use the following useful, and again elementary, device [1]: If $ab = x$, $F(x) = \sum_{n\le x} f(n)$ and $H(x) = \sum_{n\le x} h(n)$ then

$$\sum_{e,d\le x} f(e)h(d) = \sum_{n\le a} f(n)H(\frac{x}{n}) + \sum_{n\le b} h(n)F(\frac{x}{n}) - F(a)H(b)$$

in the special case $a = b = \sqrt{x}$.

THEOREM 4.5.

$$G_1(x) = \frac{x \log x}{\zeta(2)} + x[\frac{2\gamma}{\zeta(2)} - A - \frac{1}{\zeta(2)}] + O(\sqrt{x} \log x)$$

Proof. First rewrite $G_1(x)$:

$$\begin{aligned}
G_1(x) &= \sum_{n\le x} \Phi_1(\frac{x}{n}) \text{ (by Lemma 4.2)} \\
&= \sum_{n\le x} \sum_{m\le x/n} \frac{\phi(n)}{n} \\
&= \sum_{e,d\le x} \frac{\phi(d)}{d} 1.
\end{aligned}$$

Now let F and H be defined by

$$\begin{aligned} F(x) &= \sum_{n\le x} \frac{\phi(n)}{n} = \frac{x}{\zeta(2)} + O(\log x) \\ H(x) &= \sum_{n\le x} 1 = \lfloor x \rfloor \end{aligned}$$

Using the device described above, rewrite G_1 in terms of F and H:

$$\begin{aligned} G_1(x) &= \sum_{n\le\sqrt{x}} \frac{\phi(n)}{n} H(\frac{x}{n}) + \sum_{n\le\sqrt{x}} F(\frac{x}{n}) - F(\sqrt{x})H(\sqrt{x}) \\ &= \sum_{n\le\sqrt{x}} \frac{\phi(n)}{n}[\frac{x}{n} + O(1)] + \sum_{n\le\sqrt{x}} [\frac{x}{n\zeta(2)} + O(\log(\frac{x}{n}))] \\ &\quad -(\frac{\sqrt{x}}{\zeta(2)} + O(\log(x)))(\sqrt{x} + O(1)) \\ &= x \sum_{n\le\sqrt{x}} \frac{\phi(n)}{n^2} + O(\sum_{n\le\sqrt{x}} \frac{\phi(n)}{n}) + \frac{x}{\zeta(2)} \sum_{n\le\sqrt{x}} \frac{1}{n} \\ &\quad +O(\sqrt{x}\log x) + O(\sum_{n\le\sqrt{x}} \log n) - \frac{x}{\zeta(2)} + O(\sqrt{x}\log x) \\ &= x[\frac{\log x}{2\zeta(2)} + \frac{\gamma}{\zeta(2)} - A + O(\frac{\log(x)}{\sqrt{x}}] + O(\sqrt{x}) \\ &\quad +\frac{x}{\zeta(2)}[\log\lfloor\sqrt{x}\rfloor + \gamma + O(\frac{1}{\sqrt{x}})] \\ &\quad +O(\sqrt{x}\log x) + O(\log[\sqrt{x}]!) - \frac{x}{\zeta(2)} \\ &= \frac{x\log x}{\zeta(2)} + x[\frac{2\gamma}{\zeta(2)} - A - \frac{1}{\zeta(2)}] + O(\sqrt{x}\log x). \end{aligned}$$

∎

THEOREM 4.6.

$$G_2(x) = \frac{\log^2 x}{2\zeta(2)} + \log x[\frac{2\gamma}{\zeta(2)} - A] + O(1)$$

Proof. See the proof of Theorem 5.4, case 2 above. ∎

THEOREM 4.7.

$$G_0(x) = \frac{x^2 \log x}{2\zeta(2)} + \frac{x^2 \zeta(2)^2}{2\zeta(3)} + O(x^{3/2} \log x)$$

Proof. First we state four estimates:

(1) $G_1(x) = \sum_{n \le x} \frac{g(n)}{n} = \frac{x \log x}{\zeta(2)} + O(x)$ (Theorem 4.2)

(2) $F(x) = \sum_{n \le x} n = \frac{x^2}{2} + O(x)$

(3) $\sum_{n \le x} \log n = x \log x + O(x)$

(4) $G_3(x) = \frac{\zeta(2)^2}{\zeta(3)} + O(\frac{\log x}{x})$ (by Theorem 4.4)

Expand G_0 using $f(n) = n$ and $h(n) = g(n)/n$ so $H = G_1$:

$$\begin{aligned}
G_0(x) &= \sum_{n \le x} g(n) = \sum_{n \le x} \frac{g(n)}{n} n \\
&= \sum_{n \le \sqrt{x}} \frac{g(n)}{n} F(\frac{x}{n}) + \sum_{n \le \sqrt{x}} n G_1(\frac{x}{n}) - F(\sqrt{x}) G_1(\sqrt{x}) \\
&= \sum_{n \le \sqrt{x}} \frac{g(n)}{n} [\frac{x^2}{2n^2} + O(\frac{x}{n})] + \sum_{n \le \sqrt{x}} n [\frac{\frac{x}{n} \log \frac{x}{n}}{\zeta(2)} + O(\frac{x}{n})] \\
&\quad -(\frac{x}{2} + O(\sqrt{x}))(\frac{\sqrt{x} \log x}{2\zeta(2)} + O(\sqrt{x})) \text{ (by (1) and (2))} \\
&= \frac{x^2}{2} \sum_{n \le \sqrt{x}} \frac{g(n)}{n^3} + O(\sum_{n \le \sqrt{x}} \frac{g(n)}{n^2}) + \frac{x \log x}{\zeta(2)} \sum_{n \le \sqrt{x}} 1 \\
&\quad -\frac{x}{\zeta(2)} \sum_{n \le \sqrt{x}} \log n + O(x \sum_{n \le \sqrt{x}} 1) - \frac{x^{3/2} \log x}{4\zeta(2)} + O(x^{3/2}) \\
&= \frac{x^2}{2} G_3(\sqrt{x}) + O(\log^2 x) + \frac{x^2 \log x}{2\zeta(2)} + O(x^{3/2} \log x) \\
&\quad -\frac{x}{\zeta(2)} [\frac{\sqrt{x} \log x}{2} + O(\sqrt{x})] + O(x^{3/2}) - \frac{x^{3/2} \log x}{4\zeta(2)} + O(x^{3/2}) \text{ (by (3))}
\end{aligned}$$

Therefore

$$\begin{aligned} G_0(x) &= \frac{x^2}{2}[\frac{\zeta(2)^2}{\zeta(3)} + O(\frac{\log x}{\sqrt{x}})] + \frac{x^2 \log x}{2\zeta(2)} \\ &\quad -\frac{x}{\zeta(2)}[\frac{\sqrt{x}\log x}{2} + O(\sqrt{x})] \\ &\quad -\frac{x^{3/2}\log x}{4\zeta(2)} + O(x^{3/2}\log x) \text{ (using (4))} \\ &= \frac{x^2 \log x}{2\zeta(2)} + \frac{x^2\zeta(2)^2}{2\zeta(3)} + O(x^{3/2}\log x) \end{aligned}$$

∎

5. APPLICATION

Consider the problem of counting the integer lattice points in the first quadrant in the square $[0, R] \times [0, R]$ and under the curve $y = \sqrt{Rx}$ as $R \to \infty$.

Let $R = n^2$ and count lattice points by adding those in trapezia under the curve. If T is a trapezium with integral coordinates for each vertex $(0, 0), (b, 0), (0, \alpha)$, and (b, β), then by Pick's theorem [6] the area is equal to the number of interior points plus one half the number of interior points on the edges plus one. From this it follows that the total number of interior lattice points is given by the expression

$$\frac{1}{2}[(b-1)(\alpha+\beta) - b - (b, \beta - \alpha) + 2]$$

where (u, v) is the greatest common divisor.

We approximate the region under the curve $y = n\sqrt{x}$ and above the interval $[0, n^2]$ by n trapezia with the j-th having the base $[(j-1)^2, j^2]$. Divide the lattice points inside and on the boundary of these trapezia into five sets:

$$\begin{aligned} L_1 &= \#\{\text{interior points of trapezia}\} \\ L_2 &= \#\{\text{interior points of vertical sides}\} \\ L_3 &= \#\{\text{interior points of the top sides}\} \\ L_4 &= \#\{\text{interior points of the bottom sides}\} \\ L_5 &= \#\{\text{vertices of all trapezia}\} \end{aligned}$$

Then

$$\begin{aligned}
L_1 &= \sum_{j=1}^{n} \frac{1}{2}[(2j-1)(nj+n(j-1)) - (2j-1) - n(j-1) - nj - (2j-1,n) + 2] \\
L_2 &= \sum_{j=1}^{n-1} nj - 1 = \frac{n^3}{2} - \frac{n^2}{2} - n + 1 \\
L_3 &= \sum_{j=1}^{n} [(n, 2j-1) - 1] = S(n) - n \text{ where } S \text{ is defined in (2)} \\
L_4 &= \sum_{j=1}^{n} 2j - 2 = n^2 - n \\
L_5 &= 2n + 1
\end{aligned}$$

Hence if $N_1(R)$ represents the total number of lattice points,

$$\begin{aligned}
N_1(R) &= L_1 + L_2 + L_3 + L_4 + L_5 \\
&= \frac{2}{3}n^4 - \frac{1}{6}n^2 + \frac{1}{2}S(n) \\
N_1(n^2) &= \frac{2}{3}n^4 - \frac{1}{6}n^2 + O(n^{\frac{1}{2}+\epsilon})
\end{aligned}$$

by Theorem 3.2.

It is interesting to note that the area of the gap between the curve and the trapezia is exactly $\frac{1}{6}n^2$.

The total number of points in the trapezia is of course less than the number under the curve. There are n trapezia, the j-th having width $2j-1$. The maximum distance from the top of the j-th trapezia to the curve is $n/4(2j-1)$, so the number of additional points is $O(n^2)$. This leads to the estimate

$$N_2(n^2) = \frac{2}{3}n^4 + O(n^2)$$

for the number N_2 of lattice points under the curve.

Now a more accurate estimate for N_2 is derived. First the method of Vinogradov [7] is used to count the fractional parts of the inverse function $x = y^2/R$:

Let $b - a \ll A$ where $A \gg 1$. Let f be a function defined on the positive real numbers with f'' continuous, $0 < f'(x) \ll 1$ and having $f''(x) \gg \frac{1}{A}$. Then

$$\sum_{a<u\leq b}\{f(u)\} = \frac{b-a}{2} + O(A^{\frac{2}{3}})$$

If $A = n$, $f(u) = u^2/n$, and $f''(u) = 2/n \gg A^{-1}$ then it follows that

$$\sum_{0<u\leq n}\{f(u)\} = \frac{n}{2} + O(n^{\frac{2}{3}})$$

Hence the number of lattice points $M(n)$ under or on the inverse function curve is

$$\begin{aligned} M(n) &= \sum_{j=1}^{n}\lfloor\frac{j^2}{n}\rfloor + n + 1 \\ &= \sum_{j=1}^{n}\frac{j^2}{n} - \sum_{j=1}^{n}\{\frac{j^2}{n}\} + n + 1 \\ &= \frac{1}{6}(n+1)(2n+1) + \frac{n}{2} + O(n^{\frac{2}{3}}) \end{aligned}$$

So if $N_2(n)$ represents the number of lattice points strictly under the curve $y = \sqrt{Rx}$ when $R = n$, then

$$\begin{aligned} N_2(n) &= (n+1)^2 - \frac{1}{6}(n+1)(2n+1) - \frac{n}{2} + O(n^{\frac{2}{3}}) \\ &= \frac{2}{3}n^2 + n + O(n^{\frac{2}{3}}) \end{aligned}$$

The number of lattice points on the curve is $O(n^{\frac{1}{2}})$, so does not change this estimate.

ACKNOWLEDGMENT

This work was done in part while the author was on study leave at Columbia University. The support of the Department of Mathematics at Columbia University and the valuable discussions held with Patrick Gallagher are warmly acknowledged.

Abstract

A prime Pythagorean triangle has three integer sides of which the hypotenuse and one leg are primes. In this article we investigate their properties and distribution. We are also interested in finding chains of such triangles, where the hypotenuse of one triangle is the leg of the next in the sequence. We exhibit a chain of seven prime Pythagorean triangles and we include a brief discussion of primality proofs for the larger elements (up to 2310 digits) of the associated set of eight primes.

1991 *Mathematics Subject Classification*: Primary 11A41
Keywords: Pythagorean triangles, prime numbers, primality proving

1. Introduction

While investigating the distribution of special forms of primes, the first author accidently came across a conjecture about Pythagorean triangles (right triangles with integral sides). The conjecture, based on the famous Conjecture (H) of Sierpiński and Schinzel, states that there is an infinite number of Pythagorean triangles which have a leg and hypotenuse both prime [9, page 408].

Pythagorean triangles have been the subject of much recreational material [1] as well as the basis of some of the most important and fundamental topics in number theory. However, we could not find any significant references to such two-prime Pythagorean triangles, and hoping that we had found a new topic to study we enthusiastically started

(1) developing appropriate theory and computer programs;
(2) searching for large two-prime triangles;
(3) searching for sequences of two-prime triangles where the hypotenuse of the previous triangle becomes the leg of the next one.

The largest two-prime Pythagorean triangle that was found had a leg of 5357 digits and an hypotenuse of 10713 digits. It soon became apparent that finding sequences of triangles was exceptionally interesting and challenging. Eventually a sequence of seven triangles was found. More significant than the seven triangles is the improvement by the second author of the general method, APRCL, for primality proving so that the seventh hypotenuse of 2310 digits could be proved prime.

2. Theory

A two-prime Pythagorean triangle, $A^2 + B^2 = C^2$, must be primitive, so that

$$A = u^2 - v^2, \qquad B = 2uv, \qquad C = u^2 + v^2,$$

with $\gcd(u, v) = 1$, and u, v of different parity. Since $A = (u + v)(u - v)$, for A to be prime it is necessary that $(u - v) = 1$ so that

$$A = 2v + 1, \qquad B = 2v^2 + 2v, \qquad C = 2v^2 + 2v + 1.$$

Thus

$$C = \frac{A^2 + 1}{2}. \tag{2.1}$$

Note that the even leg is only one less than the hypotenuse. The triangles get quite thin as A increases.

To find two-prime Pythagorean triangles it is necessary to find pairs of primes A, C that satisfy the above equation. Table 1 lists the smallest two-prime Pythagorian triangles.

Table 1. Pythagorean triangles with two prime sides

rank	prime leg	even leg	hypotenuse
1	3	4	5
2	5	12	13
3	11	60	61
4	19	180	181
5	29	420	421
6	59	1740	1741
7	61	1860	1861
8	71	2520	2521
9	79	3120	3121
10	101	5100	5101
100	4289	9197760	9197761
1000	91621	4197203820	4197203821

Small triangles are easy to find by a simple search, but finding large triangles with thousands of digits is complicated by the difficulty of proving true primality

of the hypotenuse, C. However, if $(C-1)$ has many factors then it is easy to prove primality using [2], assuming that the factored part of $(C-1)$ exceeds $\sqrt[3]{C}$. Since

$$C-1=\frac{A^2+1}{2}-1=(A^2-1)/2=(A-1)(A+1)/2, \tag{2.2}$$

by picking an appropriate form for A, then $(A-1)$ can be completely factored so that $(C-1)$ will be about 50% factored.

Using the form $A=k\cdot 10^n+1$, a computer search of a few days gave the following large triangle:

$$A=491140\cdot 10^{1300}+1, \quad 1306 \text{ digits}, \qquad C=2612 \text{ digits}.$$

A few days after this result was posted to the NMBRTHRY list we received a message from Iago Camboa announcing a much larger triangle:

$$A=1491\cdot 2^{17783}+1, \quad 5357 \text{ digits}, \qquad C=10713 \text{ digits}.$$

He cleverly used a previously computed list of primes as a source for A thus eliminating the large amount of time required to find the first prime.

3. Two-prime Pythagorean triangle sequences

It is possible to find a series of primes, $P_0, P_1, P_2, ..., P_k, ..., P_n$ such that

$$P_{k+1}=\frac{P_k^2+1}{2}. \tag{3.1}$$

This represents a sequence of n two-prime triangles where P_k is the hypotenuse of the k-th triangle and the leg of the $(k+1)$-th triangle. Each P has about twice the number of digits as the previous P. Table 2 is a list of the smallest sets of two sequential prime Pythagorean triangles.

Table 2. Two sequential prime Pythagorean triangles

	triangle 1			triangle 2		
1	3	4	5	5	12	13
2	11	60	61	61	1860	1861

8	929	431520	431521	431521	93105186720	93105186721

Table 3 is a list of the starting primes for the smallest prime Pythagorean sequences for two, three, four and five triangles. These were found by straight forward unsophisticated searching and took about 10 computer-days (Pentium/200), mostly for finding five triangles.

Finding the starting prime for the smallest prime sequence of six triangles took about 120 computer days.

P_0 for 6 triangles = 2500282512131.

TABLE 3. Starting prime for smallest prime Pythagorean sequences

20	4691	502501	86569771	59564407571

Next, we attempted to derive the number of n triangle sequences that could be expected. If the $(n+1)$ numbers that make up the n triangles were selected randomly but were of the proper size then the probability that P is the start of n triangles is

$$Q(P,n) = \prod_{0}^{n} \frac{1}{\log P_i} = \prod_{0}^{n} \frac{1}{2^i (\log P)} = \frac{1}{2^{n(n+1)/2} (\log P)^{n+1}}. \tag{3.2}$$

However, there are correlations between the primes that affect the prime probabilities. It is easy to show from equation (2.1) that P_0 can only end in 1 or 9, which elininates half the possible P_0's, and assures that all subsequent potential primes cannot be divisible by 2, 3 or 5. Thus, the probability of each subsequent number being prime is increased by the factor $(2/1)(3/2)(5/4) = 3.75$. The probability that P is the start of n prime triangles now becomes,

$$Q(P,n) = \frac{0.5(3.75)^n}{2^{n(n+1)/2} (\log P)^{n+1}}. \tag{3.3}$$

The expected number of prime triangles up to a given P_0 is

$$E(P_0,n) = \sum_{P=3}^{P_0} Q(P,N) = \frac{0.5(3.75)^n}{2^{n(n+1)/2}} \sum_{P=3}^{P_0} \frac{1}{(\log P)^{n+1}}. \tag{3.4}$$

The last summation can be approximated by an integral, which after integrating by parts becomes,

$$R(P,n) = \frac{1}{n!}Li(P) - \frac{1}{n!}\frac{P}{\log P} - \cdots - \frac{1}{n(n-1)}\frac{P}{(\log P)^{(n-1)}} - \frac{1}{n}\frac{P}{(\log P)^n},$$

where $Li(P)$ is the logarithmic integral. Equation (3.4) now becomes

$$E(P_0,n) = \frac{0.5(3.75)^n}{2^{n(n+1)/2}}R(P_0,n)(1.3)^n \ . \tag{3.5}$$

Note the inclusion of a correction factor, $(1.3)^n$. As is discussed in the following section on sieving, there are other correlations between the primes which affect the expectation. These are difficult to derive theoretically so we determined it empirically. Table 4 compares the estimated and actual number of triangles found. The corrected estimate appears adequate to assist in estimating the search time for seven prime Pythagorean triangles.

TABLE 4. Estimated and actual number of prime Pythagorean triangles

triangles n	P_0	actual	estimate	corrected estimate
1	130000	1302	1090	1420
2	1980000	1005	741	1252
3	10^8	953	469	1030
4	$18 \cdot 10^8$	205	53	151
5	$63 \cdot 10^9$	21	4	15
6	$28 \cdot 10^{12}$	1	0.14	0.7

Next, we use equation (3.5) to estimate the smallest P_0 that will give seven triangles. The following table shows we can expect that P_0 for seven triangles will be about 6700 times larger than P_0 for six triangles. Using performance data from the search for six triangles, this means that the search for the smallest sequence of seven prime Pythagorean triangles could be expected to take about 200 computer-years!

n	P_0 for expectation=1	actual P_0
2	28	3
3	1,350	271
4	1,000,000	169, 219
5	$1.5 \cdot 10^9$	$3.5 \cdot 10^8$
6	$4.0 \cdot 10^{12}$	$2.5 \cdot 10^{12}$
7	$2.7 \cdot 10^{16}$	

It was clear that the search for the smallest sequence of seven triangles as presently constituted was impractical. For every P_0 the search method included testing by division to see if each of the $(n+1)$ potential primes was free of small factors. The second author then proposed an efficient sieving method that limited the search to sequences that had a high probability of success. This made a search for seven triangles reasonable.

4. The Sieve

A set of seven Pythagorean triangles with the desired properties is equivalent to a chain of eight primes, $P_0, P_1, \ldots, P_7$, linked by the condition $P_{i+1} = (P_i^2 + 1)/2$, $i = 0, 1, \ldots, 6$.

The purpose of the sieve is to eliminate from further consideration numbers P_0 for which either P_0 itself or one of the numbers P_i, $i = 1, 2, \ldots, 7$, is divisible by a small prime. Let q be an odd prime and suppose P is to be considered as a possible value of P_0. Clearly, we can reject P if $P \equiv 0 \pmod{q}$. Furthermore, we can reject P if P_1 is divisible by q, that is, if

$$P \equiv \sqrt{-1} \pmod{q},$$

on the assumption that $\left(\frac{-1}{q}\right) = 1$. Continuing in this way, we can reject P if

$$P \equiv \sqrt{2\sqrt{-1} - 1} \pmod{q}$$

(for then P_2 is divisible by q), or if

$$P \equiv \sqrt{2\sqrt{2\sqrt{-1} - 1} - 1} \pmod{q},$$

and so on, provided that the various square roots $\pmod{q}$ exist. In each case, where there is a square root $\pmod{q}$ there are two possible values and hence two extra residues $\pmod{q}$ that can be eliminated.

For prime q, we compute the set $E(q)$ of forbidden residues $\pmod{q}$ as follows. Start with $E_0(q) = \{0\}$. Given $E_i(q)$, let

$$E_{i+1} = \left\{ \pm\sqrt{2e - 1} \pmod{q} : e \in E_i \text{ and } \left(\frac{2e-1}{q}\right) = 1 \right\}.$$

Then $E(q)$ is the union of $E_0(q)$, $E_1(q)$, $\ldots$, $E_7(q)$. In Table 5 we list $E(q)$ for the first few primes $q \equiv 1 \pmod{4}$.

Now let

$$P = NQ + H,$$

where Q is the product of small primes and H is allowed to run through all the permitted residues $\pmod{Q}$. We sieve the numbers N. That is, we start with an interval $N_0 \le N < N_1$ and for each sieving prime q, $\gcd(q, Q) = 1$, we remove all those $N \in [N_0, N_1)$ for which $NQ + H$ is divisible by q.

We split Q into pairwise coprime divisors m_0, m_1, $\ldots$, m_r. For each divisor m_j of Q, $j = 0, 1, \ldots, r$, we make a list of the permitted residues $\pmod{m_j}$; h is a permitted residue $\pmod{m_j}$ if h is not zero $\pmod{m_j}$ and if the function $h \to (h^2 + 1)/2 \pmod{m_j}$ does not produce zero $\pmod{m_j}$ during the first seven iterations. The permitted residues $H \pmod{Q}$ are constructed from permitted residues $h \pmod{m_j}$ using the Chinese Remainder Theorem. It works well if Q is the product of primes which have small percentages of permitted residues. From this perspective the best primes, in descending order of merit, turn out to be: 29 (34%), 5 (40%), 2 (50%), 17 (59%), 13 (62%), 3 (67%), 53 (68%), 101 (71%), 89 (74%) and 233 (77%).

For the actual search we chose $Q = 21342962305470$, with divisors $6630 = 2 \cdot 3 \cdot 5 \cdot 13 \cdot 17$, 29, 89, 101, 53, and 233. The number of values of $H \pmod{Q}$ turns out to be $320 \cdot 10 \cdot 66 \cdot 72 \cdot 36 \cdot 180 = 98537472000$, the indicated factors of this product being the numbers of permitted residues modulo the corresponding factors of Q.

The construction of the sieve and the method of computing $H \pmod{Q}$ were based on computer programs designed for finding prime k-tuplets; see [6] for the details. We set up a table of sieving primes q together with pre-computed values of $-1/Q \pmod{q}$ as well as, for $q \equiv 1 \pmod 4$, $e/Q \pmod{q}$ for each pair e, $q-e$ in $E(q)$. We can then rapidly calculate the index of the first N to be removed from the sieve array for $P \equiv e \pmod{q}$: $e/Q - H/Q - N_0 \pmod{q}$.

The program also allows us to limit the size of primes $q \equiv 3 \pmod 4$ used by the sieve. One reason for doing so would be to give priority to primes $q \equiv 1 \pmod 4$; they have more residues for sieving and therefore one would expect them to be in some sense more efficient. In fact it was found by experiment that if P has about 19 digits, a sieve limit $L_0 = 20000$ for $q \equiv 3 \pmod 4$ and 480000 for $q \equiv 1 \pmod 4$ was approximately optimal.

Further performance improvements are possible by limiting the influence of primes $q \equiv 1 \pmod 4$. For each P that survives the sieve we do a probable-primality test, $2^P \equiv 2 \pmod P$, on P as well as, if P turns out to be a probable-prime, the numbers that follow P in the chain, stopping as soon as a composite is found. The effort required to perform the probable-primality test increases by a factor of about eight as we move from P_i to P_{i+1}. Therefore it might be better if priority were given to sieving primes q and residues $e \pmod q$ which would eliminate composite numbers from the larger elements of the chain.

For controlling the effect of primes $q \equiv 1 \pmod 4$ we provided a set of parameters $L_1, L_2, \ldots$. If $q \equiv 1 \pmod 4$ is a sieving prime and $e \in E_i(q)$ then we do not use residue $e \pmod q$ for sieving unless $q < L_i$. As a result of a certain amount of experimentation we found that the optimum sieving rate occurs with the limits set approximately as follows: $L_1 = 120000$, $L_2 = 240000$, $L_3 = 360000$, together with a limit $L_0 = 20000$ for primes $\equiv 3 \pmod 4$ and an overall sieve limit of 480000. From these values we can compute an expected survival rate of

$$\prod_{q \text{ prime}} \frac{q - \nu_q}{q} = \frac{1}{3770},$$

approximately, where ν_q is the number of residues $\pmod q$ used by the sieve.

5. Eight Primes

In September 1999 the search was successful and this chain of eight probable primes was found:

$$\begin{aligned}
P_0 &= 2185103796349763249 \qquad (19 \text{ digits}),\\
P_1 &= (P_0^2+1)/2 \qquad (37 \text{ digits}),\\
P_2 &= (P_1^2+1)/2 \qquad (73 \text{ digits}),\\
P_3 &= (P_2^2+1)/2 \qquad (145 \text{ digits}),\\
P_4 &= (P_3^2+1)/2 \qquad (289 \text{ digits}),\\
P_5 &= (P_4^2+1)/2 \qquad (579 \text{ digits}),\\
P_6 &= (P_5^2+1)/2 \qquad (1155 \text{ digits}),\\
P_7 &= (P_6^2+1)/2 \qquad (2310 \text{ digits}).
\end{aligned}$$

The search program was designed to run on standard IBM PCs. We employed about 15 such machines, with clock speeds ranging from 200 MHz to 400 MHz. The

faster computers were sieving and testing numbers at rates of about ten billion per hour. We also found 174 additional chains of seven (probable) primes.

6. Primality Proofs

The first six numbers, P_0, P_1, ..., P_5, as well as other small primes mentioned in this section are easily verified by the UBASIC [3] program APRT-CLE, a straightforward implementation of the APRCL test. For $i = 6$ and 7 we attempt to factorize

$$P_i - 1 = (P_0 - 1) \prod_{j=0}^{i-1} \frac{1}{2} (P_j + 1) .$$

Thus

$$\begin{aligned}
P_0 - 1 &= 2^4 \cdot 233 \cdot 586132992583091, \\
(P_0 + 1)/2 &= 3^2 \cdot 5^3 \cdot 13 \cdot 761 \cdot 19087 \cdot 5143087, \\
(P_1 + 1)/2 &= 7^2 \cdot 1063 \cdot 189043 \cdot 7552723 \cdot 113558719 \cdot 141341652553, \\
(P_2 + 1)/2 &= 7058053 \cdot 584806347967357 6700713235221 \\
&\quad \cdot 345200415843690056348449077300192497 77, \\
(P_3 + 1)/2 &= 2179 \cdot 1847645923 \cdot C_{132}, \\
(P_4 + 1)/2 &= 307 \cdot 769 \cdot 262513 \cdot P_{278}, \\
(P_5 + 1)/2 &= 108139 \cdot 11360649709 \cdot 5586562264501 \cdot C_{550}, \\
(P_6 + 1)/2 &= 4177 \cdot 1372052449 \cdot 5098721569 \cdot 84098816095916212867 \cdot C_{1113},
\end{aligned}$$

where C_{132}, C_{550} and C_{1113} are composite numbers of 132, 550 and 1113 digits, respectively, and P_{278} is a 278-digit prime:

$$\begin{aligned}
P_{278} = {} & 66505518540598996114987486506055236521044267373138 \\
& 69473288000457727001877127498646545001634613677898 \\
& 53932112480508999228232340454335875401889420451888 \\
& 17780482079524485531037464472393979852934170207932 \\
& 02663155485302406204947222346461607409301255277393 \\
& 47884672922480556979611960 19.
\end{aligned}$$

The 28-digit factor of P_2+1 and the 20-digit factor of P_6+1 were found by Manfred Toplic and Paul Zimmermann.

Since we have a 41% partial factorization of P_6-1 we can establish the primality of P_6 by the methods of Brillhart, Lehmer and Selfridge [2]. (Similarly a 77% factorization of $P_5 - 1$ provides an alternative proof for P_5.)

It remains to deal with P_7. We do not have enough prime factors of $P_7 - 1$ for a simple proof, so we use a combination of methods. Suppose $d < P_7$ is a prime factor of P_7. The proof that no such d exists proceeds in several stages.

Gathering together the prime factors of P_7 listed above, let

$$\begin{aligned} F_1 \;=\;& 113640287731186786458633938802250351100681884906807428462580764453472121096964016986319204417628872057382836214336492569310719940321645143241641366672\\ & 3170462061367852058068428035299237332722989794734009917692032743575475918022578947700337216860293874\\ & 9656149846494398108697028994387332168146010883000001318014065142607708048404152552914010648779897057620296242032356309831230032409112281722441475141215123765209184430598589590008879997663256918503367\\ & 0725045143216049625264919180827687159384088708064291103468534974000 \text{ (517 digits).} \end{aligned}$$

Then, after confirming that the conditions of Pocklington's theorem [8] hold, we have

$$d \equiv 1 \pmod{F_1}. \tag{6.1}$$

Similarly, by Morrison's theorem [2, Theorem 16],

$$d \equiv \pm 1 \pmod{F_2}, \tag{6.2}$$

where $F_2 = 43^2 \cdot 73 = 134977$.

Next, we confirm that the conditions for the APRCL test (see, for example, Cohen and A. K. Lenstra [4] or Cohen and H. W. Lenstra [5]) are satisfied with the prime powers p^k: $\{2^5, 3^3, 5^2, 7, 11, 13\}$, and primes q: {11, 17, 19, 23, 29, 31, 37, 41, 53, 61, 67, 71, 79, 89, 97, 101, 109, 113, 127, 131, 151, 157, 181, 199, 211, 241, 271, 281, 313, 331, 337, 353, 379, 397, 401, 421, 433, 463, 521, 541, 547, 601, 617, 631, 661, 673, 701, 757, 859, 881, 911, 937, 991, 1009, 1051, 1093, 1171, 1201, 1249, 1301, 1321, 1801, 1873, 1951, 2003, 2017, 2081, 2161, 2311, 2341, 2377, 2521, 2731, 2801, 2861, 2971, 3121, 3169, 3301, 3361, 3433, 3511, 3697, 3851, 4159, 4201, 4621, 4951, 5281, 5851, 6007, 6301, 6553, 7151, 7393, 7561, 7723, 8009, 8191, 8317, 8581, 8737, 9241, 9829, 9901, 11551, 11701, 12601, 13729, 14561, 14851, 15121, 15401, 15601, 16381, 16633, 17551, 18481, 19801, 20021, 20593, 21601, 21841, 23761, 24571, 25741, 26209, 28081, 30241, 34651, 36037, 38611, 39313, 42901, 47521, 48049, 50051, 51481, 54601, 55441, 65521, 66529, 70201, 72073, 79201, 81901, 92401, 93601, 96097, 103951, 108109, 109201, 110881, 118801, 120121, 123553, 131041, 140401, 150151, 151201, 180181, 193051, 196561, 200201, 216217, 218401, 257401, 270271, 300301, 332641, 393121, 415801, 432433, 450451}. The result is that

$$d \equiv P_7^i \pmod{S} \text{ for some } i = 1, 2, \ldots, T-1, \tag{6.3}$$

where $T = 21621600$ is the product of the p^ks and $S = 8.164364 \cdot 10^{634}$, approximately, is the product of the qs.

Let $G = F_1 F_2 S$ and observe that F_1, F_2 and S are pairwise coprime. We combine (6.1), (6.2) and (6.3) by the Chinese Remainder Theorem to obtain

$$d \;\equiv\; \left(\frac{1}{F_2 S} \bmod F_1\right) F_2 S + \left(\frac{e}{F_1 S} \bmod F_2\right) F_1 S$$

$$+\left(\frac{P_7^i}{F_1F_2} \bmod S\right) F_1F_2 \pmod G$$

for some $e = \pm 1$ and $i = 1, 2, \ldots, T-1$. After eliminating all possible $d < \sqrt{P_7} < G$ by trial division we can conclude that P_7 is prime.

7. Acknowledgements

We would like to thank Jeremy Humphries, Manfred Toplic and Paul Zimmermann for contributing their own computer resources to the search for seven prime Pythagorean triangles. We are specifically grateful to Paul Zimmermann, who also made his Elliptic Curve program available to us for the partial factorization of $P_7 - 1$.

Abstract

The number of inversions in a random permutation is a way to measure the extent to which the permutation is "out of order". Let $I_n(k)$ denote the number of permutations of length n with k inversions. This paper gives asymptotic formulae for the sequences $\{I_{n+k}(n), n = 1, 2, \ldots\}$ for fixed k.

1. Introduction Let $a_1, a_2, \ldots, a_n$ be a permutation of the set $\{1, 2, \ldots, n\}$. If $i < j$ and $a_i > a_j$, the pair (a_i, a_j) is called an "inversion" of the permutation; for example, the permutation 3142 has three inversions: (3,1), (3,2), and (4,2). Each inversion is a pair of elements that is "out of sort", so the only permutation with no inversions is the sorted permutation.

2. Generating Function Let $I_n(k)$ represent the number of permutations of length n with k inversions.

Theorem 1 (Muir,1898). *[10] The numbers $I_n(k)$ have as generating function*

$$\Phi_n(x) = \sum_{k=0}^{\binom{n}{2}} I_n(k)x^k$$

$$= \prod_{j=1}^{n} \sum_{k=0}^{j\ \ 1} x^k$$
$$= \prod_{j=1}^{n} \frac{1-x^j}{1-x}.$$

Clearly the number of permutations with no inversions, $I_n(0)$, is 1 for all n, and in particular $I_1(0) = 1 = \Phi_1(x)$. So the formula given in the theorem is correct for $n = 1$. Consider a permutation of $n-1$ elements. We insert the nth element in the jth position, $j = 1, 2, \ldots, n$, choosing the insertion point randomly. Since the nth element is larger than the $n-1$ elements in the set $\{1, 2, \ldots, n-1\}$, by inserting the element in the jth position, $n-j$ additional inversions are added. The generating function for the number of additional inversions is $1 + x + x^2 + \cdots + x^{n\ \ 1}$ since each number of additional inversions is equally likely. The additional inversions are independent from the inversions present in the permutation of length $n-1$, so the total number of inversions has as its generating function the product of the generating function for $n-1$ inversions and the generating function for the additional inversions:

$$\Phi_n(x) \quad = \quad (1 + x + \cdots + x^{n\ \ 1})\Phi_{n\ \ 1}(x).$$

The required result then follows by induction.

Below is a table of values of the number of inversions (see sequence A008302 in [13], also [2], [3], [8], [11]):

Table 1 $I_n(k) = I_n(\binom{n}{2} - k)$

	k, number of inversions													
$n\backslash k$	0	1	2	3	4	5	6	7	8	9	10	11	12	13

3. Asymptotic Normality The unimodal behavior of the inversion numbers suggests that the number of inversions in a random permutation may be asymptotically normal. We explore this possibility by looking at the generating function for the probability distribution of the number of inversions. To get this generating function, we divide $\Phi_n(x)$ by $n!$ since each of the $n!$ permutations is equally likely.

$$\phi_n(x) \quad = \quad \Phi_n(x)/n!.$$

Following Vladimir Sachkov, we have the moment generating function [12]

$$\begin{aligned} M_n(x) &= \phi_n(e^x) \\ &= \prod_{j=1}^{n} \frac{1-e^{jx}}{j(1-e^x)} \\ &= \exp\left\{\frac{1}{2}\sum_{j=0}^{n}{}^{1} jx\right\} \prod_{j=1}^{n} \frac{e^{\ jx/2} - e^{jx/2}}{j(e^{\ x/2} - e^{x/2})} \\ &= \exp\left\{\frac{1}{2}\sum_{j=0}^{n}{}^{1} jx\right\} \prod_{j=1}^{n} \frac{e^{jx/2} - e^{\ jx/2}}{j(e^{x/2} - e^{\ x/2})} \\ &= \exp\left\{\frac{n(n-1)x}{4}\right\} \prod_{j=1}^{n} \frac{\sinh(xj/2)}{j\sinh(x/2)} \end{aligned}$$

An explicit formula for the generating function of the Bernoulli numbers is

$$\frac{x}{e^x - 1} \quad = \quad \sum_{k=0} B_k \frac{x^k}{k!}.$$

Hence

$$\begin{aligned} \frac{x}{e^x - 1} + \frac{x}{1 - e^{\ x}} &= \sum_{k=0} B_k \frac{x^k}{k!} + \sum_{k=0} B_k \frac{(-x)^k}{k!} \\ \frac{xe^{\ x/2}}{e^{x/2} - e^{\ x/2}} + \frac{xe^{x/2}}{e^{x/2} - e^{\ x/2}} &= 2\sum_{k=0} B_{2k} \frac{x^{2k}}{(2k)!} \end{aligned}$$

$$\begin{aligned}
\frac{e^{x/2}+e^{x/2}}{e^{x/2}-e^{x/2}} &= 2\sum_{k=0} B_{2k}\frac{x^{2k-1}}{(2k)!} \\
\frac{e^{x/2}+e^{x/2}}{2(e^{x/2}-e^{x/2})} &= \frac{1}{x}+\sum_{k=1} B_{2k}\frac{x^{2k-1}}{(2k)!} \\
\frac{e^{x/2}+e^{x/2}}{2(e^{x/2}-e^{x/2})}-\frac{1}{x} &= \sum_{k=1} B_{2k}\frac{x^{2k-1}}{(2k)!} \\
\ln\left(\frac{\sinh(x/2)}{x/2}\right) &= \sum_{k=1} B_{2k}\frac{x^{2k}}{2k(2k)!},
\end{aligned}$$

where the final step follows from integrating both sides and noting that

$$\lim_{x\to 0}\frac{\sinh(x/2)}{x/2}=1,$$

so the constant of integration is zero.

Using this generating function, we find that the log of the moment generating function is

$$\begin{aligned}
\ln M_n(x) &= \frac{n(n-1)x}{4}+\sum_{j=1}^{n}\left(\ln\left(\frac{\sinh(xj/2)}{xj/2}\right)-\ln\left(\frac{\sinh(x/2)}{x/2}\right)\right) \\
&= \frac{n(n-1)x}{4}+\sum_{k=1} B_{2k}\frac{x^{2k}}{2k(2k)!}\sum_{j=1}^{n}(j^{2k}-1).
\end{aligned}$$

Now consider $\ln M_n(t/\sigma)$, where σ is the standard deviation of the number of inversions in a random equiprobable permutation with n elements,

$$\sigma = \sqrt{\frac{2n^3+3n^2-5n}{72}},$$

$$\ln M_n(t/\sigma) = \frac{n(n-1)t}{4\sigma}+\sum_{k=1} B_{2k}\frac{t^{2k}}{2k(2k)!\sigma^{2k}}\sum_{j=1}^{n}(j^{2k}-1).$$

The sum

$$\sigma^{-2k}\sum_{j=1}^{n}(j^{2k}-1),$$

for $k>1$ is bounded above by the following integral:

$$\sum_{j=1}^{n}(j^{2k}-1)<\int_1^{n+1}(t^{2k}-1)dt=\frac{(n+1)^{2k+1}-1}{2k+1}-n,$$

so

$$\sigma^{-2k}\sum_{j=1}^{n}(j^{2k}-1)=O(n^{1-k}).$$

Hence

$$\sum_{k=2} B_{2k} \frac{t^{2k}}{2k(2k)!\sigma^{2k}} \sum_{j=1}^{n} (j^{2k} - 1) \to 0, \text{ as } n \to \infty ,$$

uniformly for t from any bounded set. Therefore

$$\begin{aligned} \lim_n M_n(t/\sigma) \exp\left\{ -\frac{n(n-1)t}{4\sigma} \right\} &= \lim_n \exp\left\{ \sum_{k=1} B_{2k} \frac{t^{2k}}{2k(2k)!\sigma^{2k}} \sum_{j=1}^{n} (j^{2k} - 1) \right\} \\ &= \lim_n \exp\left\{ B_2 \frac{t^2}{2(2)!\sigma^2} \sum_{j=1}^{n} (j^2 - 1) \right\} \\ &= e^{t^2/2}. \end{aligned}$$

This leads to the following theorem:

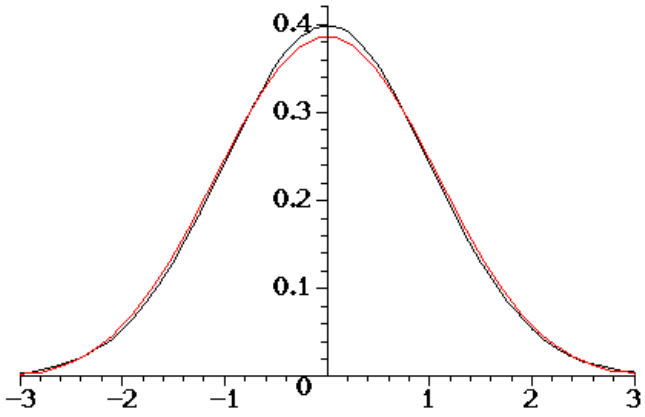
Theorem 2 (Sachkov). *[12] If ξ_n is a random variable representing the number of inversions in a random equiprobable permutation of n elements, then the random variable*

$$\eta_n = (\xi_n - E\xi_n)(\mathrm{Var}\xi_n)^{\ 1}$$

has as $n \to \infty$ an asymptotically normal distribution with parameters $(0, 1)$.

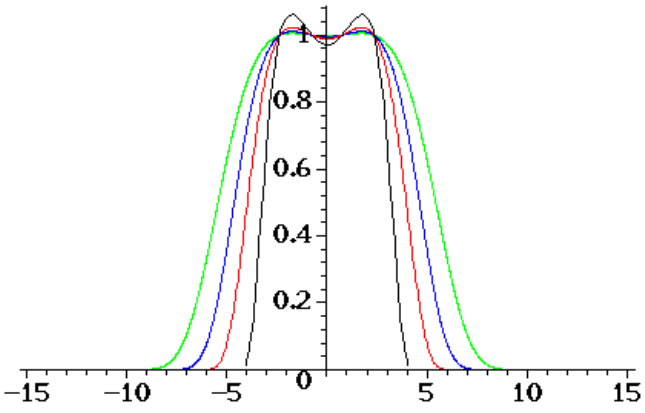
The graph below shows the density for a standard normal random variable in black. The red curve gives a continuous approximation for the discrete probability mass function for the number of inversions of a random permutation with n elements. The graph shown is for $n = 10$. As n increases, the red curve moves closer to the standard normal density so that it appears that the normal density may serve as a useful tool for approximating the inversion numbers.

Figure 1. Comparison of the inversion probability mass function to the standard normal density



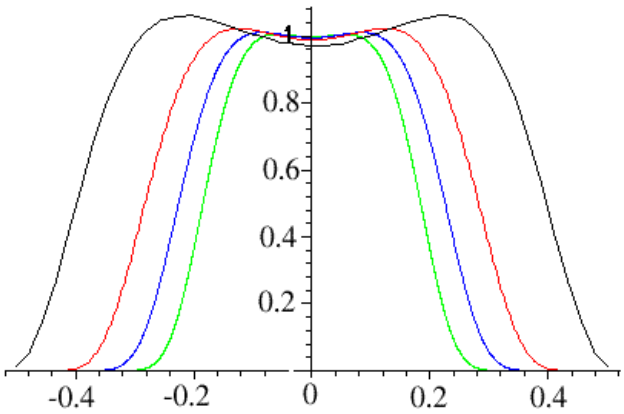
The figure below shows the ratio of the inversion numbers to the estimate provided by the normal density. The better the approximation, the closer the curve will be to 1. The graph is scaled so that the $x-$axis is the number of standard deviations from the mean.

Figure 2. The ratio of the inversion probability mass function to the standard normal density scaled by the number of standard deviations from the mean



The curves have roughly the shape of a cowboy hat. The top of the hat at about $y = 1$ seems to be getting broader as n increases (black is $n = 10$, red is $n = 25$, blue is $n = 50$, and green is $n = 100$), suggesting that the approximation improves with increasing n. Compare the figure above to the one below:

Figure 3. The ratio of the inversion probability mass function to the standard normal density scaled by the nonzero inversion numbers



The curves are rescaled in this figure so that 0 inversions is mapped to -0.5, and $\binom{n}{2}$ inversions is mapped to 0.5 on the $x-$axis. In this way, we can see whether the estimates for the nonzero inversion numbers improve as a percentage of the total nonzero inversion numbers as n increases. Note that the colored curves are in the opposite order of the preceding figure. The figure suggests that the estimates actually get worse as n increases. The width of the top of the cowboy hat is getting narrower as n increases. What this shows is that the relative error of the normal density approximation increases as n increases as we move further into the tails of the distribution. We can examine the asymptotic behavior of $I_n(k)$ for $k \leq n$ more closely.

4. An explicit formula for the inversion numbers Donald Knuth has made the observation that we may write an explicit formula for the kth coefficient of the generating function when $k \leq n$ ([8], p. 16). In that case,

Theorem 3 (Knuth, Netto). *[8],[11] The inversion numbers $I_n(k)$ satisfy the formula*

$$\begin{aligned} I_n(k) &= \binom{n+k-1}{k} + \sum_{j=1}(-1)^j \binom{n+k-u_j-j-1}{k-u_j-j} \\ &\quad + \sum_{j=1}(-1)^j \binom{n+k-u_j-1}{k-u_j}, \end{aligned} \tag{1}$$

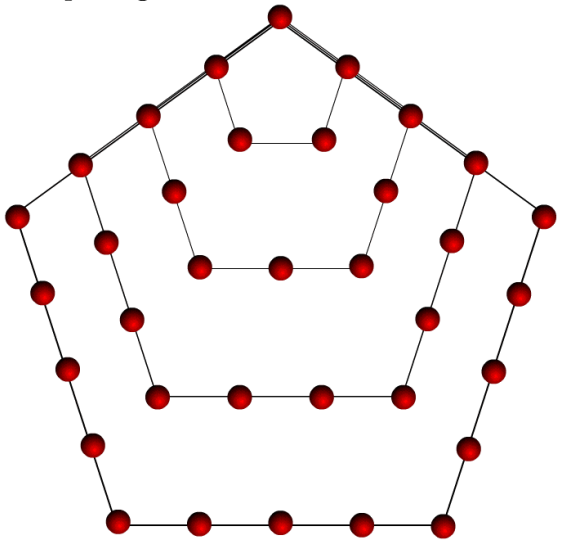
for $k \leq n$.

The binomial coefficients are defined to be zero when the lower index is negative, so there are only finitely many nonzero terms: $\lfloor -1/6 + \sqrt{1/36 + 2k/3} \rfloor$ in the first

sum, and $\lfloor 1/6 + \sqrt{1/36 + 2k/3} \rfloor$ in the second. The u_j are the pentagonal numbers (sequence A001318 in [13]),

$$u_j = \frac{j(3j-1)}{2}.$$

Figure 4. The pentagonal numbers



Donald Knuth's formula follows from the generating function and Euler's pentagonal number theorem.

Theorem 4 (Euler). *[1][7][8]*

$$\prod_{j=1}(1-x^j) = 1 + \sum_{k=1}(-1)^k (x^{k(3k \ \ 1)/2} + x^{k(3k+1)/2}).$$

Recall the generating function

$$\begin{aligned} \Phi_n(x) &= \prod_{j=1}^{n} \frac{1-x^j}{1-x} \\ &= \left(\prod_{j=1}^{n}(1-x^j)\right)(1-x)^{\ n} \\ &= \left(\prod_{j=1}^{n}(1-x^j)\right) \sum_{m=0} \binom{m+n-1}{m} x^m, \quad \text{for } |x|<1. \end{aligned}$$

The coefficients of $\prod_{j=1}^{n}(1-x^j)$ will match those in the power series expansion of the infinite product given by Euler's pentagonal number theorem up to the coefficient

on x^n. We consider the product

$$\left(\prod_{j=1}(1-x^j)\right)\sum_{m=0}\binom{m+n-1}{m}x^m = \left(1+\sum_{i=1}(-1)^i(x^{i(3i\ \ 1)/2}+x^{i(3i+1)/2})\right)\sum_{m=0}\binom{m+n-1}{m}x^m.$$

The coefficient on x^k is given by (1), for $k \leq n$.

5. An asymptotic formula for the inversion numbers We are interested in the sequences $\{I_{n+k}(n),\ n=1,2,\ldots\}$. For $k \geq 0$, the nth term of the sequence is given by

$$\begin{aligned} I_{n+k}(n) &= \binom{2n+k-1}{n} + \sum_{j=1}^{1/6+\sqrt{1/36+2n/3}}(-1)^j\binom{2n+k-u_j-j-1}{n-u_j-j} \\ &\quad + \sum_{j=1}^{1/6+\sqrt{1/36+2n/3}}(-1)^j\binom{2n+k-u_j-1}{n-u_j} \end{aligned} \tag{2}$$

With $a=u_j+j$ or $a=u_j$, all terms are of the form

$$\binom{2n+k-a-1}{n-a} = \frac{(2n+k-a-1)!}{(n-a)!(n+k-1)!}.$$

We can approximate this quantity using Stirling's approximation ([4], p.54 or [6], p.452):

$$n! = \sqrt{2\pi}n^{n+1/2}e^{\ \ n}(1+(12n)^{\ \ 1}+O(n^{\ \ 2})).$$

So we have

$$\begin{aligned} &\binom{2n+k-a-1}{n-a} \\ &\quad = \left(\frac{2n+k-a-1}{n-a}\right)^{n\ \ a}\left(\frac{2n+k-a-1}{n+k-1}\right)^{n+k\ \ 1}\left(\frac{2n+k-a-1}{2\pi(n+k-1)(n-a)}\right)^{1/2}\times \\ &\qquad \times\left(1-(8n)^{\ \ 1}+O(n^{\ \ 2})\right) \\ &\quad = \frac{2^{2n+k\ \ 1\ \ a}}{\sqrt{\pi n}}\left(1+\frac{(a+k-1)^2}{4(n-a)(n+k-1)}\right)^n\left(1-\frac{k+a-1}{2(n+k-1)}\right)^{k\ \ 1}\times \\ &\qquad \times\left(1-\frac{n+k-1}{2n+k-a-1)}\right)^a\left(\frac{1}{1-a/n}\left(\frac{k+a-1}{2(n+k-1)}\right)\right)^{1/2}\left(1-(8n)^{\ \ 1}+O(n^{\ \ 2})\right) \\ &\quad = \frac{2^{2n+k\ \ 1\ \ a}}{\sqrt{\pi n}}\left(1+\frac{n(a+k-1)^2}{4(n-a)(n+k-1)}\right)\left(1-\frac{(k-1)(k+a-1)}{2(n+k-1)}\right)\times \end{aligned}$$

$$\times\left(1-\frac{a(n+k-1)}{2n+k-a-1)}\right)\left(1+\frac{a-k+1}{4n}\right)\left(1-(8n)^{-1}+O(n^{-2})\right)$$
$$=\frac{2^{2n+k-1-a}}{\sqrt{\pi n}}\left(1-\frac{1}{8n}+\frac{1}{4n}(k+3a-(k+a)^2)+O(n^{-2})\right).$$

Using this asymptotic formula we can compute an asymptotic formula for the sum $I_{n+k}(n)$ given in equation (2):

$$I_{n+k}(n) = \frac{2^{2n+k-1}}{\sqrt{\pi n}}Q\left(1-\frac{C_1}{n}+\frac{C_2k-k^2}{4n}+O(n^{-2})\right)$$

where

$$\begin{aligned} Q &= \prod_{j=1}\left(1-\frac{1}{2^j}\right) \\ &= \sum_{i=1}(-1)^i\left(2^{-i(3i-1)/2}+2^{-i(3i+1)/2}\right) \\ &\approx 0.2887880951 \end{aligned}$$

is a digital search tree constant [5], and C_1 and C_2 are given by the convergent sums

$$\begin{aligned} C_1 &= \frac{1}{8}-\frac{1}{4Q}\sum_{i=1}(-1)^i\Big(2^{-i(3i-1)/2}(3(i(3i-1)/2)-(i(3i-1)/2)^2) \\ &\quad +2^{-i(3i+1)/2}(3(i(3i+1)/2)-(i(3i+1)/2)^2)\Big) \\ &\approx 1.855938894, \end{aligned}$$

and

$$\begin{aligned} C_2 &= 1+\frac{1}{Q}\sum_{i=1}(-1)^i(2^{-i(3i-1)/2}(i(3i-1))+2^{-i(3i+1)/2}(i(3i+1))) \\ &\approx 6.488067775, \end{aligned}$$

respectively. We summarize a less precise result in the following theorem:

Theorem 5.

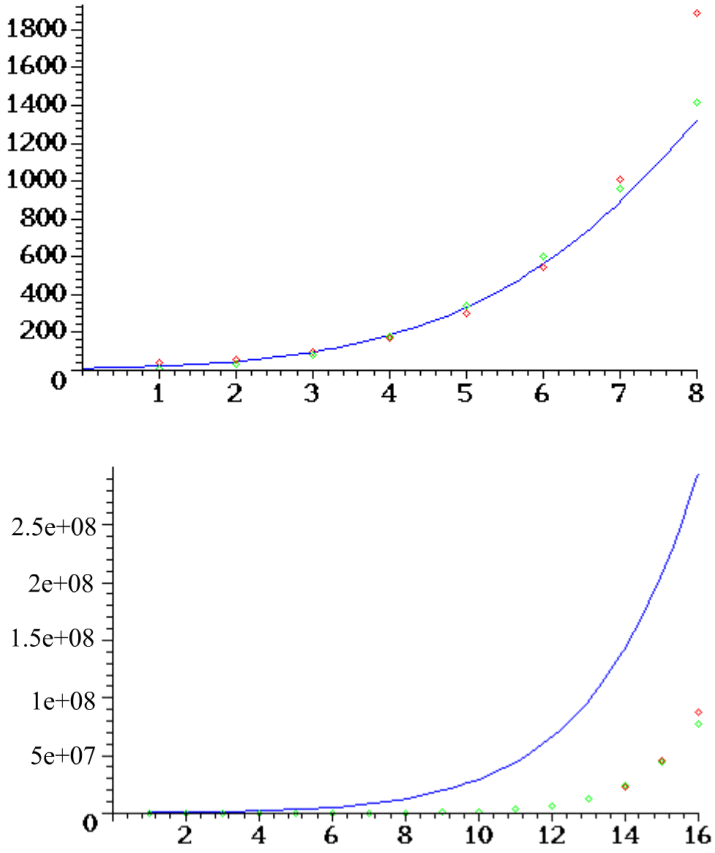
$$I_{n+k}(n) = \frac{2^{2n+k-1}}{\sqrt{\pi n}}Q\left(1+O(n^{-1})\right),\quad k\geq 0,$$

where $Q=\prod_{j=1}\left(1-\frac{1}{2^j}\right)$.

This formula provides asymptotic estimates for the sequences A000707, A001892, A001893, A001894, A005283, A005284 and A005285 of [13].

The figure below shows the behavior of the tail of the number of permutations with k inversions for $k \leq n$. The blue curve is $n!$ times normal density with mean $n(n-1)/4$ and variance $\frac{2n^3+3n^2 \quad 5n}{72}$, that is, the blue curve is the estimate of $I_n(k)$ based on the normal density. The red dots are the values of the asymptotic estimate; and the green dots are the exact values of $I_n(k)$. Where the red and green dots are not both visible, one dot covers the other. The figure shows the tail for $n = 8$ and $n = 16$.

Figure 4. Comparison of normal density estimate to asymptotic formula and actual inversion numbers



From our asymptotic formula for $I_n(n)$ we can see that

$$\lim_n \frac{I_n(n)}{I_n \ _1(n-1)} = 4,$$

but the normal density approximation for the ratio $\frac{I_n(n)}{I_{n-1}(n \ 1)}$ gives the estimate $ne^{\ 9/8}$ as n tends to infinity. Hence the normal density approximation grows much faster than the inversion numbers in the tails do.

Integral Representations of Catalan and Related Numbers

K.A.Penson
J.-M. Sixdeniers

Université Pierre et Marie Curie
Laboratoire de Physique Théorique des Liquides

Abstract

We derive integral representations for the Catalan numbers $C(n)$, shifted Catalan numbers $C(n+p)$, and the numbers $n!\cdot C(n)$ and $C(n)\cdot B(n)$, where $B(n)$ are the Bell numbers, for $n=0,1\ldots$. Our method is to use inverse Mellin transform. All these numbers are power moments of positive functions, and their representations turn out to be unique.

The Catalan numbers $C(n)$, $n=0,1,2,\ldots$, defined by

$$C(n)=\frac{\binom{2n}{n}}{n+1} \qquad , \tag{1}$$

are among the most ubiquitous sequences in enumerative combinatorics. Stanley [13] cites no less than 66 different combinatorial settings where these numbers appear. The first few Catalan numbers are

$$1,1,2,5,14,42,132,429,1430,4862$$

for $n=0\ldots 9$. A plethora of information about the $C(n)$'s can be found in [11], under sequence no. A000108.

In this note we derive an integral representation of $C(n)$ as the n-th power moment of a certain non-negative function $W_C(x)$ on the positive half-axis. We also study the ramifications of this representation for other integer sequences involving $C(n)$.

To this end we seek a function $W_C(x)$ such that

$$\int_0^\infty x^n W_C(x)dx \quad = \quad C(n) \tag{2}$$

$$= \frac{4^n \Gamma(n+1/2)}{\sqrt{\pi}\Gamma(n+2)} \quad , \qquad n = 0, 1, \ldots \quad . \tag{3}$$

Replacing n by a complex variable $s-1$, we rewrite Eq.(3) as

$$\int_0^\infty x^{s-1} W_C(x) dx = \frac{4^{s-1}\Gamma(s-1/2)}{\sqrt{\pi}\Gamma(s+1)} \quad , \quad \text{Re } s > 1 \quad , \tag{4}$$

which implies that

$$W_C(x) = \mathcal{M}^{-1}\left[\frac{4^{s-1}\Gamma(s-1/2)}{\sqrt{\pi}\Gamma(s+1)}; x\right], \tag{5}$$

where $\mathcal{M}^{-1}[f^*(s); x] = f(x)$ is the inverse Mellin transform [12], with $f^*(s) = \mathcal{M}[f(x); s] = \int_0^\infty x^{s-1} f(x) dx$ the Mellin transform of $f(x)$. We note the following property of $\mathcal{M}$ [12] :

$$\mathcal{M}\left[x^b f(ax^h); s\right] = \frac{1}{h} a^{-\frac{s+b}{h}} f^*\left(\frac{s+b}{h}\right), \qquad b \in R, \quad h > 0, \tag{6}$$

which, when specialized to $a = \frac{1}{4}$, $b = -\frac{1}{2}$ and $h = 1$, implies that

$$\mathcal{M}\left[x^{-\frac{1}{2}} f\left(\frac{x}{4}\right); s\right] = 4^s f^*(s-1/2)/2 \quad . \tag{7}$$

Adopting the standard notation $(y)_+^\alpha = y^\alpha$ if $y > 0$, $(y)_+^\alpha = 0$ otherwise, and using the formula 2.2(1), p.151 of [5] :

$$\mathcal{M}\left[(1-x)_+^{\alpha-1}; s\right] = \Gamma(\alpha)\frac{\Gamma(s)}{\Gamma(\alpha+s)} \quad , \qquad \alpha > 0, \quad s > 0, \tag{8}$$

we can apply Eq.(7) with $f(x) = (1-x)_+^{\alpha-1}$ and $\alpha = \frac{3}{2}$. This yields

$$W_C(x) = \frac{x^{-\frac{1}{2}}}{\pi}\left(1 - \frac{x}{4}\right)_+^{\frac{1}{2}}. \tag{9}$$

The function $W_C(x)$ is displayed on Fig.(1). The desired integral representation of $C(n)$ is then

$$C(n) = \int_0^4 x^n \left(\frac{\sqrt{\frac{4-x}{x}}}{2\pi}\right) dx \quad . \tag{10}$$

This is the solution of the Hausdorff moment problem on $[0, 4]$, which is always unique [1], and so the representation of Eq.(10) is also unique.

By the same token we can find the solution of

$$\int_0^\infty x^n W_{C,p}(x) dx = C(n+p), \qquad n = 0, 1, 2 \ldots, \qquad p = 1, 2, \ldots, \tag{11}$$

i.e. the unique representation of the shifted Catalan numbers $C(n+p)$, as the Hausdorff moments of

$$W_{C,p}(x) = \frac{x^{p-\frac{1}{2}}}{\pi}\left(1 - \frac{x}{4}\right)_+^{\frac{1}{2}}. \tag{12}$$

The Mellin convolution property for products of Mellin transforms, in its simplest incarnation, states ([12], [5]) that if $\mathcal{M}[W_{1,2}(x); s] = \rho_{1,2}(s)$ then

$$\mathcal{M}^{-1}[\rho_1(s)\rho_2(s); x] = W_{12}(x) \equiv \int_0^\infty \frac{1}{t} W_1\left(\frac{x}{t}\right) W_2(t) dt \quad . \tag{13}$$

Observe that $W_{1,2}(x) > 0$ implies $W_{12}(x) > 0$.

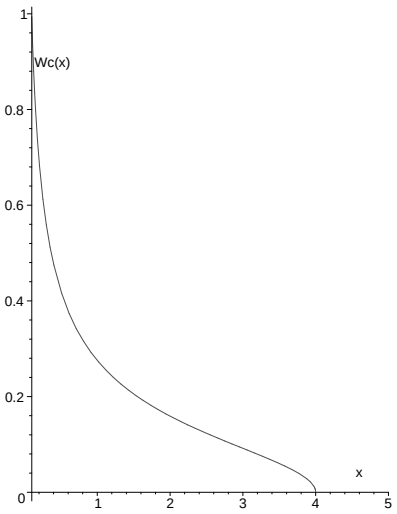

Figure 1: : The function $W_C(x)$, s. Eq.(9). This function diverges at $x = 0$.

As an application of Eq.(13) we look for an integral representation of the sequence $n! \cdot C(n)$ whose initial terms are $1, 1, 4, 30, 336, 5040, 95040, 2162160, 57657600, 1764322560$, for $n = 0 \ldots 9$; compare [11], no. A001761. Using Eq.(9) and performing the Mellin convolution in Eq.(13) with $W_1(x) = e^{-x}$ and $W_2(x) = W_C(x)$, one ends up with the following Stieltjes moment problem :

$$\int_0^\infty x^n W_{1C}(x) dx = n! \cdot C(n) = \frac{(2n)!}{(n+1)!} \quad , \quad n = 0, 1, \ldots , \tag{14}$$

with the solution

$$W_{1C}(x) = \frac{1}{2\pi\sqrt{x}} \int_{\frac{x}{4}}^\infty e^{-t} \frac{\sqrt{4t-x}}{t} dt \tag{15}$$

$$= -\frac{1}{2} + \frac{1}{\sqrt{\pi x}} e^{-\frac{x}{4}} + \frac{1}{2} \mathrm{erf}\left(\frac{\sqrt{x}}{2}\right) \quad , \tag{16}$$

where $\mathrm{erf}(y)$ is the error function. The function $W_{1C}(x)$ is shown in Fig.(2). As $W_{1C}(x) > 0$, the (sufficient) Carleman condition ($\sum_{n=1}^\infty (\frac{(2n)!}{(n+1)!})^{-\frac{1}{2n}} = \infty$) (cf. Ref.[1]) indicates that the solution $W_{1C}(x)$ of Eq.(16) is also unique. Similar results are obtained by using $W_{C,p}(x)$ instead of $W_C(x)$ in Eq.(13).

Another use of Eq.(13) is illustrated by considering the sequence $C(n) \cdot B(n)$, where $B(n)$ are the Bell numbers (see [11], no. A000110, and [2]). The initial terms of this sequence are 1, 1, 4, 25, 210, 2184, 26796, 376233, 5920200, 102816714, for $n = 0 \ldots 9$. For this last sequence see [11], no. A064299. The weight function whose n-th moment is equal to $B(n)$ is

$$W_B(x) = \frac{1}{e} \sum_{k=1}^\infty \frac{\delta(x-k)}{k!} \quad , \tag{17}$$

which is a consequence of Dobiński formula, $B(n) = \frac{1}{e} \sum_{k=1}^\infty \frac{k^n}{k!}$, see [2]. In Eq.(17), $\delta(y)$ is Dirac's delta function. By Mellin convolution of $W_B(x)$ with $W_C(x)$ one obtains

$$W_{BC}(x) = \frac{1}{2\pi e} \sum_{k=1}^\infty \frac{1}{k k!} \sqrt{\frac{4k-x}{x}} H\left(4 - \frac{x}{k}\right) \quad , \tag{18}$$

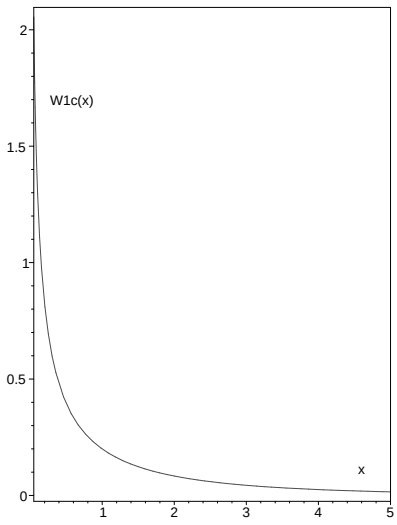

Figure 2: : The function $W_{1C}(x)$, s. Eq.(16). This function diverges at $x = 0$.

which, via Carleman's criterion, is the only positive function such that its n-th moment is equal to $C(n)\cdot B(n)$. In Eq.(18) $H(y)$ is the Heaviside function. The function $W_{BC}(x)$ is displayed on Fig.(3).

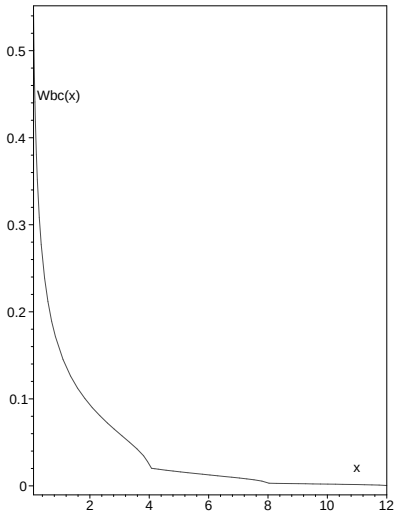

Figure 3: : The function $W_{BC}(x)$, s. Eq.(18). This function diverges at $x = 0$.

The last sequence that will concern us here is $(n!)^2 C(n) = \frac{(2n)!}{n+1}$. Its initial terms are

$$1, 1, 8, 180, 8064, 604800, 68428800, 10897286400, 2324754432000$$

for $n = 0 \ldots 9$; compare [11], no. A060593. Proceeding as in Eqs.(3) and (4), we are looking for $W_3(x)$ satisfying

$$\int_0^\infty x^{s-1} W_3(x) dx = \frac{4^{s-1}\Gamma(s-1/2)\Gamma^2(s)}{\sqrt{\pi}\Gamma(s+1)} \qquad , \quad \text{Re } s > 1 \quad . \tag{19}$$

It appears that when studying Eq.(19) it is possible to avoid using $W_C(x)$. As the first step we observe from

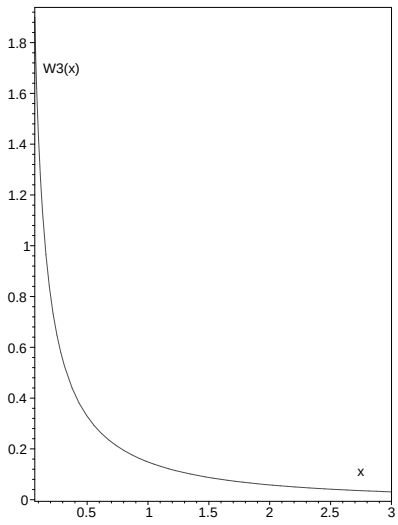

Figure 4: : The function $W_3(x)$, s. Eq.(24). This function diverges at $x = 0$.

Eq.(6) that

$$\mathcal{M}^{-1}\left[\Gamma\left(s-\frac{1}{2}\right);x\right] = \frac{e^{-x}}{\sqrt{x}} \qquad . \tag{20}$$

In addition, the following relation holds :

$$\mathcal{M}^{-1}\left[\frac{\Gamma^2(s)}{\Gamma(s+1)};x\right] = -Ei(-x) \qquad , \tag{21}$$

which is the formula 8.1(1), p.182 of [5]. In Eq.(21) $Ei(y)$ is the exponential integral function. Combining Eqs.(20) and (21) in the Mellin convolution we obtain

$$\mathcal{M}^{-1}\left[\frac{\Gamma(s-1/2)\Gamma^2(s)}{\Gamma(s+1)};x\right] = -\frac{1}{\sqrt{x}}\int_0^\infty t^{-\frac{1}{2}} t^{-\frac{x}{t}} Ei(-t)dt \tag{22}$$

$$= 2\sqrt{\frac{\pi}{x}}e^{-2\sqrt{x}} + 4\sqrt{\pi}Ei(-2\sqrt{x}) \qquad , \quad x>0 \quad . \tag{23}$$

In writing Eq.(23) we have used the formula 2.5.4.2, p.72 of [6]. Finally, we use Eq.(6) again (with $a = \frac{1}{4}$, $b = 0$ and $h = 1$) and from Eq.(19) we get the solution

$$W_3(x) = \frac{1}{\sqrt{x}}e^{-\sqrt{x}} + Ei(-\sqrt{x}) \qquad , \tag{24}$$

which is plotted in Fig.(4). As $W_3(x) > 0$, by Carleman's criterion the solution is again unique.

Remark: E. P.Wigner [14] has demonstrated that Eq.(10), under a suitable parametrization, describes the distribution function of eigenvalues of an ensemble of random, symmetric, real matrices.

Integral representations of other combinatorial numbers can be found in [3]. For further applications of Mellin convolution formula Eq.(13), one may consult [5], [10], [7], [8] , [4] and [9].

A Million New Amicable Pairs

Mariano Garcia
Department of Mathematics
Touro College
27 West 23rd Street, New York, NY 10010

Abstract

The author has recently discovered over one million new amicable pairs, bringing to more than two million the total of known amicable numbers and strengthening the validity of the as yet unproved conjecture that there are infinitely many such pairs.

Two distinct natural numbers M and N are said to be *amicable* if each is equal to the sum of the aliquot parts of the other. This is equivalent to saying that M and N are amicable if $\sigma(M) = \sigma(N) = M + N$, where $\sigma(M)$ stands for the sum of all the positive divisors of M.

The smallest example of an amicable pair is $(220 = 2^2 \cdot 5 \cdot 11,\ 284 = 2^2 \cdot 71)$, which was known to the Pythagoreans. For several centuries this was the only known amicable pair. Around the year 1300, the amicable pair $(2^4 \cdot 23 \cdot 47,\ 2^4 \cdot 1151)$ was discovered by al-Banna and around 1600, Yazdi discovered the pair $(2^7 \cdot\ 191 \cdot\ 383,\ 2^7 \cdot 73727)$. The second pair above was later rediscovered by Fermat in 1636 and the third pair by Descartes in 1638. The previously listed three pairs were the only known amicable pairs until Euler [2] discovered 59 additional ones in the middle of the eighteenth century. Since then, several mathematicians have discovered amicable numbers, including Legendre, Poulet, Gerardin, Seedhoff, Mason, Escott and others.

Until the year 1972, in order to find out what the existing known amicable pairs were, one had to search through the various individual papers on the subject. But in that year, Lee and Madachy published [4] in the Journal of Recreational Mathematics an article entitled "The History and Discovery of Amicable Numbers," which dealt with the history of the subject and listed the 1108 known amicable pairs at that time.

In 1986 Herman te Riele determined and published [5] all the amicable pairs below 10^{10} and, together with Borho, Battiato, Hoffmann and Lee, published [7] a list of known amicable pairs between 10^{10} and 10^{52}. From 1986 to 1995, te Riele became the official "collector" of amicable pairs. People who discovered amicable pairs sent them to him for verification that the pairs were new and, if so, they were added to the collection. Te Riele also made up several supplementary lists that he sent to interested people.

In 1995, Pedersen started collecting amicable numbers in the Internet. Today all known amicable pairs can be seen by examining the web pages entitled *Known amicable pairs* [9].

As of January 15, 2001, a total of 843,783 amicable pairs were known. Using essentially the BDE method indicated in [8], and based on ideas contained in [1], [3], and [6], the author has found over one million new amicable pairs during the first three months of the year 2001. In the following paragraphs we give a brief outline of the method used:

Suppose E and N are natural numbers with E relatively prime to N and to $\sigma(N)-1$, and satisfying the condition

$$\sigma(E)\cdot\sigma(N)=E\cdot(N+\sigma(N)-1). \tag{1}$$

If now p,q and r are primes such that $E\cdot p\cdot q$ and $E\cdot N\cdot r$ constitute an amicable pair, we must have $r=(p+1)\cdot(q+1)/\sigma(N)-1$. Also,

$$\sigma(E)\cdot(p+1)\cdot(q+1)=E\cdot[p\cdot q+N\cdot r]=E\cdot[p\cdot q+N\cdot(p+1)\cdot(q+1)/\sigma(N)-N]$$

and thus

$$\sigma(E)\cdot\sigma(N)\cdot(p+1)\cdot(q+1)=E\cdot[\sigma(N)\cdot p\cdot q+N\cdot(p+1)\cdot(q+1)-N\cdot\sigma(N)]. \tag{2}$$

Dividing (2) by (1), we obtain

$$(p+1)\cdot(q+1)=[\sigma(N)\cdot p\cdot q+N\cdot(p+1)\cdot(q+1)-N\cdot\sigma(N)]/[N+\sigma(N)-1].$$

Multiplying through by $N+\sigma(N)-1$ and simplifying, we get

$$[\sigma(N)-1]\cdot(p+1)\cdot(q+1)=\sigma(N)\cdot p\cdot q-N\cdot\sigma(N)$$

or

$$\sigma(N)-1+N\cdot\sigma(N)=p\cdot q-[\sigma(N)-1]\cdot p-[\sigma(N)-1]\cdot q.$$

Adding $[\sigma(N)-1]^2$ to both sides and simplifying, we obtain

$$\sigma(N)\cdot[N+\sigma(N)-1]=[p-\sigma(N)+1]\cdot[q-\sigma(N)+1]. \tag{3}$$

This condition is necessary and sufficient for $E\cdot p\cdot q$ and $E\cdot N\cdot r$ to be amicable.

To find the amicable pairs generated in this manner, all we need to do is obtain all the possible factorizations into pairs of the left-hand side of (3), and for each such factorization $A\cdot B$, set $p-\sigma(N)+1=A$ and $q-\sigma(N)+1=B$ and solve for p and q. When $p,\ q$ and $r=(p+1)\cdot(q+1)/\sigma(N)-1$ are all prime, we obtain an amicable pair. We give two examples:

Example 1. $2^4\cdot23\cdot47$ and $2^4\cdot1151$ are amicable and satisfy equation (1). Then equation (3) becomes

$$2^{10}\cdot3^4\cdot31=(p-1151)\cdot(q-1151).$$

Trying out the various possible factorizations into pairs of the left-hand side, and checking that $p,\ q$ and $r=(p+1)\cdot(q+1)/1152-1$ are prime, we get the two solutions

$$(p=1399,\ q=11519,\ r=13999)$$

and

$$(p=1583,\ q=7103,\ r=9767).$$

Here the given amicable pair generates two amicable pairs. These are

$$(2^4\cdot23\cdot47\cdot13999,\ 2^4\cdot1399\cdot11519)$$

and

$$(2^4\cdot23\cdot47\cdot9767,\ 2^4\cdot1583\cdot7103).$$

Example 2. $2^4\cdot19\cdot79$ and $2^4\cdot1599$ are not amicable, but satisfy condition (1). Then equation (3) becomes

$$2^8\cdot5^4\cdot31=(p-1599)\cdot(q-1599).$$

Trying out the various possible factorizations into pairs of the left-hand side, and checking that $p,\ q$ and $r=(p+1)\cdot(q+1)/1600-1$ are prime, we get the single solution $(p=2591,\ q=6599,\ r=10691)$. Here the given non-amicable pair generates one amicable pair. This is $(2^4\cdot19\cdot79\cdot10691,\ 2^4\cdot2591\cdot6599)$.

The selection of a suitable common factor E was useful in obtaining our million amicable pairs. The equation $\sigma(E)/E=$ a fraction a/b, has no solution for most fractions, but solutions do exist. In the case of an amicable pair, $\sigma(E)/E$ must be a fraction between 1 and 2. When a solution exists, it is usually the only solution. However, sometimes two or more solutions exist for the equation. There is one case which gives seven solutions, namely $\sigma(E)/E=1024/513$. Here the solutions are $E=$

(1) $3^3\cdot5^2\cdot19\cdot31$
(2) $3^4\cdot7\cdot11^2\cdot19^2\cdot127$
(3) $3^4\cdot7\cdot11^2\cdot19^4\cdot151\cdot911$
(4) $3^5\cdot7^2\cdot13\cdot19^2\cdot127$
(5) $3^5\cdot7^2\cdot13\cdot19^4\cdot151\cdot911$
(6) $3^6\cdot5\cdot19\cdot23\cdot137\cdot547\cdot1093$

$$(7) \quad 3^{10} \cdot 5 \cdot 19 \cdot 23 \cdot 107 \cdot 3851$$

The author made full use of this particular set, choosing as a common factor one of these, often multiplied by a suitable factor. Each new amicable pair obtained yielded seven amicable pairs in most cases (on occasions only six because of conflicts that may arise with the factors). There was one particular combination of E and N that produced $7 \times 35279 = 246953$ new amicable pairs. This was the case where

$$E = 3^3 \cdot 5^2 \cdot 19 \cdot 31 \cdot 757 \cdot 3329 \text{ and } N = 1511 \cdot 72350721629 \cdot 2077116867246979.$$

As an illustration, one of the solutions obtained is $(E \cdot N \cdot r,\ E \cdot p \cdot q)$ with E and N as indicated and
$p = 22722472723380793192451424303 7$,
$q = 11064807687934848827494555213217266088154287 99$,
$r = 11064807687934853370486290815437003410651550 37$. When multipled out, each member of this amicable pair has 87 digits. The reader may view this and other examples by examining Pedersen's list of known amicable pairs [9].

The author's findings bring to more than two million the total number of known amicable pairs and strengthen the validity of the as yet unproved conjecture that there are infinitely many amicable pairs.

Milton Keynes MK7 6AA, UK

Abstract: Improved upper and lower bounds on the number of square-free ternary words are obtained. The upper bound is based on the enumeration of square-free ternary words up to length 110. The lower bound is derived by constructing generalised Brinkhuis triples. The problem of finding such triples can essentially be reduced to a combinatorial problem, which can efficiently be treated by computer. In particular, it is shown that the number of square-free ternary words of length n grows at least as 65^{n/40}, replacing the previous best lower bound of 2^{n/17}.

IMPROVED BOUNDS ON THE NUMBER OF TERNARY SQUARE-FREE WORDS

UWE GRIMM

Abstract. Improved upper and lower bounds on the number of square-free ternary words are obtained. The upper bound is based on the enumeration of square-free ternary words up to length 110. The lower bound is derived by constructing generalised Brinkhuis triples. The problem of finding such triples can essentially be reduced to a combinatorial problem, which can efficiently be treated by computer. In particular, it is shown that the number of square-free ternary words of length n grows at least as $65^{n/40}$, replacing the previous best lower bound of $2^{n/17}$.

1. Introduction

A word w is a string of letters from a certain alphabet Σ, the number of letters of w is called the length of the word. The set of words of length n is $\mathcal{L}(n) = \Sigma^n$, and the union

$$\mathcal{L} = \bigcup_{n\geq 0} \mathcal{L}(n) = \Sigma^{\mathbb{N}_0} \tag{1}$$

is called the language of words in the alphabet Σ. This is a monoid with concatenation of words as operation and the empty word λ, which has zero length, as neutral element [12]. For a word w, we denote by $\bar{w}$ the corresponding reversed word, i.e., the word obtained by reading w from back to front. A palindrome is a word w that is symmetric, $w = \bar{w}$.

Square-free words [1–13] are words w that do not contain a "square" yy of a word y as a subword (factor). In other words, w can only be written in the form $xyyz$, with words x, y and z, if $y = \lambda$ is the empty word. In a two-letter alphabet $\{0, 1\}$, the complete list of square-free words is $\{\lambda, 0, 1, 01, 10, 010, 101\}$. However, in a three-letter alphabet $\Sigma = \{0, 1, 2\}$, square-free words of arbitrary length exist, and the number of square-free words of a given length n grows exponentially with n [4, 3, 7].

We denote the set of square-free words of length n in the alphabet $\Sigma = \{0, 1, 2\}$ by $\mathcal{A}(n) \subset \mathcal{L}(n)$. The language of ternary square-free words is

$$\mathcal{A} = \bigcup_{n\geq 0} \mathcal{A}(n) \subset \Sigma^{\mathbb{N}_0}. \tag{2}$$

We are interested in the number of square-free words of length n

$$a(n) = |\mathcal{A}(n)| \tag{3}$$

and in estimating the growth of $a(n)$ with the length n. For $n = 0, 1, 2, 3$, the sets of ternary square-free words are

$$\begin{aligned}
\mathcal{A}(0) &= \{\lambda\},\\
\mathcal{A}(1) &= \{0, 1, 2\},\\
\mathcal{A}(2) &= \{01, 02, 10, 12, 20, 21\},\\
\mathcal{A}(3) &= \{010, 012, 020, 021, 101, 102, 120, 121, 201, 202, 210, 212\},
\end{aligned} \tag{4}$$

where λ denotes the empty word. Hence $a(0) = 1$, $a(1) = 3$, $a(2) = 6$, $a(3) = 12$, and so on, see [1] where the values of $a(n)$ for $n \leq 90$ are tabulated. In [16], the sequence is listed as A006156.

2. Upper bounds obtained by enumeration

Obviously, a word w of length $m+n$, obtained by concatenation of words w_1 of length m and w_2 of length n, can only be square-free if w_1 and w_2 are square-free. This necessary, but not sufficient, condition implies the inequality

$$a(m+n) \leq a(m)a(n) \tag{5}$$

for all $m, n \geq 0$. By standard arguments, see also [1], this guarantees the existence of the limit

$$s := \lim_{n\to\infty} a(n)^{\frac{1}{n}}, \tag{6}$$

the growth rate or "connective constant" of ternary square-free words [9]. The precise value of s is not known, but lower [4, 3, 7] and upper bounds [1] have been established. It is the purpose of this paper to improve both the lower and the upper bounds.

It is relatively easy to derive reasonable upper bounds from the inequality (5). In fact [1], one can slightly improve on (5) by considering two words w_1 and w_2 of length $m \geq 2$ and $n \geq 2$, such that the last two letters of w_1 are equal to the first two letters of w_2, and we join them to a word w of length $m+n-2$ by having the two words overlap on these two letters. This yields

$$a(m+n-2) \leq \frac{1}{6}a(m)a(n), \tag{7}$$

for all $m, n \geq 2$, because there are precisely $a(n)/6$ square-free letters of length $n \geq 2$ that start with the last two letters of w_1. Taking n fixed, one obtains

$$s^{n-2} = \lim_{m\to\infty} \frac{a(m+n-2)}{a(m)} \leq \frac{a(n)}{6} \tag{8}$$

and hence the upper bound

$$s \leq \left(\frac{a(n)}{6}\right)^{\frac{1}{n-2}} \tag{9}$$

for any $n \geq 3$. This bound can be systematically improved by calculating $a(n)$ for as large values of n as possible. The bound given in [1], from $a(90) = 258\,615\,015\,792$, is

$$s \leq 43\,102\,502\,632^{\frac{1}{88}} = 1.320\,829\,\ldots \tag{10}$$

The results given in table 1 extend the previously known values of $a(n)$ [1] to lengths $n \leq 110$. They were obtained by a simple algorithm, extending square-free words letter by letter and checking that the new letter does not lead to the formation of any square. The value $a(110)$ yields an improved upper bound of

$$s \leq 8\,416\,550\,317\,984^{\frac{1}{108}} = 1.317\,277\,\ldots \tag{11}$$

3. Brinkhuis triples and lower bounds

While the upper bound is already relatively close to the actual value of s, which was estimated in reference [1] to be about 1.301 76 on the basis of the first 90 values, it is much more difficult to obtain any reasonable lower bound for s. In order to derive a lower bound, one has to show that $a(n)$ grows exponentially in n with optimal growth bound. This can be achieved by demonstrating that each square-free word of length n gives rise to sufficiently many different square-free words of some length $m > n$. This was first done by Brinkhuis [4], by constructing what is now known as a Brinkhuis triple or a Brinkhuis triple pair.

TABLE 1. The number of ternary square-free words $a(n)$ of length n for $91 \le n \le 110$.

n	$a(n)$	n	$a(n)$
91	336 655 224 582	101	4 704 369 434 772
92	438 245 025 942	102	6 123 969 129 810
93	570 491 023 872	103	7 971 950 000 520
94	742 643 501 460	104	10 377 579 748 374
95	966 745 068 408	105	13 509 138 183 162
96	1 258 471 821 174	106	17 585 681 474 148
97	1 638 231 187 596	107	22 892 370 891 330
98	2 132 586 986 466	108	29 800 413 809 730
99	2 776 120 525 176	109	38 793 041 799 498
100	3 613 847 436 684	110	50 499 301 907 904

Definition 1. An n-Brinkhuis triple pair is a set $\mathcal{B} = \{\mathcal{B}^{(0)}, \mathcal{B}^{(1)}, \mathcal{B}^{(2)}\}$ of three pairs $\mathcal{B}^{(i)} = \{U^{(i)}, V^{(i)}\} \subset \mathcal{A}(n)$, $i \in \{0,1,2\}$, of pairwise different square-free words such that the set of 96 words of length $3n$

$$\bigcup_{w_1w_2w_3 \in \mathcal{A}(3)} \Big\{ W_1W_2W_3 \mid W_j \in \mathcal{B}^{(w_j)}, j = 1,2,3 \Big\} \subset \mathcal{A}(3n).$$

In other words, it is required that all $3n$-letter images of the twelve elements of $\mathcal{A}(3)$ under any combination of the eight maps

$$\varrho_{x,y,z} : \begin{cases} 0 \to x \in \mathcal{B}^{(0)} \\ 1 \to y \in \mathcal{B}^{(1)} \\ 2 \to z \in \mathcal{B}^{(2)} \end{cases} \tag{12}$$

are square-free. This property is sufficient to ensure that images of any square-free word in the alphabet Σ under any combination of the eight maps to each of its letters is again square-free. This can be shown as follows.

Consider the six-letter alphabet $\tilde{\Sigma} = \{0, 0', 1, 1', 2, 2'\}$ and a language $\tilde{\mathcal{A}}$ consisting of all words of $\mathcal{A}$ with an arbitrary number of letters replaced by their primed companions. In other words,

$$\tilde{\mathcal{A}} = \bigcup_{n \ge 0} \tilde{\mathcal{A}}(n), \qquad \tilde{\mathcal{A}}(n) = \Big\{ w \in \tilde{\Sigma}^n \mid \pi(w) \in \mathcal{A}(n) \Big\} \tag{13}$$

where π is the map

$$\pi : \tilde{\Sigma} \to \Sigma, \quad \pi(0) = \pi(0') = 0,\ \pi(1) = \pi(1') = 1,\ \pi(2) = \pi(2') = 2, \tag{14}$$

that projects back to the three-letter alphabet Σ. The map

$$\varrho : \begin{cases} 0 \to U^{(0)},\ 0' \to V^{(0)} \\ 1 \to U^{(1)},\ 1' \to V^{(1)} \\ 2 \to U^{(2)},\ 2' \to V^{(2)} \end{cases} \tag{15}$$

is a uniformly growing morphism from the language $\tilde{\mathcal{A}}$ into the language $\mathcal{L}$. By the condition (1), this morphism is square-free on all three-letter words in $\tilde{\mathcal{A}}$, i.e., the images of elements in $\tilde{\mathcal{A}}(3)$ are square-free. As ϱ is a uniformly growing morphisms, being square-free on $\tilde{\mathcal{A}}(3)$ implies, as proven in [5] and [3], that ϱ is a square-free morphism, i.e., it maps square-free words in $\tilde{\mathcal{A}}$ onto square-free words in $\mathcal{L}$, thus onto words in $\mathcal{A}$.

Lemma 1. The existence of an n-Brinkhuis triple pair implies the lower bound $s \ge 2^{1/(n-1)}$.

Proof. The existence of an n-Brinkhuis triple pair implies the inequality

$$a(mn) \geq 2^m a(m) \tag{16}$$

for any $m > 0$, because each square-free word of length m yields 2^m different square-free words of length mn. This means

$$\left(\frac{a(mn)}{a(m)}\right)^{\frac{1}{m}} \geq 2, \tag{17}$$

for any $m > 0$, and hence

$$s^{n-1} = \lim_{m\to\infty} \left(\frac{a(mn)}{a(m)}\right)^{\frac{1}{m}} \geq 2, \tag{18}$$

establishing the lower bound. □

The first lower bound was derived by Brinkhuis [4], who showed that $s \geq 2^{1/24}$ by constructing a 25-Brinkhuis triple pair consisting entirely of palindromic words. In that case, the conditions on the square-freeness of the images of three-letter words can be simplified to the square-freeness of the images of two-letter words and certain conditions on the "heads" and the "tails" of the words, which are easier to check explicitly. Brandenburg [3] produced a 22-Brinkhuis triple pair, which proves a lower bound of $s \geq 2^{1/21}$. For a long time, this was the best lower bound available, until, quite recently, Ekhad and Zeilberger [7] came up with a 18-Brinkhuis triple pair equivalent to

$$\begin{aligned} U^{(0)} &= 012021020102120210 & V^{(0)} &= 012021201020120210 = \bar{U}^{(0)} \\ U^{(1)} &= 120102101210201021 & V^{(1)} &= 120102012101201021 = \bar{U}^{(1)} \\ U^{(2)} &= 201210212021012102 & V^{(2)} &= 201210120212012102 = \bar{U}^{(2)}, \end{aligned} \tag{19}$$

thus establishing the bound $s \geq 2^{1/17}$. We note that the simpler definition for a Brinkhuis triple pair in [7], which is akin to Brinkhuis' original approach, is in fact incomplete, as it does not rule out a square that overlaps three adjacent words if the words are not palindromic. Nevertheless, the Brinkhuis triple (19) given in [7] is correct, and so is the lower bound $s \geq 2^{1/17} = 1.041\,616\ldots$ derived from it. In fact, it has been claimed (see [18]) that this is the optimal bound that can be obtained in this way, and this is indeed the case, see the discussion below.

It is interesting to note that, although this minimal-length Brinkhuis triple pair does not consist of palindromes, it is nevertheless invariant under reversion of words, as $V^{(i)} = \bar{U}^{(i)}$. In addition, it also shares the property with Brinkhuis' original triple that the words $U^{(1)}$, $V^{(1)}$ and $U^{(2)}$, $V^{(2)}$ which replace the letters 1 and 2, respectively, are obtained from $U^{(0)}$, $V^{(0)}$ by a global permutation τ of the three letters

$$\tau : \begin{cases} 0 \to 1 \\ 1 \to 2 \\ 2 \to 0 \end{cases} \tag{20}$$

i.e.,

$$U^{(2)} = \tau(U^{(1)}) = \tau^2(U^{(0)}), \quad V^{(2)} = \tau(V^{(1)}) = \tau^2(V^{(0)}). \tag{21}$$

Clearly, given any Brinkhuis triple pair, the sets of words obtained by reversion or by applying any permutation of the letters are again Brinkhuis triple pairs, so it may not be too surprising that a Brinkhuis triple pair of minimal length turns out to be invariant under these two operations.

4. Generalised Brinkhuis triples

As we cannot improve on the lower bound by constructing a shorter Brinkhuis triple, we proceed by generalising the notion. The idea is to allow for more than two words that replace each letter [8]. This leads to the following general definition.

Definition 2. An n-Brinkhuis (k_0, k_1, k_2)-triple is a set of $k_0 + k_1 + k_2$ square-free words $\mathcal{B} = \{\mathcal{B}^{(0)}, \mathcal{B}^{(1)}, \mathcal{B}^{(2)}\}$, $\mathcal{B}^{(i)} = \{w_j^{(i)} \in S(n) \mid 1 \le j \le k_i\}$, $k_i \ge 1$, such that, for any square-free word $ii'i''$ of length 3 and any $1 \le j \le k_i$, $1 \le j' \le k_{i'}$, $1 \le j'' \le k_{i''}$, the composed word $w_j^{(i)} w_{j'}^{(i')} w_{j''}^{(i'')}$ of length $3n$ is square-free.

Note that the definition reduces to definition 1 in the case $k_0 = k_1 = k_2 = 2$ of an "ordinary" Brinkhuis triple pair. From the set of square-free words of length 3, we deduce that the number of composed words that enter is $6k_0k_1k_2 + k_0^2(k_1 + k_2) + k_1^2(k_0 + k_2) + k_2^2(k_0 + k_1)$.

Lemma 2. The existence of an n-Brinkhuis (k_0, k_1, k_2)-triple implies the lower bound $s \ge k^{1/(n-1)}$, where $k = \min(k_0, k_1, k_2)$.

Proof. The proof proceeds as in lemma 1 above, with 2 replaced by $k = \min(k_0, k_1, k_2)$. □

As far as the lower bound is concerned, we do not gain anything by considering triples where the number of words k_0, k_1 and k_2 differ from each other. Nevertheless, the generality of definition 2 shall be of use below. In order to derive improved lower bounds, we shall in fact concentrate on a more restricted class of triples.

Definition 3. A special n-Brinkhuis k-triple is an n-Brinkhuis (k, k, k)-triple $\mathcal{B} = \{\mathcal{B}^{(0)}, \mathcal{B}^{(1)}, \mathcal{B}^{(2)}\}$ such that $\mathcal{B}^{(2)} = \tau(\mathcal{B}^{(1)}) = \tau^2(\mathcal{B}^{(0)})$ and $w \in \mathcal{B}^{(0)}$ implies $\bar{w} \in \mathcal{B}^{(0)}$, where τ is the permutation of letters defined in equation (20).

The first condition means that all words in $\mathcal{B}^{(1)}$ and $\mathcal{B}^{(2)}$ can be obtained from the words in $\mathcal{B}^{(0)}$ by the global permutation τ. The second condition implies that the words in $\mathcal{B}^{(0)}$, and hence also in $\mathcal{B}^{(1)}$ and $\mathcal{B}^{(2)}$, are either palindromes, i.e., $w = \bar{w}$, or occur as pairs $(w, \bar{w})$. This means that a special n-Brinkhuis k-triple is characterised by the set of palindromes $w = \bar{w} \in \mathcal{B}^{(0)}$ and by one member of each pairs of non-palindromic words $(w, \bar{w}) \in \mathcal{B}^{(0)}$. If there are k_p palindromes and k_n pairs in $\mathcal{B}^{(0)}$, then these generate a special Brinkhuis k-triple with $k = k_\mathrm{p} + 2k_\mathrm{n}$. We shall call $K = (k_\mathrm{p}, k_\mathrm{n})$ the signature of the special Brinkhuis k-triple, and denote a set of $k_\mathrm{p} + k_\mathrm{n}$ generating words by $\mathcal{G}$.

In order to obtain the best lower bound possible, we are looking for optimal choices of the length n and the number of words k. There are two possibilities, we may look for the largest k for given length n, or for the smallest length n for a given number k. This is made precise by the following definitions.

Definition 4. An optimal special n-Brinkhuis triple is a special n-Brinkhuis k-triple such that any special n-Brinkhuis l-triple has $l \le k$.

Definition 5. A minimal-length special Brinkhuis k-triple is a special n-Brinkhuis k-triple such that any special m-Brinkhuis k-triple has $m \ge n$.

If $\mathcal{B}$ is a special n-Brinkhuis k-triple, so is its image $\sigma(\mathcal{B})$ under any permutation $\sigma \in S_3$ of the three letters. Therefore, without loss of generality, we may assume that the first word $w_1^{(0)} \in \mathcal{B}$ starts with the letters 01. This has the following consequences on the other words of the triple.

Lemma 3. Consider a special n-Brinkhuis k-triple $\mathcal{B}$, with $n > 1$, such that the word $w_1^{(0)} \in \mathcal{B}^{(0)}$ starts with the letters 01. Then $n \ge 7$, and all words in $\mathcal{B}^{(0)}$ start with the three letters 012 and end on 210.

Proof. As $w_1^{(1)} = \tau(w_1^{(0)})$ and $w_1^{(2)} = \tau^2(w_1^{(0)})$, the words $w_1^{(1)}$ and $w_1^{(2)}$ start with letters 12 and 20, respectively. If $n = 2$, then $w_1^{(0)} w_1^{(1)} = 0112$ contains the square 11, so $n \ge 3$. Square-freeness of the composed words $w_j^{(0)} w_1^{(1)}$ and $w_j^{(0)} w_1^{(2)}$, $1 \le j \le k$, implies that the words $w_j^{(0)}$ have to end on

210, because $w = 210$ is the only word in $\mathcal{A}(3)$ such that $w12$ and $w20$ are both square-free. This in turn implies that all words in $\mathcal{B}^{(1)}$ and $\mathcal{B}^{(2)}$ end on 021 and 102, respectively. Now, square-freeness of the composed words $w_j^{(1)} w_{j'}^{(0)}$ and $w_j^{(2)} w_{j'}^{(0)}$ implies that the first three letter of $w_j^{(0)}$, for any $1 \leq j \leq k$, have to be $w = 012$, because this is the only word $\mathcal{A}(3)$ in such that $021w$ and $102w$ are both square-free. For $n = 3$ and $n = 4$, no such words exist, and the only possibility for $n = 6$ would be 012210 which is not square-free. For $n = 5$, the square-free word 01210 starts with 012 and ends on 210, but $w_1^{(0)} w_1^{(2)} w_1^{(0)} = 012102010201210$ contains the square of 0201. □

One can even say more about the "heads" and "tails" of the words in a special Brinkhuis triple. There are two possible choices for the forth letter of $w_1^{(0)}$, and both possibilities fix further letters and cannot appear within the same special Brinkhuis triple. Therefore, we can distinguish two different types of special Brinkhuis triples.

Proposition 1. Consider a special n-Brinkhuis k-triple $\mathcal{B}$, with $n > 1$, such that the word $w_1^{(0)} \in \mathcal{B}^{(0)}$ starts with the letters 01. Then $n \geq 13$ and either all words in $\mathcal{B}^{(0)}$ are of the form $012021 \ldots 120210$, or all words are of the form $012102 \ldots 201210$.

Proof. From lemma 3, we know that $n \geq 7$ and $w_1^{(0)}$ starts with 012 and ends on 210. There are now two choices for the forth letter. Let us consider the case that $w_1^{(0)}$ starts with 0120. Then $w_1^{(1)}$ starts with 1201. Now, from lemma 3, $w_1^{(2)}$ ends on 102, and square-freeness of $w_1^{(2)} w_j^{(0)}$ implies that $w_j^{(0)}$ starts with 01202, and hence with 012021. Now $w_1^{(1)}$ starts with 120102 and $w_1^{(2)}$ with 201210. From square-freeness of $w_j^{(0)} w_1^{(1)}$ and $w_j^{(0)} w_1^{(2)}$, we can rule out $w_j^{(0)}$ ends on 1210, because both possible extension 101210 and 201210 result in squares. Hence $w_j^{(0)}$ ends on 0210 and, from square-freeness of $w_j^{(0)} w_1^{(w)}$, it has to end on 20210, and thus on 120210.

Consider now the second possibility, i.e., $w_1^{(0)}$ starts with 0121. Necessarily, it then starts with 01210. As $w_1^{(1)}$ ends on 021, square-freeness of $w_1^{(1)} w_j^{(0)}$ implies that $w_j^{(0)}$ starts with 012102. Then $w_1^{(1)}$ starts with 120210 and $w_1^{(2)}$ with 201021. Square-freeness of $w_j^{(0)} w_1^{(1)}$ and $w_j^{(0)} w_1^{(2)}$ rules out an ending 0210 for $w_j^{(0)}$, as the only possible extension 20120 and 120210 both result in squares. Hence $w_j^{(0)}$ ends on 01210, and, from square-freeness of $w_j^{(0)} w_1^{(1)}$, actually has to end on 201210.

Now, in both cases it is obviously impossible to find square-free words of length $n = 8, 9, 10, 12$ that satisfy these conditions. For the first case, the one choice left for $n = 11$ is 01202120210, which contains the square of 1202. In the second case, the only word for $n = 11$ that satisfies the conditions is 01210201210. In this case, $w_1^{(0)} w_1^{(1)} = 012102012101202101202 1$ contains the square of 210120. □

The proofs of lemmas 3 and 1 are very explicit, but you may simplify the argument by realising that the conditions at both ends are essentially equivalent, as they follow from reversing the order of letters in combined words. The results restrict the number of words that have to be taken into account when looking for a special n-Brinkhuis k-triple. In what follows, we can restrict ourselves to the case $n \geq 13$. We denote the set of such square-free words by

$$\mathcal{A}_1(n) = \{w \in \mathcal{A}(n) \mid w = 012021 \ldots 120210\} \subset \mathcal{A}(n), \tag{22}$$

$$\mathcal{A}_2(n) = \{w \in \mathcal{A}(n) \mid w = 012102 \ldots 201210\} \subset \mathcal{A}(n), \tag{23}$$

and the number of such words by

$$a_1(n) := |\mathcal{A}_1(n)|, \tag{24}$$

$$a_2(n) := |\mathcal{A}_2(n)|. \tag{25}$$

We denote the number of palindromes by

$$a_{1\mathrm{p}}(n) := |\{w \in \mathcal{A}_1(n) \mid w = \bar{w}\}|, \tag{26}$$

$$a_{2\mathrm{p}}(n) := |\{w \in \mathcal{A}_2(n) \mid w = \bar{w}\}|, \tag{27}$$

and the number of non-palindromic pairs by

$$a_{1\mathrm{n}}(n) := \frac{1}{2}(a_1(n) - a_{1\mathrm{p}}(n)), \tag{28}$$

$$a_{2\mathrm{n}}(n) := \frac{1}{2}(a_2(n) - a_{2\mathrm{p}}(n)). \tag{29}$$

Clearly, there are no palindromic square-free words of even length, and thus $a_{1\mathrm{p}}(2n) = a_{2\mathrm{p}}(2n) = 0$, $a_{1\mathrm{n}}(2n) = a_1(2n)/2$ and $a_{2\mathrm{n}}(2n) = a_2(2n)/2$.

Now, for a word $w \in \mathcal{A}_1(n)$ or $w \in \mathcal{A}_2(n)$ to be a member of a special n-Brinkhuis triple, it must at least generate a triple by itself. This motivates the following definition.

Definition 6. A square-free palindrome $w = \bar{w} \in \mathcal{A}(n)$ is called admissible if w generates a special n-Brinkhuis 1-triple. A non-palindromic square-free word w of length n is admissible if w generates a special n-Brinkhuis 2-triple.

The hunt for optimal special n-Brinkhuis triples now proceeds in three steps.

Step 1. The first step consists of selecting all admissible words in $\mathcal{A}_1(n)$ and $\mathcal{A}_2(n)$. Let us denote the number of admissible palindromes in $\mathcal{A}_1(n)$ by $b_{1\mathrm{p}}(n)$ and the number of admissible non-palindromes by $2b_{1\mathrm{n}}(n)$, such that $b_{1\mathrm{n}}$ is the number of admissible pairs $(w, \bar{w})$ of non-palindromic words in $\mathcal{A}_1(n)$. Analogously, we define $b_{2\mathrm{p}}(n)$ and $b_{2\mathrm{n}}(n)$ for admissible words in $\mathcal{A}_2(n)$.

Step 2. The second step consists of finding all triples of admissible words that generate a special n-Brinkhuis triple. Depending on the number of palindromes k_p in that triple, which can be $k_\mathrm{p} = 0, 1, 2, 3$, these are special Brinkhuis k-triples with $k = 6, 5, 4, 3$, respectively. We denote the number of such admissible triples by $t_1(n)$ and $t_2(n)$. Here, we need to check the conditions of definition 2 for each triple. Using the structure of the special Brinkhuis triple, the number of words that have to be checked is substantially reduced from $12k^3$ to $k(2k^2 + k_\mathrm{p})$.

Step 3. The third and final step is purely combinatorial in nature, and does not involve any explicit checking of square-freeness of composed words. The reason is the following. A set $\mathcal{G}$, $|\mathcal{G}| \geq 3$, of words in $\mathcal{A}_1(n)$ or $\mathcal{A}_2(n)$, generates a special n-Brinkhuis triple if and only if all three-elemental subsets of $\mathcal{G}$ generate special n-Brinkhuis triples. This is obvious, because the conditions of definition 2 on three-letter words never involve more than three words simultaneously, so checking the condition for all subsets of three generating words is necessary and sufficient. Thus, the task is to find the largest sets of generating words such that all three-elemental subsets are contained in our list of admissible triples. In order to obtain an optimal special n-Brinkhuis triple, one has to take into account that $k = k_\mathrm{p} + 2k_\mathrm{n}$, so solutions with maximum number of generators are not necessarily optimal.

Even though this step is purely combinatorial and no further operations on the words are required, it is by far the most expensive part of the algorithm as the length n increases. Therefore, this is the part that limits the maximum length n that we can consider. Using a computer, we found the optimal Brinkhuis triples for $n \leq 41$. The results for generating words from $\mathcal{A}_1(n)$ are given in table 2, those for generating words taken from $\mathcal{A}_2(n)$ are displayed in table 3. We included partial results for $42 \leq n \leq 45$, in order to show how the number of admissible words grows for larger n. Even though we do not know the optimal n-Brinkhuis triples for these cases, it has to be expected that the value of k that can be achieved continues to grow, and it is certainly true for $n = 42$ where $k_\mathrm{opt} \geq 72$.

The optimal Brinkhuis triples are not necessarily unique, and the list also contains a case, $n = 29$, where there exist optimal Brinkhuis triples of both types. In general, several choices exist, which, however, cannot be combined into an even larger triple. A list of optimal n-Brinkhuis triples which at the same time are minimal-length Brinkhuis $k_{\rm opt}$ triples is given below.

Proposition 2. The following sets of words generate optimal and minimal-length Brinkhuis triples:

- $n = 13,\ k_{\rm p} = 1,\ k_{\rm n} = 0,\ k = 1$:

$$\mathcal{G}_{13} = \{0121021201210\} \tag{30}$$

- $n = 18,\ k_{\rm p} = 0,\ k_{\rm n} = 1,\ k = 2$:

$$\mathcal{G}_{18} = \{012021020102120210\} \tag{31}$$

- $n = 23,\ k_{\rm p} = 1,\ k_{\rm n} = 1,\ k = 3$:

$$\begin{aligned}\mathcal{G}_{23} = \{&01210212021012021201210,\\ &01210201021012021201210\}\end{aligned} \tag{32}$$

- $n = 25,\ k_{\rm p} = 1,\ k_{\rm n} = 2,\ k = 5$:

$$\begin{aligned}\mathcal{G}_{25} = \{&01210212021020120212012 10,\\ &01210201021012012021201210,\\ &01210212010210120212012 10\}\end{aligned} \tag{33}$$

- $n = 29,\ k_{\rm p} = 2,\ k_{\rm n} = 2,\ k = 6$:

$$\begin{aligned}\mathcal{G}_{29}^{(1)} = \{&01202120102012021020102120210,\\ &01202120121012021012102120210,\\ &01202102012101202120102120210,\\ &01202120102012021012102120210\}\end{aligned} \tag{34}$$

- $n = 29,\ k_{\rm p} = 0,\ k_{\rm n} = 3,\ k = 6$:

$$\begin{aligned}\mathcal{G}_{29}^{(2)} = \{&01210201021201020121021201210,\\ &01210201021202101201021201210,\\ &01210201021202102012021201210\}\end{aligned} \tag{35}$$

- $n = 30,\ k_{\rm p} = 0,\ k_{\rm n} = 4,\ k = 8$:

$$\begin{aligned}\mathcal{G}_{30} = \{&01210201021012010201202120 1210,\\ &01210201021201210201202120 1210,\\ &01210201021202102012102120 1210,\\ &01210212021012010201202120 1210\}\end{aligned} \tag{36}$$

- $n = 33,\ k_{\rm p} = 0,\ k_{\rm n} = 6,\ k = 12$:

$$\begin{aligned}\mathcal{G}_{33} = \{&01202102012101201021201210 2120210,\\ &01202102012102120102101210 2120210,\\ &01202102012102120121012010 2120210,\\ &01202120102012021012102010 2120210,\\ &01202120102012101202101210 2120210,\\ &01202120102101201021201210 2120210\}\end{aligned} \tag{37}$$

- $n = 35$, $k_{\mathrm{p}} = 2$, $k_{\mathrm{n}} = 8$, $k = 18$:

$$\begin{aligned}\mathcal{G}_{35} = \{&0120212010201210212012102010212021 0,\\ &0120212010210121020121012010212021 0,\\ &0120210201021201020120212010212021 0,\\ &0120210201021201020121012010212021 0,\\ &0120210201210120102012102010212021 0,\\ &0120210201210120212012102010212021 0,\\ &0120210201210212021012102010212021 0,\\ &0120212010201210120102101210212021 0,\\ &0120212010201210201021012010212021 0,\\ &0120212010212021020102101210212021 0\}\end{aligned} \tag{38}$$

- $n = 36$, $k_{\mathrm{p}} = 0$, $k_{\mathrm{n}} = 16$, $k = 32$:

$$\begin{aligned}\mathcal{G}_{36} = \{&0121020102101202120102101210212012 10,\\ &0121020102101202120121012012102120 1210,\\ &0121020102101210212010201210212012 10,\\ &0121020102101210212010210120212012 10,\\ &0121020102101210212021012012102120 1210,\\ &0121020102120121012010201210212012 10,\\ &0121020102120121012010210120212012 10,\\ &0121020102120121021201012102120 1210,\\ &0121020102120210120102101210212012 10,\\ &0121020102120210201021012012102120 1210,\\ &0121021201021012021201201210212012 10,\\ &0121021201021012102010210120212012 10,\\ &0121021201021012102120210120212012 10,\\ &0121021201210120102120210120212012 10,\\ &0121021201210120212010210120212012 10,\\ &0121021201210201021201020120212012 10\}\end{aligned} \tag{39}$$

- $n = 40$, $k_{\mathrm{p}} = 0$, $k_{\mathrm{n}} = 24$, $k = 48$:

Proof. The proof that these are indeed special Brinkhuis triples consist of checking the conditions of definition 2 explicitly. This has to be done by computer, as the number of symmetry-inequivalent composed words of length $3n$ that have to be checked for square-freeness is $k(2k^2 + k_\mathrm{p})$, which gives 549 445 words of length 123 for $\mathcal{G}_{41}$. A Mathematica [17] program `brinkhuistriples.m` that performs these checks accompanies this paper. This check is independent of the construction algorithm used to find the optimal triples. In order to show that these triples are indeed optimal, one has to go through the algorithm outlined above. This has been done, giving the results of tables 2 and 3. □

The triple for $n = 18$ is equivalent to the triple (19) of [7]. The corresponding lower bounds on s are

$$\begin{aligned} n = 13, k = 1 :&\quad s \geq 1^{1/12} = 1\\ n = 18, k = 2 :&\quad s \geq 2^{1/17} > 1.041616\\ n = 23, k = 3 :&\quad s \geq 3^{1/22} > 1.051204\\ n = 25, k = 5 :&\quad s \geq 5^{1/24} > 1.069359\\ n = 29, k = 6 :&\quad s \geq 6^{1/28} > 1.066083\\ n = 30, k = 8 :&\quad s \geq 8^{1/29} > 1.074338 \end{aligned}$$

$$\begin{aligned} n = 33, k = 12 : &\quad s \geq 12^{1/32} > 1.080747 \\ n = 35, k = 18 : &\quad s \geq 18^{1/34} > 1.088728 \\ n = 36, k = 32 : &\quad s \geq 32^{1/35} > 1.104089 \\ n = 40, k = 48 : &\quad s \geq 48^{1/39} > 1.104355 \\ n = 41, k = 65 : &\quad s \geq 65^{1/40} > 1.109999 \end{aligned} \tag{42}$$

Apparently, the largest value of n considered here yields the best lower bound. This suggests that the bound can be systematically improved by considering special Brinkhuis triples for longer words.

What about the restriction to special Brinkhuis triples? In general, it is not clear what the answer is, but for the Brinkhuis triple pair of [7] it can easily be checked by computer that one cannot find a shorter triple by lifting these restriction. In fact, this follows from the following stronger result which is easier to check.

Lemma 4. An n-Brinkhuis $(2, 1, 1)$-triple requires $n > 17$.

Proof. This can be checked by computer. The number of square-free words of length $n = 17$ is 1044. However, we do not need to check all 1044^4 possibilities. Without loss of generality, we may restrict one of the four words to start with the letters 01, leaving only $1044/6 = 174$ choices for this word. Furthermore, the two words in $\mathcal{B}^{(0)}$ may be interchanged, as well as the other two words; so it is sufficient to consider one order of words in both cases. No n-Brinkhuis $(2, 1, 1)$-triple was found for $n \leq 17$. □

5. Concluding remarks

By enumerating square-free ternary words up to length 110 and by constructing generalised Brinkhuis triples, we improved both upper and lower bounds for the number of ternary square-free words. The resulting bounds for the exponential growth rate s (6) are

$$1.109999 < 65^{1/40} \leq s \leq 8\,416\,550\,317\,984^{\frac{1}{108}} < 1.317278. \tag{43}$$

The main difficulty in improving the lower bound further is caused by the combinatorial step in the algorithm to find optimal special Brinkhuis triples. The data in tables 2 and 3 suggest that generators from the set $\mathcal{A}_1(n)$ (22) are more likely to provide optimal n-Brinkhuis triples for large n than generators from the set $\mathcal{A}_2(n)$ (23). It would be interesting to know whether, in principle, the lower bound obtained in this way eventually converges to the actual value of s.

Acknowledgment

The author would like to thank Jean-Paul Allouche for useful discussions during a workshop at Oberwolfach in May 2001. The author gratefully acknowledges comments from Shalosh B. Ekhad and Doron Zeilberger, who pointed out an error in a previous attempt to improve the lower bound.

*                                               *
*    CONTENT:                                   *
*    This program contains definitions to       *
*    check generalised Brinkhuis triples.       *
*    It accompanies the article "Improved       *
*    bounds on the number of ternary            *
*    square-free words" by Uwe Grimm.           *
*    The Brinkhuis triples derived in the       *
*    paper are explicitly contained.            *
*                                               *
*    The program provides two main routines,    *
*    BrinkhuisTripleCheck and                   *
*    BrinkhuisSpecialTripleCheck. The latter    *
*    exploits the structure of a special        *
*    Brinkhuis triple to reduce the number      *
*    of words that have to be checked for       *
*    square-freeness.                           *
*                                               *
*    If the program is executed in the          *
*    form, it starts to check the special       *
*    Brinkhuis triples presented in the         *
*    paper mentioned above. You may have        *
*    to be patient if you are interested        *
*    in the result for the largest triples,     *
*    as it will take quite a while (several     *
*    days on a Pentium 1GHz machine) to         *
*    complete all checks.                       *
*                                               *
*    DISCLAIMER:                                *
*    The program has been tested by the         *
*    author, but no guarantee can be given      *
*    that results are indeed correct - so       *
*    use at your own risk!                      *
*                                               *

Counting Peaks at Height *k* in a Dyck Path

Toufik Mansour

LaBRI
Université Bordeaux 1
351, cours de la Libération
33405 Talence Cedex, France

Abstract: A Dyck path is a lattice path in the plane integer lattice Z x Z consisting of steps (1,1) and (1,-1), which never passes below the *x*-axis. A peak at height *k* on a Dyck path is a point on the path with coordinate *y*=*k* that is immediately preceded by a (1,1) step and immediately followed by a (1,-1) step. In this paper we find an explicit expression for the generating function for the number of Dyck paths starting at (0,0) and ending at (2*n*,0) with exactly *r* peaks at height *k*. This allows us to express this function via Chebyshev polynomials of the second kind and the generating function for the Catalan numbers.

Abstract

A Dyck path is a lattice path in the plane integer lattice $\mathbb{Z} \times \mathbb{Z}$ consisting of steps $(1,1)$ and $(1,-1)$, which never passes below the x-axis. A peak at height k on a Dyck path is a point on the path with coordinate $y = k$ that is immediately preceded by a $(1,1)$ step and immediately followed by a $(1,-1)$ step. In this paper we find an explicit expression for the generating function for the number of Dyck paths starting at $(0,0)$ and ending at $(2n,0)$ with exactly r peaks at height k. This allows us to express this function via Chebyshev polynomials of the second kind and the generating function for the Catalan numbers.

Keywords: Dyck paths, Catalan numbers, Chebyshev polynomials.

1. Introduction and main results

The *Catalan sequence* is the sequence

$$\{C_n\}_{n\geq 0} = \{1, 1, 2, 5, 14, 132, 429, 1430, \dots\},$$

where $C_n = \frac{1}{n+1}\binom{2n}{n}$ is called the nth *Catalan number*. The generating function for the Catalan numbers is denoted by $C(x) = \frac{1-\sqrt{1-4x}}{2x}$. The Catalan numbers provide a complete answer to the problem of counting certain properties of more than 66 different combinatorial structures (see Stanley [S, Page 219 and Exercise 6.19]). The structure of use to us in the present paper is Dyck paths.

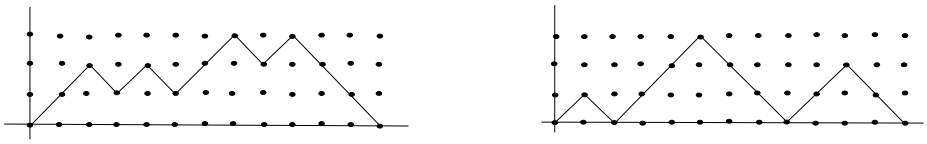

FIGURE 1. Two Dyck paths.

Chebyshev polynomials of the second kind are defined by

$$U_r(\cos\theta) = \frac{\sin(r+1)\theta}{\sin\theta}$$

for $r \geq 0$. Evidently, $U_r(x)$ is a polynomial of degree r in x with integer coefficients. Chebyshev polynomials were invented for the needs of approximation theory, but are also widely used in various other branches of mathematics, including algebra, combinatorics, number theory, and lattice paths (see [K, Ri]). For $k \geq 0$ we define $R_k(x)$ by

$$R_k(x) = \frac{U_{k-1}\left(\frac{1}{2\sqrt{x}}\right)}{\sqrt{x}U_k\left(\frac{1}{2\sqrt{x}}\right)}.$$

For example, $R_0(x) = 0$, $R_1(x) = 1$, and $R_2(x) = 1/(1-x)$. It is easy to see that for any k, $R_k(x)$ is a rational function in x.

A *Dyck path* is a lattice path in the plane integer lattice $\mathbb{Z} \times \mathbb{Z}$ consisting of up-steps $(1,1)$ and down-steps $(1,-1)$, which never passes below the x-axis (see Figure 1). Let P be a Dyck path; we define the *weight* of P to be the product of the weights of all its steps, where the weight of every step (up-step or down-step) is $\sqrt{x}$. For example, Figure 1 presents two Dyck paths, each of length 12 and weight x^6.

A point on the Dyck path is called a *peak at height* k if it is a point with coordinate $y = k$ that is immediately preceded by a up-step and immediately followed by a down-step. For example, Figure 1 presents two Dyck paths; the path on the left has two peaks at height 2 and two peaks at height 3; and the path on the right has one peak at height 1, one peak at height 2, and one peak at height 3. A point on the Dyck path is called a *valley at height* k if it is a point with coordinate $y = k$ that is immediately preceded by down-step and immediately followed by up-step. For example, in Figure 1, the path on the left has two valleys at height 1 and one valley at height 2, and the path on the right has only two valleys at height 0. The number of all Dyck paths starting at $(0,0)$ and ending at $(2n,0)$ with exactly r peaks (resp. valleys) at height k we denote by $\mathrm{peak}_k^r(n)$ (resp. $\mathrm{valley}_k^r(n)$). The corresponding generating function is denoted by $\mathrm{Peak}_k^r(x)$ (resp. $\mathrm{Valley}_k^r(x)$).

Deutsch [D] found the number of Dyck paths of length $2n$ starting and ending on the x-axis with no peaks at height 1 is given by the nth Fine number: 1, 0, 1, 2, 6, 18, 57, ... (see [D, DS, F] and [SP, Sequence M1624]). Recently, Peart and Woan [PW] gave a complete answer for the number of Dyck paths of length $2n$ starting and ending on the x-axis with no peaks at height k. This result can be formulated as follows.

Theorem 1.1. (see [PW, Section 2]) *The generating function for the number of Dyck paths of length $2n$ starting and ending on the x-axis with no peaks at height k is given by*

$$\cfrac{1}{1-\cfrac{x}{1-\cfrac{x}{1-\cfrac{\ddots}{1-\cfrac{x}{1-x^2C^2(x)}}}}},$$

where the continued fraction contains exactly k levels.

Theorem 1.1 is in fact a simple consequence of Theorem 1.2 (as we are going to show in Section 3).

Theorem 1.2. (see [RV, Proposition 1]) *For given a Dyck path P we give every up-step the weight 1, every down-step from height k to height $k-1$ not following a peak the weight λ_k, and every down-step following a peak of height k the weight μ_k. The weight of $w(P)$ of the path P is the product of the weights of its steps. Then the generating function $\sum_P w(P)$, where the sum over all the Dyck paths, is given by*

$$\cfrac{1}{1-(\mu_1-\lambda_1)-\cfrac{\lambda_1}{1-(\mu_2-\lambda_2)-\cfrac{\lambda_2}{1-(\mu_3-\lambda_3)-\ddots}}}$$

In this paper we find an explicit formulas for the generating functions $\mathrm{Peak}_k^r(x)$ and $\mathrm{Valley}_k^r(x)$ for any $k, r \geq 0$. This allows us to express these functions via Chebyshev polynomials of the second kind $U_k(x)$ and generating function for the Catalan numbers $C(x)$. The main result of this paper can be formulated as follows:

Main Theorem 1.1.

(*i*) *For all $k \geq 2$,*

$$\mathrm{Peak}_k^r(x) = \mathrm{Valley}_{k-2}^r(x);$$

(*ii*) *For all $k, r \geq 0$,*

$$\mathrm{Valley}_k^r(x) = \delta_{r,0}R_{k+1}(x) + \frac{x^rC^{r+1}(x)}{U_{k+1}^2\left(\frac{1}{2\sqrt{x}}\right)\Big(1-x(R_{k+1}(x)-1)C(x)\Big)^{r+1}};$$

(*iii*) *For all* $r \geq 0$,

$$\mathrm{Peak}_1^r(x) = \delta_{r,0} + \frac{x^{3r+2}C^{2r+2}(x)}{(1-x^2C^2(x))^{r+1}}.$$

We give two proofs of this result. The first proof, given in Section 2, uses a decomposition of the paths under consideration, while the second proof, given in Section 3, uses the continued fraction theorem due to Roblet and Viennot (see Theorem 1.2) as the starting point.

Remark 1.3. *By the first part and the second part of the Main Theorem, we obtain an explicit expression for the generating function for the number of Dyck paths starting at* $(0,0)$ *and ending on the* x*-axis with no peaks at height* $k \geq 2$*, namely*

$$\mathrm{Peak}_k^0(x) = R_{k-1}(x) + \frac{x^r C^{r+1}(x)}{U_{k-1}^2\left(\frac{1}{2\sqrt{x}}\right)\left(1-x(R_{k-1}(x)-1)C(x)\right)^{r+1}}.$$

We also provide a combinatorial explanation for certain facts in Main Theorem. For example, we provide a combinatorial proof for the fact (*ii*) in the Main Theorem for $r = k = 0$.

Acknowledgments. The author expresses his appreciation to the referees for their careful reading of the manuscript and helpful suggestions.

2. Proofs: directly from definitions

In this section we present a proof for the Main Theorem which is based on the definitions of the Dyck paths.

Proof of the Main Theorem(*i*). We start by proving the first part of the Main Theorem by introducing a bijection Ψ between the set of Dyck paths of length $2n$ with r peaks at height k and the set of Dyck paths of length $2n$ with r valleys at height $k-2$.

Theorem 2.1. $\mathrm{Peak}_k^r(x) = \mathrm{Valley}_{k-2}^r(x)$ *for all* $k \geq 2$.

Proof. Let $P = P_1, P_2, \ldots, P_{2n}$ be a Dyck path of length $2n$ with exactly r peaks at height $k \geq 2$ where P_j are the points of the path P. For any point P_j we define another point $\Psi(P_j) = Q_j$ as follows. If P_j appears as a point of a valley at height $k-2$ then we define $Q_j = P_j + (0,2)$. If P_j appear as a point of a peak at height k then we define $Q_j = P_j - (0,2)$ (this is possible since $k \geq 2$). Otherwise, we define $Q_j = P_j$. Therefore, we obtain a new path $Q = Q_1, Q_2, \ldots, Q_{2n}$, and by definition of Q it is easy to see that Q is a Dyck path of length $2n$ with exactly r valleys at height $k-2$ (see Figure 2).

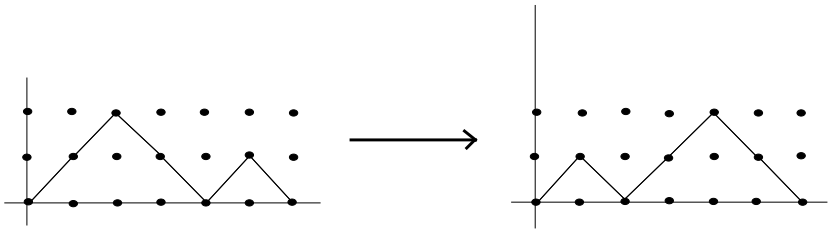

FIGURE 2. Bijection Ψ.

In fact, it is easily verified that the map which maps P to Q is a bijection. This establishes the theorem. □

Formula for $\text{Valley}_0^0(x)$. Let P be a Dyck path with no valleys at height 0. It is easy to see that P has no valleys at height 0 if and only if there exists a Dyck path P' of length $2n-2$ such that

$$P = \text{up-step}, P', \text{down-step}.$$

Let P'' be the path that results by shifting P' by $(-1,-1)$. Then the map Θ which sends $P \to P''$ is a bijection between the set of all Dyck paths starting at $(0,0)$ and ending at $(2n,0)$ with no valleys, and the set of all Dyck paths starting at point $(0,0)$ and ending at $(2n-2,0)$. Hence

$$\text{Valley}_0^0(x) = 1 + xC(x),$$

where we count 1 for the empty path, x for the up-step and the down-step, and $C(x)$ for all Dyck paths P''.

Proof of the Main Theorem(ii). First of all, let us present two facts. The first fact concerns the generating function for the number of Dyck paths from the southwest corner of a rectangle to the northeast corner.

Fact 2.2. (see [K, Theorem A2 with Fact A3]) *Let $k \geq 0$. The generating function for the number of Dyck paths which lie between the lines $y = k$ and $y = 0$, starting at $(0,0)$ and ending at (n,k) is given by*

$$F_k(x) := \frac{1}{\sqrt{x}U_{k+1}\left(\frac{1}{2\sqrt{x}}\right)}.$$

The second fact concerns the generating function for the number of Dyck paths starting at $(a,k+1)$ and ending at $(a+n,k+1)$ with no valleys at height k.

Fact 2.3. *The generating function for the number of Dyck paths starting at $(a,k+1)$ and ending at $(a+n,k+1)$ with no valleys at height k is given by*

$$\frac{C(x)}{1-x(R_{k+1}(x)-1)C(x)}.$$

Proof. Let P be a Dyck path starting at $(k+1,0)$ and ending at $(k+1,n)$ with no valleys at height k. It is easy to see that P has a unique decomposition of the form

$$P = W_1, \text{down-step}, V_1, \text{up-step}, W_2, \text{down-step}, V_2, \ldots, \text{up-step}, W_m,$$

where the following conditions holds for all j:

(*i*) W_j is a path consisting of up-steps and down-steps starting and ending at height $k+1$ and never passes below the height $k+1$;

(*ii*) V_j is a path consisting of up-step and down-steps starting and ending at height k and never passes over the height k (see Figure 3).

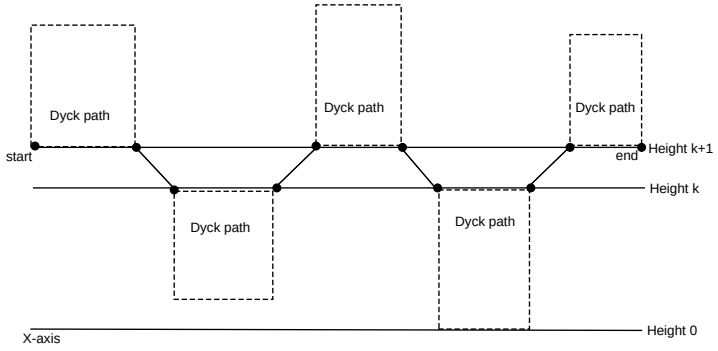

FIGURE 3. A decomposition of a Dyck path starting at $(a, k+1)$ and ending at $(a+n, k+1)$ with no valleys at height k.

Using [K, Theorem 2] we get that the generating function for the number of paths of type V_j (shift for a Dyck path) is given by $R_{k+1}(x) - 1$. Using the fact that W_j is a shift for a Dyck paths starting and ending on the x-axis we obtain the generating function for the number of Dyck paths of type W_j is given by $C(x)$. If we sum over all the possibilities of m then we have

$$C(x) \sum_{m \geq 0} \left(xC(x)(R_{k+1}(x) - 1) \right)^m = \frac{C(x)}{1 - x(R_{k+1}(x) - 1)C(x)}.$$

□

Now we are ready to prove the second part of the Main Theorem.

Theorem 2.4. *The generating function* $\mathrm{Valley}_k^r(x)$ *is given by*

$$\delta_{r,0}R_{k+1}(x) + \frac{x^r C^{r+1}(x)}{U_{k+1}^2\left(\frac{1}{2\sqrt{x}}\right)\Big(1-x(R_{k+1}(x)-1)C(x)\Big)^{r+1}}.$$

Proof. Let P be a Dyck path starting $(0,0)$ and ending at $(2n,0)$ with exactly r valleys at height k. It is easy to see that P has a unique decomposition of the form

$$P = E_1, \text{up-step}, D_0, \text{down-step}, \text{up-step}, D_1, \text{down-step}, \text{up-step}, \ldots, D_r, \text{down-step}, E_2,$$

where the following conditions holds:

- (i) E_1 is a Dyck path that lies between the lines $y = k$ and $y = 0$, starting at $(0,0)$, and ending at point on height k;
- (ii) D_j is a Dyck path starting and ending at points on height $k+1$ without valleys at height k, for all j;
- (iii) E_2 is a Dyck path that lies between the lines $y = k$ and $y = 0$, starting at point on height k, and ending at $(2n,0)$.

Using Fact 2.2 and Fact 2.3 we get the the desired result for all $r \geq 1$. Now, if we assume that $r = 0$, then we must consider another possibility which is that all the Dyck paths lie between the lines $y = k$ and $y = 0$, starting at $(0,0)$, and ending on the x-axis. Hence, using [K, Theorem 2] we get that the generating function for the number of these paths is given by $R_{k+1}(x)$. □

As a corollary of the Main Theorem(ii) for $k = 0$ (using [M, Example 1.18]) we get

Theorem 2.5. *For all* $r \geq 0$,

$$\mathrm{Valley}_0^r(x) = \delta_{r,0} + x^{r+1}C^{r+1}(x).$$

In other words, the number of Dyck paths starting at $(0,0)$ *and ending at* $(2n,0)$ *with exactly* r *valleys at height* 0 *is given by*

$$\frac{r+1}{n}\binom{2n-r-1}{n+1}.$$

Proof of the Main Theorem(iii). If we merge the first two parts of Main Theorem, then we get an explicit formula for $\mathrm{Peak}_k^r(x)$ for all $r \geq 0$ and $k \geq 2$. Besides, by definition there are no peaks at height 0. Thus, it is left to find $\mathrm{Peak}_1^r(x)$ for all $r \geq 0$.

Theorem 2.6. *For all* $r \geq 0$,

$$\mathrm{Peak}_1^r(x) = \delta_{r,0} + \frac{x^{3r+2}C^{2r+2}(x)}{(1-x^2C^2(x))^{r+1}}.$$

Proof. Let P be a Dyck path starting at $(0,0)$ and ending at $(2n,0)$ with exactly r peaks at height 1. It is easy to see that P has a unique decomposition of the form

$$P = D_0, \text{up-step}, \text{down-step}, D_1, \text{up-step}, \text{down-step}, \ldots, \text{up-step}, \text{down-step}, D_r,$$

where D_j is a nonempty Dyck path starting and ending at point on the x-axis with no peaks at height 1. Hence, the rest is easy to obtain by using [D]. □

For example, for $r = 0$ the above theorem yields the main result of [D].

3. Proofs: Directly from Theorem 1.2

In this section we present another proof for the Main Theorem which is based on Roblet and Viennot [RV, Proposition 1] (see Theorem 1.2).

Let $\lambda_j = x$ for all j, $\mu_j = x$ for all $j \neq k$, and $\mu_k = z$. Theorem 1.2 yields

$$\sum_{r\geq 0} \mathrm{Peak}_k^r(x)z^r = \cfrac{1}{1-\cfrac{x}{1-\cfrac{x}{1-\ddots\cfrac{}{1-\cfrac{x}{1-\cfrac{x}{1-(z-x)-\cfrac{x}{1-\cfrac{x}{1-\cfrac{x}{1-\ddots}}}}}}}}}, \tag{1}$$

where z appears in the kth level. On the other hand, $xC^2(x) = C(x) - 1$, we have that

$$C(x) = \cfrac{1}{1-\cfrac{x}{1-\cfrac{x}{1-\ddots}}}. \tag{2}$$

Using the identities (1) and (2) with $xC^2(x) = C(x) - 1$ we get

Theorem 3.1. *The generating function* $\sum_{r\geq 0} \mathrm{Peak}_k^r(x)z^r$ *is given by*

$$\cfrac{1}{1-\cfrac{x}{1-\cfrac{x}{1-\ddots\cfrac{}{1-\cfrac{x}{1-\cfrac{x}{1-z-x^2C^2(x)}}}}}},$$

where the continued fraction contains exactly k levels.

For example, Theorem 3.1 yields for $z = 0$ the generating function $\mathrm{Peak}_k^0(x)$ as in the statement of Theorem 1.1. More generally, Theorem 3.1 yields an explicit expression for $\mathrm{Peak}_k^r(x)$ for any $r \geq 1$ by using the following lemma.

Lemma 3.2. *For all $k \geq 1$,*

$$\cfrac{1}{1-\cfrac{x}{1-\cfrac{x}{1-\cfrac{\ddots}{1-\cfrac{x}{1-z-xA}}}}} = R_k(x) \cdot \frac{1 - zR_{k-1}(x) - xAR_{k-1}(x)}{1 - zR_k(x) - xAR_k(x)}.$$

where the continued fraction contains exactly k levels.

Proof. Immediately, by using the identity $R_{m+1}(x) = 1/(1 - xR_m(x))$ and induction on k. □

Therefore, using Theorem 3.1, the above lemma, and the identity $R_{m+1}(x) = 1/(1 - xR_m(x))$, together with definitions of $R_k(x)$, we get the explicit expression for the generating function $\mathrm{Peak}_k^r(x)$ for any $r \geq 1$ (see the Main Theorem).

sellersj@math.psu.edu

Abstract

In this brief note, we prove a result which was "accidentally" found thanks to Neil Sloane's Online Encyclopedia of Integer Sequences. Namely, we prove via elementary techniques that the number of domino tilings of the graph $W_4 \times P_{n-1}$ equals $f_n p_n$, the product of the n^{th} Fibonacci number and the n^{th} Pell number.

1 Introduction

Recently I received an electronic mail message [1] in which I was notified that a pair of duplicate sequences existed in Neil Sloane's Online Encyclopedia of Integer Sequences [3]. This involved sequence A001582 and the former sequence A003763. One of these sequences was described as the product of Fibonacci and Pell numbers, while the other was the number of domino tilings of the graph $W_4 \times P_{n-1}$.

I soon notified Neil Sloane of this fact and he promptly combined the two sequence entries into one entry, A001582. Upon combining these two entries, he also noted that it was not officially a theorem (that the product of the Fibonacci and Pell numbers was always equal to the number of domino tilings of $W_4 \times P_{n-1}$), but that is was "certainly true."

The primary goal of this short note is to prove this result so that its status is indeed a theorem. We close the paper by noting two other results relating domino tiling sequences in [2] with Fibonacci numbers.

Before proving the main result, we supply some definitions and notation for the sake of completeness. First, we note that the graph W_4 is $K_4 - e$. Moreover, the graph P_n is the path graph on n vertices. The Fibonacci numbers A000045 are defined as the sequence of integers

$$f_1 = 1, f_2 = 1, \text{ and } f_{n+2} = f_{n+1} + f_n \text{ for all } n \geq 0. \tag{1}$$

The Pell numbers A000129 are defined as the sequence of integers

$$p_1 = 1, p_2 = 2, \text{ and } p_{n+2} = 2p_{n+1} + p_n \text{ for all } n \geq 0. \tag{2}$$

2 The Results

Theorem 2.1. *The number of domino tilings of $W_4 \times P_{n-1}$ equals $f_n p_n$ for all $n \geq 2$.*

Proof. Thanks to an article of Faase [2, page 146], we know that the number of domino tilings of $W_4 \times P_{n-1}$, which we will denote by c_n, satisfies $c_2 = 2$, $c_3 = 10$, $c_4 = 36$, $c_5 = 145$ and

$$c_{n+4} - 2c_{n+3} - 7c_{n+2} - 2c_{n+1} + c_n = 0 \tag{3}$$

for all $n \geq 2$. (This is slightly different than the notation used in Faase, where he defines a function $C(n)$ wherein $c_n = C(n-1)$ and then does all work in terms of $C(n)$ rather than c_n.)

It is easy to check that $f_n p_n$ satisfies the initial conditions above. Hence, we focus on checking that $f_n p_n$ satisfies (3).

Repeated applications of (1) and (2) yield

$$f_{n+2} = f_n + f_{n+1}, \ f_{n+3} = f_n + 2f_{n+1}, \text{ and } f_{n+4} = 2f_n + 3f_{n+1} \tag{4}$$

while

$$p_{n+2} = p_n + 2p_{n+1}, \ p_{n+3} = 2p_n + 5p_{n+1}, \text{ and } p_{n+4} = 5p_n + 12p_{n+1}. \tag{5}$$

We now substitute the findings in (4) and (5) into the left-hand side of (3) and simplify:

$$\begin{aligned}
& f_{n+4}p_{n+4} - 2f_{n+3}p_{n+3} - 7f_{n+2}p_{n+2} - 2f_{n+1}p_{n+1} + f_n p_n \\
= \ & (2f_n + 3f_{n+1})(5p_n + 12p_{n+1}) - 2(f_n + 2f_{n+1})(2p_n + 5p_{n+1}) - 7(f_n + f_{n+1})(p_n + 2p_{n+1}) \\
& -2f_{n+1}p_{n+1} + f_n p_n \\
= \ & f_n p_n(10 - 4 - 7 + 1) + f_{n+1}p_n(15 - 8 - 7) + f_n p_{n+1}(24 - 10 - 14) + f_{n+1}p_{n+1}(36 - 20 - 14 - 2) \\
= \ & 0
\end{aligned}$$

Thus, $c_n = f_n p_n$ for all $n \geq 2$ and the proof is complete. □

We note that at least two other domino tiling sequences that appear in [2] are also closely related to Fibonacci numbers.

We first consider sequence A003775 which appears in [2, p. 147] in relationship to the number of domino tilings of $P_5 \times P_{2n}$. Based on this sequence, we define $d_1 = 1, d_2 = 8, d_3 = 95, d_4 = 1183$ and

$$d_{n+4} - 15d_{n+3} + 32d_{n+2} - 15d_{n+1} + d_n = 0 \tag{6}$$

for all $n \geq 1$. Computational experimentation indicates that $f_{2n-1} \mid d_n$ for several values of n. This leads to the following theorem:

Theorem 2.2. *For all $n \geq 1$, $d_n = g_n h_n$ where g_n is the n^{th} term in the sequence A004253 and $h_n = f_{2n-1}$ for all $n \geq 1$.*

Remark: Note that A004253 is related to the number of domino tilings in $K_3 \times P_{2n}$ and $S_4 \times P_{2n}$ as noted by Faase in [2, pp. 146-147]. Moreover, A004253 is quite similar to A028475.

Proof. The proof here follows a similar line of argument to that of Theorem 2.1. From the information given in A004253, we know that

$$g_1 = 1, g_2 = 4, \text{ and } g_{n+2} = 5g_{n+1} - g_n. \tag{7}$$

Moreover, we have

$$h_1 = 1, h_2 = 2, \text{ and } h_{n+2} = 3h_{n+1} - h_n. \tag{8}$$

It is easy to check that $d_n = g_n h_n$ for $1 \leq n \leq 4$, so we focus our attention on the recurrence (6). We know from (7) that

$$g_{n+2} = 5g_{n+1} - g_n, \ g_{n+3} = 24g_{n+1} - 5g_n, \text{ and } g_{n+4} = 115g_{n+1} - 24g_n \tag{9}$$

while (8) yields

$$h_{n+2} = 3h_{n+1} - h_n, \ h_{n+3} = 8h_{n+1} - 3h_n, \text{ and } h_{n+4} = 21h_{n+1} - 8h_n. \tag{10}$$

We now substitute the information from (9) and (10) into the left-hand side of (6) and obtain the following:

$$\begin{aligned}
& g_{n+4}h_{n+4} - 15g_{n+3}h_{n+3} + 32g_{n+2}h_{n+2} - 15g_{n+1}h_{n+1} + g_n h_n \\
= \ & (115g_{n+1} - 24g_n)(21h_{n+1} - 8h_n) - 15(24g_{n+1} - 5g_n)(8h_{n+1} - 3h_n) + 32(5g_{n+1} - g_n)(3h_{n+1} - h_n) \\
& -15g_{n+1}h_{n+1} + g_n h_n \\
= \ & g_n h_n(192 - 225 + 32 + 1) + g_{n+1}h_n(-920 + 1080 - 160) \\
& +g_n h_{n+1}(-504 + 600 - 96) + g_{n+1}h_{n+1}(2415 - 2880 + 480 - 15) \\
= \ & 0
\end{aligned}$$

This completes the proof.

□

Finally, we consider the last sequence of values in [2], which is related to the number of domino tilings of $P_8 \times P_n$ and appears as A028470 in [3]. The first 32 values of the sequence are as follows:

n	C_n
1	1
2	34
3	153
4	2245
5	14824
6	167089

Abstract

We prove that the Hankel transformation of a sequence whose elements are the sums of two adjacent Catalan numbers is a subsequence of the Fibonacci numbers. This is done by finding the explicit form for the coefficients in the three-term recurrence relation that the corresponding orthogonal polynomials satisfy.

1. Introduction

Let $A = \{a_0, a_1, a_2, ...\}$ be a sequence of real numbers. The Hankel matrix generated by A is the infinite matrix $H = [h_{i,j}]$, where $h_{i,j} = a_{i+j-2}$, i.e.,

$$H = \begin{bmatrix} a_0 & a_1 & a_2 & a_3 & \dots \\ a_1 & a_2 & a_3 & a_4 & \dots \\ a_2 & a_3 & a_4 & a_5 & \dots \\ a_3 & a_4 & a_5 & a_6 & \dots \\ a_4 & a_5 & a_6 & a_7 & \dots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix}$$

The *Hankel matrix* H_n *of order* n is the upper-left $n \times n$ submatrix of H and the *Hankel determinant of order* n of A, denoted by h_n, is the determinant of the corresponding Hankel matrix.

For a given sequence $A = \{a_0, a_1, a_2, ...\}$, the *Hankel transform* of A is the corresponding sequence of Hankel determinants $\{h_0, h_1, h_2, \dots\}$ (see Layman [5]).

The elements of the sequence in which we are interested (A005807 of the On-Line Encyclopedia of Integer Sequences (EIS) [10], also INRIA [3]) are the sums of two adjacent Catalan numbers:

$$\begin{aligned} a_n &= c(n) + c(n+1) = \frac{1}{n+1}\binom{2n}{n} + \frac{1}{n+2}\binom{2n+2}{n+1} \\ &= \frac{(2n)!(5n+4)}{n!(n+2)!} \qquad (n = 0, 1, 2, \dots). \end{aligned}$$

This sequence starts as follows:

$$2, \quad 3, \quad 7, \quad 19, \quad 56, \quad 174 \dots$$

In a comment stored with sequence A001906 Layman conjectured that the Hankel transformation of $\{a_n\}_{n\geq 0}$ equals the sequence A001906, i.e., the bisection of Fibonacci sequence. In this paper we shall prove a slight generalization of Layman's conjecture.

The generating function $G(x)$ for the sequence $\{a_n\}_{n\geq 0}$ is given by

$$G(x) = \sum_{n=0}^{\infty} a_n x^n = \frac{1}{x}\left(\frac{(1-\sqrt{1-4x})(1+x)}{2x} - 1\right) \tag{1}$$

It is known (for example, see Krattenthaler [4]) that the Hankel determinant h_n of order n of the sequence $\{a_n\}_{n\geq 0}$ equals

$$h_n = a_0^n \beta_1^{n-1} \beta_2^{n-2} \cdots \beta_{n-2}^2 \beta_{n-1}, \tag{2}$$

where $\{\beta_n\}_{n\geq 1}$ is the sequence given by:

$$G(x) = \sum_{n=0}^{\infty} a_n x^n = \cfrac{a_0}{1 + \alpha_0 x - \cfrac{\beta_1 x^2}{1 + \alpha_1 x - \cfrac{\beta_2 x^2}{1 + \alpha_2 x - \cdots}}} \tag{3}$$

The sequences $\{\alpha_n\}_{n\geq 0}$ and $\{\beta_n\}_{n\geq 1}$ are the coefficients in the recurrence relation

$$P_{n+1}(x) = (x-\alpha_n)P_n(x) - \beta_n P_{n-1}(x)$$

where $\{P_n(x)\}_{n\geq 0}$ is the monic polynomial sequence orthogonal with respect to the functional L determined by

$$L[x^n] = a_n \quad (n = 0, 1, 2, \ldots). \tag{4}$$

In the next section this functional is constructed and a theorem concerning the polynomials $\{P_n(x)\}_{n\geq 0}$ and the sequences $\{\alpha_n\}_{n\geq 0}$ and $\{\beta_n\}_{n\geq 1}$ is proved.

2. Main Theorem

We would like to express $L[f]$ in the form:

$$L[f(x)] = \int_R f(x)d\psi(x),$$

where $\psi(x)$ is a distribution, or, even more, to find the weight function $w(x)$ such that $w(x) = \psi'(x)$.

Denote by $F(z)$ the function

$$F(z) = \sum_{k=0}^{\infty} a_k z^{-k-1},$$

From the generating function (1), we have:

$$F(z) = z^{-1}\ G\big(z^{-1}\big) = \frac{1}{2}\left\{z - 1 - (z+1)\sqrt{1-\frac{4}{z}}\right\}. \tag{5}$$

From the theory of distribution functions (see Chihara [1]), we have Stieltjes inversion function

$$\psi(t) - \psi(s) = -\frac{1}{\pi}\int_s^t \Im F(x+iy)dx. \tag{6}$$

Since $F(\bar{z}) = \overline{F(z)}$, it can be written in the form

$$\psi(t) - \psi(0) = -\frac{1}{2\pi i}\lim_{y\to 0^+}\int_0^t \Big[F(x+iy) - F(x-iy)\Big]dx. \tag{7}$$

Knowing that

$$\int_0^t F(x+a)dx = \frac{1}{4}\left\{a^2\ \sqrt{1-\frac{4}{a}} - 2t + 2at + t^2 - (a+t)^2\sqrt{1-\frac{4}{a+t}}\right\}$$
$$-2\log\Big(-2+a+a\ \sqrt{1-\frac{4}{a}}\Big) + 2\log\Big(-2+a+t+(a+t)\ \sqrt{1-\frac{4}{a+t}}\Big),$$

we find the distribution function

$$\psi(t)=\begin{cases}\frac{1}{4\pi}\left\{t\,\sqrt{t(4-t)}-8\Big(\pi-\arctan\frac{\sqrt{(4-t)t}}{2-t}\Big)\right\}, & 0\le t<2;\\ \frac{1}{4\pi}\left\{t\,\sqrt{t(4-t)}-8\arctan\frac{\sqrt{(4-t)t}}{t-2}\right\}; & 2\le t\le 4.\end{cases}$$

After differentiation of $\psi(t)$ and simplification of the resulting expression, we finally have:

$$w(x)=\frac{1}{2}(x+1)\sqrt{\frac{4}{x}-1},\quad x\in(0,4). \tag{8}$$

In this way, we obtained the positive-definite L that satisfies (4) and proved that the corresponding orthogonal polynomial sequence exists. We have

Theorem 1. *The monic polynomial sequence $\{P_n(x)\}$ orthogonal with respect to the linear functional*

$$L(f):=\frac{1}{2\pi}\int_0^4 f(x)(x+1)\sqrt{\frac{4}{x}-1}dx, \tag{9}$$

satisfies the three-term recurrence relation

$$P_{n+1}(x)=(x-\alpha_n)P_n(x)-\beta_n P_{n-1}(x), \tag{10}$$

with

$$\alpha_n=2-\frac{1}{F_{2n+1}F_{2n+3}},\quad \beta_n=1+\frac{1}{F_{2n+1}^2},\qquad k\ge 0 \tag{11}$$

where F_i is the i-th Fibonacci number.

Example 1. The first members of this sequence are:

$$\begin{aligned}P_0(x) &= 1;\\ P_1(x) &= x-\frac{3}{2};\\ P_2(x) &= x^2-\frac{17}{5}x+\frac{8}{5};\\ P_3(x) &= x^3-\frac{70}{13}x^2+\frac{95}{13}x-\frac{21}{13};\\ P_4(x) &= x^4-\frac{251}{34}x^3+\frac{290}{17}x^2-\frac{435}{34}x+\frac{55}{34}.\end{aligned}$$

Notice that $P_n(0)=(-1)^n F_{2n+2}/F_{2n+1}$.

Proof of Theorem 1. Denoting by $W_n(x)=P_n^{(1/2,-1/2)}(x)$ $(n\ge 0)$ a special Jacobi polynomial, which is also known as *the Chebyshev polynomial of the fourth kind*.

The sequence of these polynomials is orthogonal with respect to $p^{(1/2,-1/2)}(x)=(1-x)^{1/2}(1+x)^{-1/2}$ on the interval $(-1,1)$. These polynomials can be expressed

(Szegö [9]) by

$$W_n(\cos\theta) = \frac{\sin(n+\frac{1}{2})\theta}{2^n \sin\frac{1}{2}\theta}.$$

and satisfy the three-term recurrence relation (Chihara [1]):

$$W_{n+1}(x) = (x-\alpha_n^*)\, W_n(x) - \beta_n^* W_{n-1}(x) \quad (n=0,1,\ldots),$$
$$W_{-1}(x) = 0, \quad W_0(x) = 1,$$

where

$$\alpha_0^* = -\frac{1}{2}, \quad \alpha_n^* = 0, \qquad \beta_0^* = \pi, \quad \beta_n^* = \frac{1}{4} \qquad (n \geq 1).$$

If we use the weight function $\hat{p}(t) = (t-c)p^{(1/2,-1/2)}(t)$, then the corresponding coefficients $\hat{\alpha}_n$ and $\hat{\beta}_n$ can be evaluated as follows (see, for example, Gautschi [2])

$$\hat{\alpha}_n = c - \frac{W_{n+1}(c)}{W_n(c)} - \beta_{n+1}^* \frac{W_n(c)}{W_{n+1}(c)}, \tag{12}$$

$$\hat{\beta}_n = \beta_n^* \frac{W_{n-1}(c) W_{n+1}(c)}{W_n^2(c)}, \quad n \in \mathbb{N}. \tag{13}$$

Here, we use $c = -3/2$ and $\hat{p}(x) = (x+3/2)(1-x)^{1/2}(1+x)^{-1/2}$.

If we write $\lambda_n = W_n(-3/2)$ then, using the three-term recurrence relation for $W_n(x)$, we have

$$4\lambda_{n+1} + 6\lambda_n + \lambda_{n-1} = 0,$$

with initial values $\lambda_0 = 1, \quad \lambda_1 = -1$.

So, we find

$$\lambda_n = W_n(-3/2) = \frac{(-1)^n}{2\sqrt{5}\ 4^n}\left\{(\sqrt{5}+1)(3+\sqrt{5})^n + (\sqrt{5}-1)(3-\sqrt{5})^n\right\}.$$

Denoting by

$$\phi = \frac{1+\sqrt{5}}{2}, \qquad \overline{\phi} = \frac{1-\sqrt{5}}{2} \tag{14}$$

the golden section numbers, we can write:

$$\lambda_n = W_n(-3/2) = \frac{(-1)^n}{\sqrt{5}\ 2^n}(\phi^{2n+1} - \overline{\phi}^{2n+1}) = \frac{(-1)^n}{2^n} F_{2n+1}. \tag{15}$$

In order to simplify further algebraic manipulations we shall use

$$F_{2n-1}F_{2n+3} = F_{2n+1}^2 + 1 \tag{16}$$

This formula is a special case of the identity (Vajda [12]):

$$G(n+i)H(n+k) - G(n)H(n+i-k) = (-1)^n(G(i)H(k) - G(0)H(i+k)) \tag{17}$$

where G and H are sequences that satisfy the same recurrence relation as the Fibonacci numbers with possibly different initial conditions. However, we take both G and H to be the Fibonacci numbers and $n \to 2n+1$, $i = 2, k = -2$.

Now

$$\begin{aligned}\hat{\beta}_n &= \frac{1}{4}\frac{\lambda_{n-1}\lambda_{n+1}}{\lambda_n^2} = \frac{1}{4}\frac{F_{2n-1}F_{2n+3}}{F_{2n+1}^2} \\ &= \frac{1}{4}\left\{1+\frac{1}{F_{2n+1}^2}\right\} \end{aligned} \tag{18}$$

and

$$\begin{aligned}\hat{\alpha}_n &= -\frac{3}{2} - \frac{\lambda_{n+1}}{\lambda_n} - \frac{1}{4}\frac{\lambda_n}{\lambda_{n+1}} \\ &= \frac{-3F_{2n+1}F_{2n+3} + F_{2n+3}^2 + F_{2n+1}^2}{2F_{2n+1}F_{2n+3}} \\ &= \frac{F_{2n+2}^2 - F_{2n+1}F_{2n+3}}{2F_{2n+1}F_{2n+3}} \\ &= -\frac{1}{2F_{2n+1}F_{2n+3}}. \end{aligned}$$

If a new weight function $p(x)$ is introduced by

$$p(x) = \hat{p}(ax+b)$$

then we have

$$\alpha_n = \frac{\hat{\alpha}_n - b}{a}, \qquad \beta_n = \frac{\hat{\beta}_n}{a^2} \qquad (n \geq 0).$$

Now, by using $x \mapsto x/2 - 1$, i.e., $a = 1/2$ and $b = -1$, we have the wanted weight function

$$w(x) = \hat{p}(\frac{x}{2} - 1) = \frac{1}{2}(x+1)\sqrt{\frac{4-x}{x}}.$$

Thus

$$\alpha_n = 2 - \frac{5}{(\phi^{2n+1} - \overline{\phi}^{2n+1})(\phi^{2n+3} - \overline{\phi}^{2n+3})} = 2 - \frac{1}{F_{2n+1}F_{2n+3}} \tag{19}$$

and

$$\beta_n = 1 + \frac{5}{(\phi^{2n+1} - \overline{\phi}^{2n+1})^2} = 1 + \frac{1}{F_{2n+1}^2} \tag{20}$$

finishing the proof of (1) .□

3. Layman's conjecture

By making use of (2) we have that:

$$h_n = a_0^n \left(1+\frac{1}{F_3^2}\right)^{n-1}\left(1+\frac{1}{F_5^2}\right)^{n-2}\cdots\left(1+\frac{1}{F_{2n-1}^2}\right) \tag{21}$$

Using (16) we can write (21) as:

$$h_n = a_0^n \left(\frac{F_1 F_5}{F_3^2}\right)^{n-1} \left(\frac{F_3 F_7}{F_5^2}\right)^{n-2} \left(\frac{F_5 F_9}{F_7^2}\right)^{n-3} \cdots \frac{F_{2n-3} F_{2n+1}}{F_{2n-1}^2} \tag{22}$$

Since $a_0 = 2 = F_3$ the corresponding factors cancel, therefore:

$$h_n = F_{2n+1} \qquad (n \geq 0),$$

thus proving that Hankel transform of A005807 equals A001519 -sequence of Fibonacci numbers with odd indices.

As we have mentioned in the introduction, Layman observed that the Hankel transform of A005807 equals A001906 -sequence of Fibonacci numbers with even indices. This sequence is obtained if we start the Hankel matrix from $a_1 = 3$, i.e., determinants will have a_1 on the position $(1, 1)$.

The proof of this fact is almost identical with the proof presented here, and so we do not include it. Notice that now we construct $L[x^n] = a_{n+1}$ and that $a_1 = 3 = F_4$; in (17) we take $n \to 2n$. We also use the easily provable fact $P_n(0) = (-1)^n F_{2n+2}/F_{2n+1}$ (see Example 1).

Finally we mention that, following Layman [5], it is known that the Hankel transform is invariant with the respect to the Binomial and Invert transform, so all the sequences obtained from A005807 using these two transformations have the Hankel transform shown here.

robbins@math.sfsu.edu

Abstract

Let n, r be natural numbers, with $r \geq 2$. We present convolution-type formulas for the number of partitions of n that are (1) not divisible by r; (2) coprime to r. Another result obtained is a formula for the sum of the odd divisors of n.

1 Introduction

We derive several convolution-type identities linking partition functions to divisor sums, thereby extending some prior results. In addition, we obtain a Lambert series-like identity for sums of odd divisors.

2 Preliminaries

Let $A \subset N$, the set of all natural numbers. Let n, m, $r \in N$ with $r \geq 2$, $m \geq 2$, m squarefree. Let $x \in C$, $|x| < 1$.

Definition 1 Let $p_A(n)$ denote the number of partitions of n into parts that belong to A.

Definition 2 Let $\sigma_A(n)$ denote the sum of the divisors, d , of n such that $d \in A$.

Definition 3 Let $p(n)$ denote the number of partitions of n.

Definition 4 Let $q(n)$ denote the number of partitions of n into distinct parts (or into odd parts).

Definition 5 Let $q_0(n)$ denote the number of partitions of n into distinct odd parts (the number of self-conjugate partitions of n).

Definition 6 Let $b_r(n)$ denote the number of *r-regular* partitions of n (the number of partitions of n such that no part is a multiple of r or such that no part occurs r or more times).

Remark: Note that $b_2(n) = q(n)$.

Definition 7 Let $f_m(n)$ denote the number of partitions of n such that all parts are coprime to m.

Definition 8 Let $\sigma_r(n)$ denote the sum of the divisors, d , of n such that d does not divide r.

Definition 9 Let $\sigma^*_m(n)$ denote the sum of the divisors, d , of n such that d is coprime to m.

Definition 10 Let $\phi(n)$ denote Euler's totient function.

Remark: If p is prime, then $f_p(n) = b_p(n)$ and $\sigma^*_p(n) = \sigma_p(n)$.

$$\sum_{n=0}^{\infty} q(n)x^n = \prod_{n=1}^{\infty}(1 + x^n) \tag{1}$$

Proposition 1 Let $f : A \to N$ be a function such that

$$F_A(x) = \prod_{n\in A}(1 - x^n)^{-f(n)/n} = 1 + \sum_{n=1}^{\infty} p_{A,f}(n)x^n$$

and

$$G_A(x) = \sum_{n\in A} \frac{f(n)}{n} x^n$$

converge absolutely and represent analytic functions in the unit disc: $|x| < 1$. Let $p_{A,f}(0) = 1$ and

$$f_A(k) = \sum\{f(d) : d|k,\, d \in A\} \quad .$$

Then

$$np_{A,f}(n) = \sum_{k=1}^{n} p_{A,f}(n - k)f_A(k) \quad .$$

Remarks: Proposition 1 is Theorem 14.8 in [1]. If we let $A = N$, $f(n) = n$, then we obtain

$$np(n) = \sum_{k=1}^{n} p(n-k)\sigma(k) \quad .$$

(See [1, p. 323]). If we let $A = N - 2N$ (the set of odd natural numbers) and $f(n) = n$, we obtain

$$nq(n) = \sum_{k=1}^{n} q(n-k)\sigma_2(k) \quad . \tag{2}$$

This is given as Theorem 1 in [2], and is a special case of Theorem 1(a) below.

3 The Main Results

Theorem 1

$$nb_r(n) = \sum_{k=1}^{n} b_r(n-k)\sigma_r(k) \tag{3}$$

$$nf_m(n) = \sum_{k=1}^{n} f_m(n-k)\sigma_m^*(k) \tag{4}$$

Proof: We apply Proposition 1 with $f(n) = n$. If we let $A = N - rN$ (the set of natural numbers not divisible by r) then (3) follows. If we let $A = \{n \in N : (m,n) = 1\}$, then (4) follows. ∎

Next, we present a theorem regarding odd divisors of n.

Theorem 2 Let $f : N \to N$ be a multiplicative function. Let $n = 2^k m$, where $k \geq 0$ and m is odd. Then

$$\sum_{d|n}(-1)^{d-1} f(\frac{n}{d}) = \{f(2^k) - \sum_{j=0}^{k-1} f(2^j)\} \sum_{d|n\,,\,2\not|d} f(d) \quad . \tag{5}$$

Proof: If $d|n$, then by hypothesis, $d = 2^i r$ where $0 \leq i \leq k$, $r|m$. Now

$$\sum_{d|n}(-1)^{d-1} f(\frac{n}{d}) = \sum_{d|n\,,\,2\not|d} f(\frac{n}{d}) - \sum_{2|d|n} f(\frac{n}{d})$$

$$= \sum_{r|m} f(2^k m/r) - \sum_{r|m}\sum_{i=1}^{k} f(2^{k-i}m/r) = f(2^k)\sum_{r|m} f(r) - \sum_{i=1}^{k} f(2^{k-i})\sum_{r|m} f(r)$$

$$= \{f(2^k) - \sum_{i=1}^{k} f(2^{k-i})\} \sum_{r|m} f(r) = \{f(2^k) - \sum_{j=0}^{k-1} f(2^j)\} \sum_{d|n\,,\,2\not|d} f(d) \quad . \quad \blacksquare$$

Corollary 1

$$\sum_{d|n} (-1)^{d-1} \frac{n}{d} = \sum_{d|n\,,\,2\not|d} d \tag{6}$$

$$\sum_{d|n} (-1)^{d-1} \phi(\frac{n}{d}) = 0 \tag{7}$$

Proof: If f is multiplicative and $n = 2^k m$, where $k \geq 0$ and m is odd, let

$$g(f,k) = \{f(2^k) - \sum_{j=0}^{k-1} f(2^j)\}$$

Theorem 2 may be written as:

$$\sum_{d|n} (-1)^{d-1} f(\frac{n}{d}) = g(f,k) \sum_{d|n\,,\,2\not|d} f(d) \tag{8}$$

Now each of the functions: $f(n) = n$, $f(n) = \phi(n)$ is multiplicative, so Theorem 1 applies. Furthermore,

$$g(n,k) = 2^k - \sum_{j=0}^{k-1} 2^j = 1 \tag{9}$$

$$g(\phi(n),k) = \phi(2^k) - \sum_{j=0}^{k-1} \phi(2^j) = 0 \tag{10}$$

We see that (6) follows from (8) and (9), and (7) follows from (8) and (10). $\blacksquare$

Theorem 3

$$\sum_{n=1}^{\infty} \sigma_2(n) x^n = \sum_{n=1}^{\infty} \frac{n x^n}{1 + x^n}$$

First Proof:

$$\sum_{m=1}^{\infty} \frac{m x^m}{1 + x^m} = \sum_{m,k=1}^{\infty} (-1)^{k-1} m x^{km}$$

$$= \sum_{n=1}^{\infty} x^n (\sum_{d|n} (-1)^{d-1} \frac{n}{d} = \sum_{n=1}^{\infty} \sigma_2(n) x^n$$

by (6) . ■

Second Proof: (2) implies

$$\sum_{n=0}^{\infty} (\sum_{k=0}^{n} q(n-k)\sigma_2(k)) x^n = \sum_{n=0}^{\infty} nq(n) x^n$$

so that

$$(\sum_{n=0}^{\infty} q(n)x^n)(\sum_{n=0}^{\infty} \sigma_2(n)x^n) = \sum_{n=0}^{\infty} nq(n)x^n \tag{11}$$

Now (1) implies

$$\frac{d}{dx}(\sum_{n=0}^{\infty} q(n)x^n) = \frac{d}{dx}(\prod_{n=1}^{\infty}(1+x^n))$$

that is,

$$\sum_{n=1}^{\infty} nq(n)x^{n-1} = \sum_{n=1}^{\infty} nx^{n-1} \prod_{m \neq n} (1+x^m)$$

hence

$$\sum_{n=0}^{\infty} nq(n)x^n = \sum_{n=0}^{\infty} \frac{nx^n}{1+x^n} \prod_{n=1}^{\infty}(1+x^n)$$

$$= \sum_{n=0}^{\infty} \frac{nx^n}{1+x^n} \sum_{n=0}^{\infty} q(n)x^n$$

by (1). The conclusion now follows from (11) . ■

Remarks: Theorem 3 may be compared to the well-known Lambert series identity:

$$\sum_{n=1}^{\infty} \sigma(n)x^n = \sum_{n=1}^{\infty} \frac{nx^n}{1-x^n}$$

In [2], Theorem 2, part (b), we obtained an explicit formula for $\sigma_2(n)$ in terms of $q(n)$ and $q_0(n)$, namely:

$$\sigma_2(n) = \sum_{k=1}^{n} (-1)^{k-1} k q_0(k) q(n-k)$$

zsunik@math.unl.edu

Abstract

We introduce a transformation on integer sequences for which the set of images is in bijective correspondence with the set of Young tableaux. We use this correspondence to show that the set of images, known as ballot sequences, is also the set of double points of our transformation.

In the second part, we introduce other transformations of integer sequences and show that, starting from any sequence, repeated applications of the transformations eventually produce a fixed point (a self-describing sequence) or a double point (a pair of mutually describing sequences).

Counting equal terms

Let $\mathcal{A}^+$ be the set of finite integer sequences $a = a_1a_2\dots$ with $1 \leq a_i \leq i$, for all indices. Define a transformation of sequences $\beta : \mathcal{A}^+ \to \mathcal{A}^+$ by

$$\beta(a)_i = \#\{j \mid j \leq i,\ a_j = a_i\}.$$

Thus $\beta(a)_i$ counts the number of terms in the sequence a that are equal to a_i and appear in the initial segment of a consisting of the first i positions. Therefore, in some sense, the sequence $\beta(a)$ describes the sequence a. It is easy to see that the only fixed point of β is the sequence 1. However, there are many double points, i.e., sequences a for which $\beta^2(a) = a$. If a is a double point so is $b = \beta(a)$, we have $a = \beta(b)$, and the sequences a and b mutually describe each other.

Theorem 1. *The set of double points of β of length n in $\mathcal{A}^+$*

- *corresponds bijectively to the set of Young tableaux of size n.*
- *is the set of images of the sequences of length n under β.*
- *is the set of ballot sequences of length n, i.e., sequences a of length n such that, for every initial segment a' of a and every positive integer x, the number of occurrences of the term x in a' is no smaller than the number of occurrences of $x+1$.*

By Young tableau of size n we mean a standard Young tableau, i.e., a left justified arrangement of the integers $1, 2, \ldots, n$ in several rows of non-increasing length such that all rows and columns have increasing terms (see [Sag90]). For example,

$$\begin{array}{cccccc} 1 & 2 & 5 & 8 & 10 & 12 \\ 3 & 6 & 7 & & & \\ 4 & 9 & 11 & & & \\ 13 & & & & & \end{array} \tag{1}$$

is a Young tableau of size 13. Denote by $\mathcal{Y}_n$ the set of Young tableaux of size n and by $\mathcal{B}_n$ the set of ballot sequences of length n.

We first remind the reader of a known bijective correspondence between $\mathcal{Y}_n$ and $\mathcal{B}_n$ (see [Sag01, page 176]). For a tableau t in $\mathcal{Y}_n$ define a sequence $\sigma(t)$ of length n by

$$\sigma(t)_i = \text{the number of the row in which } i \text{ appears in } t.$$

In other words, the entries in the first row of t point to the positions in the sequence $\sigma(t)$ whose value is 1, the entries in the second row point to the positions in $\sigma(t)$ whose value is 2, etc. In the other direction, for a sequence $a = a_1 a_2 \ldots a_n$ in $\mathcal{B}_n$ define a tableau $\sigma'(a)$ by

$$\sigma'(a)_{i,j} = \text{the position number of the } j\text{-th occurrence of } i \text{ in } a.$$

Therefore, the first row of $\sigma'(a)$ consists of pointers, in increasing order, to the positions in the sequence a whose value is 1, the second row consists of pointers, in increasing order, to the positions whose value is 2, etc.

It is easy to see that, for every Young tableau t in $\mathcal{Y}_n$ and every ballot sequence a in $\mathcal{B}_n$, $\sigma(t)$ is a ballot sequence, $\sigma'(a)$ is a Young tableau, and $\sigma : \mathcal{Y}_n \to \mathcal{B}_n$ and $\sigma' : \mathcal{B}_n \to \mathcal{Y}_n$ are mutually inverse bijections.

For example, the table below gives the ballot sequence $a = \sigma(t)$ that corresponds to the Young tableau t in (1).

i	1	2	3	4	5	6	7	8	9	10	11	12	13
$\sigma(t)_i$	1	1	2	3	1	2	2	1	3	1	3	1	4

Lemma 1. *The restrictions of β and $\sigma\tau\sigma'$ to the set $\mathcal{B}_n$ of ballot sequences of length n are equal, where τ is transposition of tableaux.*

Proof. Let $a = a_1 a_2 \ldots a_m \ldots a_n$ be a sequence in $\mathcal{B}_n$ and let $a_m = i$ be the j-th occurrence of i in a. By definition,

$$\beta(a)_m = j.$$

On the other hand, $\sigma'(a)_{i,j} = m$, the transposition then gives $\tau\sigma'(a)_{j,i} = m$ and therefore

$$\sigma\tau\sigma'(a)_m = j.$$

□

Since τ acts as an involution on $\mathcal{Y}_n$, β acts as an involution on $\mathcal{B}_n$. Therefore, all ballot sequences are double points of β. This also shows that all ballot sequences are images under β. To prove Theorem 1 it remains to show that all images under β are ballot sequences. This is rather obvious. Indeed, the x-th occurrence of any term in a happens to the left of its $(x+1)$-th occurrence. Thus, in every prefix of b the number of occurrences of x is no smaller than the number of occurrences of $x+1$.

Other counts

For the other transformations we have in mind it is more pleasant to work with slightly different sequences than before. Let $\mathcal{A}$ be the set of all finite integer sequences $a = a_0a_1a_2\ldots$ with $0 \le a_i \le i$, for all indices, and define $\mathcal{A}_n$ to be the set of sequences $a = a_0a_1a_2\ldots a_n$ of length $n+1$ in $\mathcal{A}$.

Theorem 2. *Consider the following six transformations of sequences in $\mathcal{A}$, given by*

$$\begin{aligned}
\alpha_{eq}(a)_i &= \#\{j \mid j < i,\ a_j = a_i\},\\
\alpha_{neq}(a)_i &= \#\{j \mid j < i,\ a_j \neq a_i\},\\
\alpha_{geq}(a)_i &= \#\{j \mid j < i,\ a_j \geq a_i\},\\
\alpha_{l}(a)_i &= \#\{j \mid j < i,\ a_j < a_i\},\\
\alpha_{leq}(a)_i &= \#\{j \mid j < i,\ a_j \leq a_i\},\\
\alpha_{g}(a)_i &= \#\{j \mid j < i,\ a_j > a_i\}.
\end{aligned}$$

Starting from any sequence in $\mathcal{A}$, each of these transformations reaches a fixed or a double point after finitely many applications of the transformation. The following table gives the type of points that are reached, their number in $\mathcal{A}_n$ and a rough estimate of the number of steps needed to reach such a point.

	type of points	*number of points*	*steps needed*
α_{eq}	*double*	$(n+1)$*-th Young number*	*1*
α_{neq}	*fixed*	2^n	$O(n^2)$
α_{geq}	*double*	*unknown, at least* 2^n	$O(n^2)$
α_{l}	*fixed*	$(n+1)$*-th Catalan number*	$O(n^2)$
α_{leq}	*fixed*	*unique fixed point* $012\ldots n$	$O(n^2)$
α_{g}	*fixed*	*unique fixed point* $000\ldots0$	$O(n)$

The two transformations that have double points have the sequence 0 *as their unique fixed point (which is counted as one double point).*

The proof is divided in six parts corresponding to the six transformations.

Properties of α_{eq}. The assertions about α_{eq} follow from Theorem 1. Indeed, the transformations α_{eq} and β are conjugated by the bijection from $\mathcal{A}$ to $\mathcal{A}^+$ that adds 1 to each term of the sequences in $\mathcal{A}$. □

Properties of α_{neq}. We claim that the set of fixed points of α_{neq} in $\mathcal{A}_n$ is the set $\mathcal{H}_n$ that consist of the 2^n sequences $a = a_0a_1 \dots a_n$ with $a_i = i$ or $a_i = a_{i-1}$, for $i = 1, \dots, n$.

The set of sequences in $\mathcal{A}_n$ can be ordered lexicographically. Namely, for $a = a_0a_1 \dots a_n$ and $b = b_0b_1 \dots b_n$, set $a < b$ if $a_i < b_i$ at the first index where a and b differ.

The statement of the theorem then follows from the fact that $\alpha_{neq}(a) = a$, for a in $\mathcal{H}_n$, and $\alpha_{neq}(a) > a$, for sequences a outside of $\mathcal{H}_n$. The proof is done by induction on n.

The claims are easily verified for $n = 0$ and $n = 1$. Assume that the claims are true for some $n \geq 1$.

Let

$$a = a_0a_1 \dots a_nx$$

be a sequence in $\mathcal{H}_{n+1}$. We consider two cases.

If $x = n + 1$ then

$$\#\{j \mid j < n + 1,\ a_j \neq x\} = \#\{j \mid j < n + 1,\ a_j \neq n + 1\} = n + 1 = x.$$

If $a_n = x$ then

$$\#\{j \mid j < n + 1,\ a_j \neq x\} = \#\{j \mid j < n,\ a_j < a_n\} = a_n = x,$$

where the first equality comes from the fact that $a_n = x$ and the second from the inductive assumption.

Thus all sequences in $\mathcal{H}_n$ are fixed under α_{neq}, for all n.

Now, let

$$a = a_0a_1 \dots a_nx$$

be a sequence in $\mathcal{A}_{n+1}$ that is not in $\mathcal{H}_{n+1}$. If the proper initial segment

$$a' = a_0a_1 \dots a_n$$

is not fixed by α_{neq} we obtain the claim directly by the inductive assumption. So let us assume that a' is in $\mathcal{H}_n$ but a is not in $\mathcal{H}_{n+1}$.

We have

$$\#\{j \mid j < n + 1,\ a_j \neq x\} = \#\{j \mid j < n,\ a_j \neq x\} + 1 \geq x + 1,$$

where the equality comes from the fact that $a_n \neq x$ and the inequality follows from the inductive assumption. Note that we could use the inductive assumption because $x \neq n + 1$ and therefore the sequence

$$a'' = a_0a_1 \dots a_{n-1}x$$

is in $\mathcal{A}_n$.

Thus, for all n and sequences a in $\mathcal{A}_n$ but not in $\mathcal{H}_n$, $\alpha_{neq}(a) > a$. □

Properties of α_{geq}. Define an *extreme sequence* in $\mathcal{A}_n$ to be a sequence $a = a_0a_1 \dots a_n$ such that, for all indices, $a_i = 0$ or $a_i = i$. There are 2^n extreme sequences in $\mathcal{A}_n$ and they are all double points of α_{geq}.

We prove by induction on n that repeated applications of α_{geq} to the sequences in $\mathcal{A}_n$ eventually produce double points.

The statement is true for $n = 0$ and $n = 1$.

Assume that the statement is true for all sequences in $\mathcal{A}_n$.

Let

$$a = a_0a_1 \dots a_nx$$

be a sequence in $\mathcal{A}_{n+1}$. By the inductive hypothesis, we may assume that the initial segment (prefix) $a_0a_1 \dots a_n$ is already a double point of α_{geq}. Starting with the sequence a, we apply α_{geq}, α_{geq}^2 and α_{geq}^3, etc., and obtain consecutively the sequences

$$\begin{gathered} a_0a_1 \dots a_nx \\ b_0b_1 \dots b_ny \\ a_0a_1 \dots a_nx' \\ b_0b_1 \dots b_ny' \\ a_0a_1 \dots a_nx'' \\ \dots \end{gathered}$$

If $x' \geq x$ then

$$\{j \mid j < n+1,\ a_j \geq x'\} \subseteq \{j < n+1 \mid a_j \geq x\}$$

and therefore

$$y' = \#\{j \mid j < n+1,\ a_j \geq x'\} \leq \#\{j \mid j < n+1,\ a_j \geq x\} = y.$$

By reversing the inequalities (including $\subseteq$) we also obtain that

$$x' \leq x \qquad \text{implies} \qquad y' \geq y.$$

Therefore, the infinite sequence $x, x', x'', \dots$ is either non-increasing or non-decreasing and since it takes values in the finite range between 0 and $n+1$ it must stabilize after no more than $n+1$ steps. □

Properties of α_l. This is proved in [Šun02]. All fixed points of α_l can be organized in a certain rooted labelled tree (called Catalan family tree) and the results follow from there. □

Properties of α_{leq}. If $012 \dots nx$ is a sequence with $x \neq n+1$ then $\alpha_{leq}(012 \dots nx) = 012 \dots ny$, where $y = x + 1$. □

Properties of α_g. If $0 \dots 0x$ is a sequence with $x \neq 0$ then $\alpha_g(0 \dots 0x) = 0 \dots 00$. □

As an example, we list the 10 double points of α_{geq} in $\mathcal{A}_3$, namely the four extreme pairs

$$0000 \leftrightarrow 0123, \quad 0003 \leftrightarrow 0120, \quad 0020 \leftrightarrow 0103, \quad 0023 \leftrightarrow 0100$$

and the only additional pair

$$0021 \leftrightarrow 0101.$$

One can verify directly that the sequence that counts the number of double points of α_{geq} in $\mathcal{A}_n$ starts as follows

$$1, 2, 4, 10, 26, 70, 216, \ldots$$

This sequence (actually only the first several terms) was submitted by the author to the On-Line Encyclopedia of Integer Sequences [Slo] on 06/24/2002 and it appears there as the sequence A071962. It is a new sequence that could not be found in the Encyclopedia before.

Concluding remarks

We note that the six transformations we defined are actually three pairs of transformations related by the *mirror involution* of $\mathcal{A}$, given by

$$\mu(a)_i = i - a_i.$$

Indeed, $\alpha_{eq} = \mu\alpha_{neq}$, $\alpha_{geq} = \mu\alpha_l$ and $\alpha_{leq} = \mu\alpha_g$. However, we did not use this fact in our considerations. In particular, we did not find a way to use it in order to count the double points of α_{geq} by relating them somehow to the fixed points of α_l counted by the Catalan numbers (see [Šun02]).

It was observed by Louis Shapiro that the Catalan numbers, the Young numbers and the powers of 2 count certain card shuffles in the paper by Robbins and Boelker [RB81], but the author could not find a connection to the periodic points of the sequence transformations introduced here.

One can easily define other sequence transformations that lead to periodic points (one rather general way of producing such is by using tree endomorphisms, as noted in [Šun02]). Apart from a precise description and enumeration of the periodic points, one may also try to describe and enumerate the sequences on the other side of the spectrum, namely the sequences that require maximal number of steps before a periodic point is reached.

Acknowledgments

Thanks to Richard Stanley and Louis Shapiro for their interest and input. Thanks to the referee for the suggested improvements of the text.

Abstract

A general pattern inventory is given for a direct enumeration of chiral and achiral graphs of any polyheterosubstituted monocyclic cycloalkane with an empirical formula $C_nX_{m_1}....Y_{m_i}...Z_{m_k}$ *satisfying the condition* $m_1+...+m_i+...+m_k=2n.$ *(1)*

1. INTRODUCTION

The application of different enumeration tools to numerous problems of chemistry is an attractive point for mathematicians and chemists. The abundant chemistry literature on this subject deals with Pólya's counting theorem[1,2] in the series of acyclic organic molecules and among the articles published in this field, one may retain the contribution of Balasubramanian[3,4] who has presented the generalized wreath product method for the enumeration of stereo and position isomers of polysubstituted organic compounds and later explored the applications of combinatorics and graph theory to spectroscopy and quantum chemistry. The idea to calculate the sequences of exact numbers of chiral and achiral skeletons for any molecule of the series of homopolysubstituted monocyclic cycloalkanes $C_nH_{2n-m}X_m$, (X being a non isomerisable substituent), has been discussed by Nemba and Ngouhouo [5], Nemba[6], Nemba and Fah [7], Nemba and Balaban [8].

Our purpose in this study is to present a quick algorithm for direct enumeration of chiral and achiral graphs of stereo and position isomers of any polyheterosubstituted monocyclic cycloalkane with an empirical formula, $C_n X_{m_1} ....Y_{m_i} ...Z_{m_k}$ having (k+1)-tuples of positive integers $(n\ , m_1,...,m_i,...,m_k)$ which satisfy equation 1 and denote respectively the ring size and the numbers of non isomerisable substituents of types X…,Y,…and Z. As indicated in a previous study, we assume ring flip to be fast enough to equilibrate conformers [8].

2. FORMULATION OF THE ALGORITHM

Let us note the system $C_n X_{m_1} ....Y_{m_i} ...Z_{m_k} = (n\ , m_1,...,m_i,...,m_k)$ and consider as shown in figure-1 the stereograph in D_{nh} symmetry of its parent monocyclic cycloalkane $C_n H_{2n}$. This tridimensional graph contains *2n* substitution sites labelled $1,2,...,i,...,n$ and $1',2',...,i',...,n'$. Define the set of divisors D_{2n} or D_n for *2n* and *n* if n odd or even respectively. Then derive the set P of permutations induced by the 4n symmetry operations of D_{nh}. It must be recalled that the chemistry specific notation D_{nh} refers to a point group containing 4n symmetry elements which are for *n* odd :

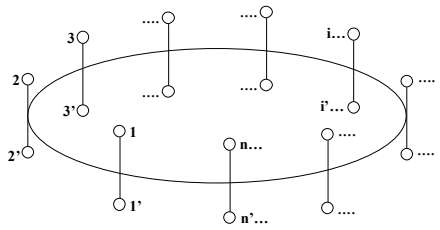
$E,\ nC_2,\ \sigma_h,\ n\sigma_v,\ C_n^r$ with $1 \le r(\text{odd or even}) \le n\text{-}1,\ S_n^{r'}$ with $1 \le r'(\text{odd}) \le 2n\text{-}1,$

and for *n* even :

$E,\ C_2,\ \sigma_h,\ i,\ \frac{n}{2}C_2^{/},\ \frac{n}{2}C_2^{//},\ \frac{n}{2}\sigma_v,\ \frac{n}{2}\sigma_d,\ C_n^r$ with $1 \le r(\text{odd or even and} \ne \frac{n}{2}) \le n\text{-}1,$

$S_n^{r'}$ with $1 \le r'(\text{odd and} \ne \frac{n}{2}) \le n\text{-}1.$

Figure 1. Stereograph in D_{nh} symmetry of its parent monocyclic cycloalkane $C_n H_{2n}$.



$$P = \left\{ a_1\left[1^{2n}\right], (n+1)\left[2^n\right], ..., a_d\left[d^{\frac{2n}{d}}\right], ..., a_n\left[n^2\right], a_{2n}\left[2n\right], n\left[1^2 2^{n-1}\right] \right\} \quad n \text{ odd,} \quad (2)$$

$$P = \left\{ a_1\left[1^{2n}\right], \frac{3}{2}(n+2)\left[2^n\right], ..., a_d\left[d^{\frac{2n}{d}}\right], ..., a_n\left[n^2\right], \frac{n}{2}\left[1^4 2^{n-2}\right] \right\} \quad n \text{ even.} \quad (3)$$

Eliminate in P the contributions of reflections and rotoreflections and derive in relations (4)-(5) the set P' of 2n permutations induced by rotation symmetries.

$$P' = \left\{ a_1^{/}\left[1^{2n}\right], n\left[2^{n}\right], \ldots, a_d^{/}\left[d^{\frac{2n}{d}}\right], \ldots, a_n^{/}\left[n^{2}\right] \right\} \quad n \text{ odd,} \qquad (4)$$

$$P' = \left\{ a_1^{/}\left[1^{2n}\right], (n+1)\cdot\left[2^{n}\right], \ldots, a_d^{/}\left[d^{\frac{2n}{d}}\right], \ldots, a_n^{/}\left[n^{2}\right] \right\} \quad n \text{ even.} \qquad (5)$$

The notation $[i^j]$ in expressions (2)-(5) refers to *j* permutation cycles with length *i,* and the coefficients a_d and $a_d^{/}$ are determined from equations (6)-(10) where $\varphi(d)_{rp} = \varphi(d)_{ri}$ and $\varphi(\mu)_{ri}$,

$$a_d = \varphi(d)_{rp} \qquad d(odd), \qquad (6)$$

$$a_{2d} = \varphi(d)_{ri} \qquad d(\text{odd}), \qquad (7)$$

$$a_d = \varphi(d)_{rp} + \varphi(d)_{ri} \quad d(\text{even}) \neq 2\mu \ (\mu \text{ odd}), \qquad (8)$$

$$a_d = \varphi(d)_{rp} + \varphi(d)_{ri} + \varphi(\mu)_{ri} \quad d\ (\text{even}) = 2\mu \ (\mu \text{ odd}), \qquad (9)$$

$$a_d^{/} = \varphi(d)_{rp} \qquad d \text{ odd or even.} \qquad (10)$$

correspond to the Euler totient function for the integer numbers *d* or μ which are the order of proper or improper rotation axes (see indices *rp* or *ri* respectively).

Each permutation resulting from the action of D_{nh} on G induces distinct combinations with repetition (or distinct polyheterosubstitutions) of $(m_1,\ldots,m_i,\ldots,m_k)$ elements of different types X…,Y,… and Z among *2n* substitution sites.

Let $T(a,b,c,\ldots,e,\ldots,f,g) = \dfrac{a!}{b!\,c!\ldots e!\ldots f!\,g!}$ be the multinomial coefficient which corresponds to the number of combinations with repetition of *(b, c,…,e,…,f,g)* objects of kinds X, …,Y,…,Z among $a = 2n$ undistinguishable boxes. Our concern in this step is to derive such numbers resulting from the permutations of types $[d^{\frac{2n}{d}}]$ (with $d \neq 2$), $\left[2^{n}\right]$, $[1^2 2^{n-1}]$ and $[1^4 2^{n-2}]$ listed in P and P'.

a)-If $d_j \in D_c$ is the common divisor of the sequence $(2n\ , m_1,..., m_i,..., m_k)$ for *n* odd or even and $D_c = \{1,..., d_j,...\}$, therefore the number of distinct combinations with repetition or polyheterosubstitutions of $(m_1,..., m_i,..., m_k)$ elements of types X…,Y,… and Z among 2n substitution sites of the stereograph G resulting from the permutation $[d^{\frac{2n}{d}}]$ is given by the multinomial coefficient :

$$T\left(\frac{2n}{d_j}, \frac{m_1}{d_j},..., \frac{m_i}{d_j},..., \frac{m_k}{d_j}\right).$$

b)-In the case of transpositions (2-cycle permutations) noted $[2^n]$ where $d_j = 2$, the result is:

$$T\left(n, \frac{m_1}{2},..., \frac{m_i}{2},..., \frac{m_k}{2}\right).$$

c)-For the permutations of types $[1^2 2^{n-1}]$ or $[1^4 2^{n-2}]$: we simultaneously solve the partition eqs (11) and (12)

$$p_1 + p_2 + ... + p_i + ... + p_k = \begin{cases} 2 & n \quad odd, \\ 4 & n \quad even. \end{cases} \qquad (11)$$

$$m_1^{/} + m_2^{/} + ... + m_i^{/} + ... + m_k^{/} = \begin{cases} n-1 & n \quad odd, \\ n-2 & n \quad even. \end{cases} \qquad (12)$$

to derive the k-tuples of integer numbers $(p_1, p_2..., p_i,..., p_k) \geq 0$ for the choice of the kinds of substituents X,…,Y,… , and Z to be put in 2 or 4 invariant positions and the sequence $(m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/}) \geq 0$ of couples of substituents of the same kind to be placed into n-1 or n-2 boxes. Then check from eq. (13)

$$m_i^{/} = \frac{m_i - p_i}{2} \text{ where } 1 \leq i \leq k, \qquad (13)$$

the compatibility of each couple $(p_i, m_i^{/})$, in the associated sequences $(p_1, p_2..., p_i,..., p_k) \rightarrow (m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/})$.

Let $T(2; p_1, p_2,..., p_i,..., p_k)$ and $T(4; p_1, p_2,..., p_i,..., p_k)$ be the number of ways of putting $(p_1, p_2,..., p_i,..., p_k)$ substituents of k types into 2 or 4 boxes.

Let $T(n-1; m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/})$ and $T(n-2; m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/})$ denote the numbers of placements of $(m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/})$ elements into *n-1* or *n-2* boxes.

Finally, the numbers of combinations with repetition of $(m_1,...,m_i,...,m_k)$ different substituents among *2n* boxes generated by the permutations $\left[1^2 2^{n-1}\right]$ or $\left[1^4 2^{n-2}\right]$ is the sum over λ of the products of multinomial coefficients as given hereafter:

$$\sum_{\lambda} T\left(2; p_1, p_2,..., p_i,..., p_k\right) \cdot T\left(n-1; m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/}\right) \quad n \text{ odd,} \qquad (14)$$

$$\sum_{\lambda} T\left(4; p_1, p_2,..., p_i,..., p_k\right) \cdot T\left(n-2; m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/}\right) \quad n \text{ even,} \qquad (15)$$

and λ indicates the number of compatible solutions $(p_1, p_2..., p_i,..., p_k) \rightarrow \left(m_1^{/}, m_2^{/},..., m_i^{/},..., m_k^{/}\right)$ sorted from eqs (11) and (12).

Finally if we set up the differences *P'-P* and *2P-P'* of the averaged contributions of the 4n and 2n permutations of P and P' one may obtain respectively from eqs (16)-(19) the numbers $A_c(n, m_1,..., m_i,..., m_k)$ of chiral graphs (or enantiomer pairs) and $A_{ac}(n, m_1,..., m_i,..., m_k)$ of achiral forms for any polyheterosubstituted monocyclic system $C_n X_{m_1} ....Y_{m_i} ...Z_{m_k}$.

Hence for *n* odd :

$$A_c(n,m_1,...,m_i,...,m_k) = \frac{1}{4n}\left[\sum_{d_j \neq 2}\left(2a_{d_j}^{/} - a_{d_j}\right)\cdot\begin{pmatrix} \frac{2n}{d_j} \\ \frac{m_1}{d_j},...,\frac{m_i}{d_j},...,\frac{m_k}{d_j}\end{pmatrix} + (n-1)\cdot\begin{pmatrix} n \\ \frac{m_1}{2},...,\frac{m_i}{2},...,\frac{m_k}{2}\end{pmatrix}\right] \qquad (16)$$
$$-\frac{1}{4}\left[\sum_{\lambda}\begin{pmatrix} 2 \\ p_1,...,p_i,...,p_k\end{pmatrix}\cdot\begin{pmatrix} n-1 \\ m_1^{/},...,m_i^{/},...,m_k^{/}\end{pmatrix}\right].$$

$$A_{ac}(n,m_1,...,m_i,...,m_k) = \frac{1}{2n}\left[\sum_{d_j \neq 2}\left(a_{d_j} - a_{d_j}^{/}\right)\cdot\begin{pmatrix} \frac{2n}{d_j} \\ \frac{m_1}{d_j},...,\frac{m_i}{d_j},...,\frac{m_k}{d_j}\end{pmatrix} + \begin{pmatrix} n \\ \frac{m_1}{2},...,\frac{m_i}{2},...,\frac{m_k}{2}\end{pmatrix}\right] \qquad (17)$$
$$+\frac{1}{2}\left[\sum_{\lambda}\begin{pmatrix} 2 \\ p_1,...,p_i,...,p_k\end{pmatrix}\cdot\begin{pmatrix} n-1 \\ m_1^{/},...,m_i^{/},...,m_k^{/}\end{pmatrix}\right].$$

and for *n* even :

$$A_c(n,m_1,...,m_i,...,m_k) = \frac{1}{4n}\left[\sum_{d_j \neq 2}\left(2a_{d_j}^{/} - a_{d_j}\right)\cdot\begin{pmatrix} \frac{2n}{d_j} \\ \frac{m_1}{d_j},...,\frac{m_i}{d_j},...,\frac{m_k}{d_j}\end{pmatrix} + (\frac{n}{2}-1)\cdot\begin{pmatrix} n \\ \frac{m_1}{2},...,\frac{m_i}{2},...,\frac{m_k}{2}\end{pmatrix}\right] \qquad (18)$$
$$-\frac{1}{8}\left[\sum_{\lambda}\begin{pmatrix} 4 \\ p_1,...,p_i,...,p_k\end{pmatrix}\cdot\begin{pmatrix} n-2 \\ m_1^{/},...,m_i^{/},...,m_k^{/}\end{pmatrix}\right].$$

$$A_{ac}(n,m_1,...,m_i,...,m_k) = \frac{1}{2n}\left[\sum_{d_j \neq 2}\left(a_{d_j} - a_{d_j}^{/}\right)\cdot\begin{pmatrix} \frac{2n}{d_j} \\ \frac{m_1}{d_j},...,\frac{m_i}{d_j},...,\frac{m_k}{d_j}\end{pmatrix} + \left(\frac{n}{2}+2\right)\cdot\begin{pmatrix} n \\ \frac{m_1}{2},...,\frac{m_i}{2},...,\frac{m_k}{2}\end{pmatrix}\right] \qquad (19)$$
$$+\frac{1}{4}\left[\sum_{\lambda}\begin{pmatrix} 4 \\ p_1,...,p_i,...,p_k\end{pmatrix}\cdot\begin{pmatrix} n-2 \\ m_1^{/},...,m_i^{/},...,m_k^{/}\end{pmatrix}\right].$$

3. APPLICATIONS

Example 1 : Chiral and achiral graphs of $C_9X_9Y_6Z_3$.

Let $n=9, m_1=9, m_2=6, m_3=3$, $D_{18}=\{1,\ 2,\ 3,\ 6,\ 9,\ 18\}$,

P=$\{[1^{18}],\ 10[2^9],\ 2[3^6],\ 2[6^3],\ 6[9^2],\ 6[18],\ 9[1^2 2^8]\}$ and P'=$\{[1^{18}],\ 9[2^9],\ 2[3^6],\ 6[9^2]\}$. The set of common divisors of the sequence (18,9,6,3) is $D_c=\{1,3\}$, $a_1=a_1'=1$, $a_3=a_3'=2$. The empirical formula contains *k=3* types of substituents. The solutions of the 2 associated partition equations $p_1+p_2+p_3=2$ and $m_1'+m_2'+m_3'=8$ which verify equation (13) are $(p_1,p_2,p_3)=(1,0,1)\rightarrow(m_1',m_2',m_3')=(4,3,1)$. Therefore λ=1 and from equations (16)-(17) one may obtain respectively :

$$A_c(9,9,6,3)=\frac{1}{36}\left[(2-1)\cdot\binom{18}{9,6,3}+(4-2)\cdot\binom{\frac{18}{3}}{\frac{9}{3},\frac{6}{3},\frac{3}{3}}\right]-\frac{1}{4}\left[\binom{2}{1,0,1}\cdot\binom{8}{4,3,1}\right]=113310\,.$$

$$A_{ac}(9,9,6,3)=\frac{1}{18}\left[(9)\cdot\binom{2}{1,0,1}\cdot\binom{8}{4,3,1}\right]=280.$$

Example 2 : Chiral and achiral graphs of $C_{12}X_9L_3Y_6Z_6$.

Let $n=12$, $m_1=9,\ m_2=3,\ m_3=6,\ m_4=6$, $D_{12}=\{1,2,3,4,6,12\}$,

$P=\{[1^{24}],\ 21[2^{12}],\ 2[3^8],\ 4[4^6],\ 6[6^4],\ 8[12^2],\ 6[1^4 2^{10}]\}$,

$P'=\{[1^{24}],\ 13[2^{12}],\ 2[3^8],\ 2[4^6],\ 2[6^4],\ 4[12^2]\}$. The set of common divisors of the sequence (24, 9, 3, 6) is $D_c=\{1,3\}$, $a_1=a_1'=1$, $a_3=a_3'=2$. The empirical formula contains *k=4* types of substituents. The solutions of the 2 associated partition equations $p_1+p_2+p_3+p_4=4$ and $m_1'+m_2'+m_3'=10$ which verify equation (13) are given in each line of the following matrices :

$$(p_1,p_2,p_3,p_4)=\begin{pmatrix}3&1&0&0\\1&3&0&0\\1&1&2&0\\1&1&0&2\end{pmatrix}\rightarrow(m_1',m_2',m_3',m_4')=\begin{pmatrix}3&1&3&3\\4&0&3&3\\4&1&2&3\\4&1&3&2\end{pmatrix}.$$

Therefore λ=4 and from equations (18) -(19) one may obtain respectively :

$$A_c(12,9,3,6,6)=\frac{1}{48}\left[(2-1)\cdot\binom{24}{9,3,6,6}+(4-2)\cdot\binom{\frac{24}{3}}{\frac{9}{3},\frac{3}{3},\frac{6}{3},\frac{6}{3}}\right]$$
$$-\frac{1}{4}\left[\begin{matrix}\binom{4}{3,1,0,0}\cdot\binom{10}{3,1,3,3}+\binom{4}{1,3,0,0}\cdot\binom{10}{4,0,3,3}\\+\binom{4}{1,1,2,0}\cdot\binom{10}{1,1,2,3}+\binom{4}{1,1,0,2}\cdot\binom{10}{4,1,3,2}\end{matrix}\right]=11\,452\,052\,360.$$

$$A_{ac}(12,9,3,6,6)=\frac{1}{4}\left[\begin{matrix}\binom{4}{3,1,0,0}\cdot\binom{10}{3,1,3,3}+\binom{4}{1,3,0,0}\cdot\binom{10}{4,0,3,3}\\+\binom{4}{1,1,2,0}\cdot\binom{10}{1,1,2,3}+\binom{4}{1,1,0,2}\cdot\binom{10}{4,1,3,2}\end{matrix}\right]=96\,600.$$

The problem of counting chiral and achiral forms of molecules is often encountered by organochemists involved in the synthesis of stereo and position isomers in the series of substituted derivatives of monocyclic cycloalkanes where the ring size *n* ranges from *3* to *288* according to the Chemical Abstract Service (CAS) ring System Handbook[9]. Examples 1 and 2 and the sequences $A_c(n,m_1,...,m_i,...,m_k)$ and $A_{ac}(n,m_1,...,m_i,...,m_k)$ given in table 1 for the systems $C_nX_{m_1}Y_{m_2}Z_{m_3}$ illustrate the selectivity and the general application of our pattern inventory. Furthermore, this procedure circumvents the two main steps of Pólya's counting method [1,2] which is largely presented by Pólya,Tarjan and Woods[2], Harary, Palmer, Robinson and Read[10],Tucker[11] and Rouvray[12] and requires first to derive a cycle index according to the parity and the divisibility character of the ring size *n*, and second the transformation of the cycle index into a generating function of order *2n* the coefficients of which are solution of the enumeration problem. Finally the accuracy of our theoretical results is testify by the method of drawing and counting graphs of systems with smaller ring size.

Table 1 : *Number of chiral and achiral graphs of polyheterosubstituted cycloalkane* $C_n X_{m_1} Y_{m_2} Z_{m_3}$,

where $n = 3, 4, 5, 6, 8$ and $m_1 + m_2 + m_3 = 2n$.

Abstract

In this paper we define the function ${}_vM_m(s;a,z)$, and we study the special cases ${}_1M_m(s;a,z)$ and ${}_nM_{-1}(1;1,n+1)$. We prove some new equivalents of Kurepa's hypothesis for the left factorial. Also, we present a generalization of the alternating factorial numbers.

1 Introduction

Studying the Kurepa function

$$K(z)=!z=\int_0^{+\infty}\frac{t^z-1}{t-1}\,e^{-t}\,dt\quad(\operatorname{Re}z>0),$$

G. V. Milovanović gave a generalization of the function

$$M_m(z)=\int_0^{+\infty}\frac{t^{z+m}-Q_m(t;z)}{(t-1)^{m+1}}e^{-t}dt\quad(\operatorname{Re}z>-(m+1)),$$

where the polynomials $Q_m(t;z)$, $m=-1,0,1,2,\ldots$ are given by

$$Q_{-1}(t;z)=0\quad Q_m(t;z)=\sum_{k=0}^{m}\binom{m+z}{k}(t-1)^k.$$

This work was supported in part by the Serbian Ministry of Science, Technology and Development under Grant # 2002: *Applied Orthogonal Systems, Constructive Approximation and Numerical Methods.*

The function $\{M_m(z)\}_{m=-1}^{+\infty}$ has the integral representation

$$M_m(z) = \frac{z(z+1)\cdots(z+m)}{m!} \int_0^1 \xi^{z-1}(1-\xi)^m e^{(1-\xi)/\xi} \Gamma\Big(z, \frac{1-\xi}{\xi}\Big)\, d\xi,$$

where $\Gamma(z,x)$, the incomplete gamma function, is defined by

$$\Gamma(z,x) = \int_x^{+\infty} t^{z-1}e^{-t}\, dt. \tag{1}$$

Special cases include

$$M_{-1}(z) = \Gamma(z) \qquad \text{and} \qquad M_0(z) = K(z), \tag{2}$$

where $\Gamma(z)$ is the gamma function

$$\Gamma(z) = \int_0^{+\infty} t^{z-1}e^{-t}\, dt.$$

The numbers $M_m(n)$ were introduced by Milovanović [10] and Milovanović and Petojević [11]. For non-negative integers $n, m \in \mathbb{N}$ the following identities hold:

$$M_m(0) = 0, \quad M_m(n) = \sum_{i=0}^{n-1} \frac{(-1)^i}{i!} \sum_{k=i}^{n-1} k! \binom{m+n}{k+m+1}.$$

For the numbers $M_m(n)$ the following relations hold:

$$\begin{aligned} M_m(n+1) &= n! + \sum_{\nu=0}^{m} M_\nu(n), \\ \lim_{n\to+\infty} \frac{M_\nu(n)}{M_{\nu-1}(n)} &= 1, \\ \lim_{n\to+\infty} \frac{M_m(n)}{(n-1)!} &= 1. \end{aligned}$$

The generating function of the numbers $\{M_m(n)\}_{n=0}^{+\infty}$ is given by

$$\frac{1}{m!}\left(A_m(x)e^{x-1}\left(\mathrm{Ei}\,(1) - \mathrm{Ei}\,(1-x) + B_m(x)e^x - C_m(x)\right)\right) = \sum_{n=0}^{+\infty} M_m(n)\,\frac{x^n}{n!}$$

where $A_m(x)$, $B_m(x)$, and $C_m(x)$ are polynomials defined as follows:

$$\begin{aligned} \frac{A_m(x)}{m!} &= \sum_{k=0}^{m} \binom{m}{k} \frac{(x-1)^k}{k!}, \\ \frac{B_m(x)}{m!} &= \sum_{\nu=0}^{m-1} \left(\sum_{k=1}^{m-\nu} \binom{m}{k+\nu} \frac{(-1)^{k-1}}{k} \sum_{j=0}^{k-1} \frac{(-1)^j}{j!} \right) \frac{(x-1)^\nu}{\nu!}, \\ \frac{C_m(x)}{m!} &= \sum_{j=0}^{m-1} \left(\sum_{\nu=0}^{j} (-1)^\nu \binom{j}{\nu} \sum_{k=j+1}^{m} \frac{(-1)^{k-1}}{k-\nu} \binom{m}{k} \right) \frac{(x-1)^j}{j!}, \end{aligned}$$

Here $\mathrm{Ei}\,(x)$ is the exponential integral defined by

$$\mathrm{Ei}\,(x) = \mathrm{p.v.}\int_{-\infty}^{x} \frac{e^t}{t}\,dt \qquad (x > 0). \tag{3}$$

In this paper, we give a generalization of the function $M_m(z)$ which we denote as ${}_vM_m(s;a,z)$. These generalization are of interest because its special cases include:

$$\begin{aligned} {}_1M_1(1;1,n+1) &= n!, \\ {}_1M_0(1;1,n) &= !n, \\ {}_nM_{-1}(1;1,n+1) &= A_n. \end{aligned}$$

where $n!$, $!n$, and A_n are the *right factorial numbers* (sequence A000142 in [17]), the *left factorial numbers* (sequence A003422 in [17]) and the *alternating factorial numbers* (sequence A005165 in [17]), respectively. They are defined as follows:

$$0! = 1,\ n! = n\cdot(n-1)!; \qquad !0 = 0,\ \ !n = \sum_{k=0}^{n-1} k! \quad \text{and} \quad A_n = \sum_{k=1}^{n}(-1)^{n-k}k!. \tag{4}$$

2 Definitions

We now introduce a generalization of the function $M_m(z)$.

Definition 1 *For $m = -1, 0, 1, 2, ...,$ and $\mathrm{Re}\, z > v - m - 2$ the function ${}_vM_m(s;a,z)$ is defined by*

$$\begin{aligned} &{}_vM_m(s;a,z) = \\ &= \sum_{k=1}^{v} \frac{(-1)^{2v+1-k}\Gamma(m+z+2-k)}{\Gamma(z+1-k)\Gamma(m+2)}\,\mathcal{L}[s;\ {}_2F_1(a,k-z,m+2,1-t)], \end{aligned}$$

where v is a positive integer, and s, a, z are complex variables.

The hypergeometric function ${}_2F_1(a,b;c,x)$ is defined by the series

$${}_2F_1(a,b,c;x) = \sum_{n=0}^{\infty} \frac{(a)_n(b)_n}{(c)_n}\frac{x^n}{n!} \qquad (|x| < 1),$$

and has the integral representation

$${}_2F_1(a,b,c;x) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)}\int_0^1 t^{b-1}(1-t)^{c-b-1}(1-tx)^{-a}dt,$$

in the x plane cut along the real axis from 1 to ∞, if $\mathrm{Re}\, c > \mathrm{Re}\, b > 0$.
The symbols $(z)_n$ and $\mathcal{L}[s; F(t)]$ represent the Pochhammer symbol

$$(z)_n = \frac{\Gamma(z+n)}{\Gamma(z)},$$

and Laplace transform

$$\mathcal{L}[s; F(t)] = \int_0^\infty e^{-st} F(t) dt.$$

Table 1: The numbers ${}_1M_m(1; a, n)$ for $m = 1, 2, 3, 4$ and $a = 0, 1, 2$

$a = 0$	in [17]	$a = 1$	in [17]	$a = 2$	in [17]
${}_1M_1(1, 0, n)$	$A000217$	${}_1M_1(1, 1, n)$	$A014144$	${}_1M_1(1, 2, n)$	$A007489$
${}_1M_2(1, 0, n)$	$A000292$	${}_1M_2(1, 1, n)$	unlisted	${}_1M_2(1, 2, n)$	$A014145$
${}_1M_3(1, 0, n)$	$A000332$	${}_1M_3(1, 1, n)$	unlisted	${}_1M_3(1, 2, n)$	unlisted
${}_1M_4(1, 0, n)$	$A000389$	${}_1M_4(1, 1, n)$	unlisted	${}_1M_4(1, 2, n)$	unlisted

The term "unlisted" in Table 1 means that the sequence cannot currently be found in Sloane's on-line encyclopedia of integer sequences[17].

Lemma 1 *Let $m = -1, 0, 1, 2, \ldots$. Then*

$${}_1M_m(1; 1, z) = M_m(z).$$

Proof. The proof presented here is due to Professor G. V. Milovanović.
Since

$$(k+m+1)! = (m+1)!(m+2)_k \quad \text{and} \quad (1-z)_k = \frac{(-1)^k \Gamma(z)}{\Gamma(z-k)},$$

we have

$$\binom{m+z}{k+m+1} = \frac{\Gamma(m+z+1)}{\Gamma(z-k)(k+m+1)!} = \frac{\Gamma(m+z+1)}{\Gamma(z)(m+1)!} \cdot \frac{(1-z)_k (-1)^k}{(m+2)_k},$$

so that

$$\begin{aligned} \frac{t^{z+m} - Q_m(t; z)}{(t-1)^{m+1}} &= \sum_{k=0}^{+\infty} \binom{m+z}{k+m+1} (t-1)^k \qquad (|t-1| < 1) \\ &= \frac{\Gamma(m+z+1)}{\Gamma(z)(m+1)!} \sum_{k=0}^{+\infty} \frac{(1-z)_k (1)_k}{(m+2)_k} \cdot \frac{(1-t)^k}{k!} \\ &= \frac{\Gamma(m+z+1)}{\Gamma(z)(m+1)!} \, {}_2F_1(1, 1-z, m+2; 1-t). \end{aligned}$$

3 The function ${}_1M_m(s;a,z)$

3.1 The numbers $\{{}_1M_m(1;-n,r)\}_{r=0\ n=0\ m=-1}^{+\infty\ +\infty\ +\infty}$

We have

$$ {}_1M_m(1;-n,z) = \frac{\Gamma(m+z+1)}{\Gamma(z)\Gamma(m+2)}\,\mathcal{L}[1;\,{}_2F_1(-n,1-z,m+2;1-t)], $$

starting with the polynomials

$$ \sum_{k=0}^{\infty}\binom{m+z}{k+m+1}\binom{n}{k}(1-t)^k, \quad n\in\mathbb{N}. $$

Since

$$ (-n)_k = (-1)^k\frac{n!}{(n-k)!} $$

we have

$$ \sum_{k=0}^{\infty}\binom{m+z}{k+m+1}\binom{n}{k}(1-t)^k = \frac{\Gamma(m+z+1)}{\Gamma(z)\Gamma(m+2)}\,{}_2F_1(-n,1-z,m+2;1-t) \tag{5} $$

or, by continuation,

$$ = \pi\ \mathrm{cosec}\ \pi z\int_0^1 \xi^{1-z}(1-\xi)^{m+z+1}\big(1-(1-t)\xi\big)^n d\xi. $$

Hence, the following definition is reasonable.

Definition 2 *For $n\in\mathbb{N}$ and $m=-1,0,1,2,...$, the polynomials $z\mapsto {}_mP_n(z)$ are defined by*

$$ {}_mP_n(z) = \mathcal{L}[1;\,{}_2F_1(-n,1-z,m+2;1-t)]. $$

Table 2: The polynomials ${}_mP_2(z)$, ${}_mP_3(z)$ and ${}_mP_4(z)$

m	${}_mP_2(z)$	${}_mP_3(z)$	${}_mP_4(z)$
-1	$\frac{1}{2}z^2-\frac{3}{2}z+2$	$-\frac{1}{3}z^3+\frac{7}{2}z^2-\frac{49}{6}z+6$	$\frac{3}{8}z^4-\frac{61}{12}z^3+\frac{193}{8}z^2-$
0	$\frac{1}{6}z^2-\frac{1}{2}z+\frac{4}{3}$	$-\frac{1}{12}z^3+z^2-\frac{29}{12}z+\frac{5}{2}$	$-\frac{509}{12}z+24$
1	$\frac{1}{12}z^2-\frac{1}{4}z+\frac{7}{6}$	$-\frac{1}{30}z^3+\frac{9}{20}z^2-\frac{67}{60}z+\frac{17}{10}$	

The polynomials ${}_mP_n(z)$ can be expressed in terms of the *derangement numbers* (sequence A000166 in [17])

$$ S_k = k!\sum_{\nu=0}^{k}\frac{(-1)^\nu}{\nu!} \qquad (k\geq 0) $$

in the form

Theorem 1 *For $m = -1, 0, 1, 2, ...$ and $n \in \mathbb{N}$ we have*

$$ {}_mP_n(z) = \binom{n+m+1}{n}^{-1} \sum_{k=0}^{\infty} \binom{n+m+1}{k+m+1} \binom{z-1}{k} (-1)^k S_k. $$

Proof. Using the relation (5) we have

$$\begin{aligned} {}_mP_n(z) &= \frac{\Gamma(z)\Gamma(m+2)}{\Gamma(m+z+1)} \int_0^{\infty} e^{-t} \sum_{k=0}^{\infty} \binom{m+z}{k+m+1} \binom{n}{k} (1-t)^k dt \\ &= \frac{\Gamma(z)(m+1)!}{\Gamma(m+z+1)} \sum_{k=0}^{\infty} \frac{\Gamma(m+z+1)}{\Gamma(z-k)(k+m+1)!} \binom{n}{k} \int_0^{\infty} e^{-t}(1-t)^k dt \\ &= \binom{n+m+1}{n}^{-1} \sum_{k=0}^{\infty} \binom{n+m+1}{k+m+1} \binom{z-1}{k} \int_0^{\infty} e^{-t}(1-t)^k dt. \end{aligned}$$

Now use

$$ \mathcal{L}[s; (t+\alpha)^{z-1}] = \frac{e^{\alpha s}\Gamma(z, \alpha s)}{s^z} \qquad (\mathrm{Re}\, s > 0), $$

to obtain

$$ {}_mP_n(z) = \binom{n+m+1}{n}^{-1} \sum_{k=0}^{\infty} \binom{n+m+1}{k+m+1} \binom{z-1}{k} (-1)^k \frac{\Gamma(k+1, -1)}{e}. $$

Here $\Gamma(z, x)$ is the incomplete gamma function. The result follows from

$$ \Gamma(k+1, -1) = eS_k. $$

Lemma 2 *For $n \in \mathbb{N}$ we have*

$$ {}_{-1}P_n(z) = 1 + n! \sum_{k=1}^{n} \frac{(-1)^k S_k}{(n-k)!\,(k!)^2} \prod_{i=1}^{k} (z-i). $$

Proof. Applying Theorem 1 for $m = -1$, we have

$$\begin{aligned} {}_{-1}P_n(z) &= \sum_{k=0}^{n} \binom{n}{k} \binom{z-1}{k} (-1)^k S_k, \\ &= 1 + n! \sum_{k=1}^{n} \frac{(-1)^k S_k}{(n-k)!(k!)^2} \prod_{i=1}^{k} (z-i). \end{aligned}$$

Remark 1 *Let the sequence $X_{n,k}$ be defined by*

$$X_{n,k} = \begin{cases} Y_n, & \text{if } n = k, \\ (n-k)X_{n-1,k}, & \text{if } n > k, \end{cases}$$

where $Y_n = (n!)^2$. Since $X_{n,k} = (n-k)!\,(k!)^2$ we have

$$_{-1}P_n(z) = 1 + n! \sum_{k=1}^{n} \frac{(-1)^k S_k}{X_{n,k}} \prod_{i=1}^{k} (z-i).$$

Theorem 2 *For $m = -1, 0, 1, 2, \ldots$ and $n \in \mathbb{N}$ we have*

$$\begin{aligned} {}_mP_0(z) &= {}_mP_1(z) = 1 \\ {}_mP_n(z) &= \frac{1}{n+m+1}\left[(m+1)\,{}_{m-1}P_n(z) + n\,{}_mP_{n-1}(z)\right], \quad m > -1. \end{aligned}$$

Proof. According to Theorem 1 we have

$$\frac{1}{n+m+1}\left[(m+1)\,{}_{m-1}P_n(z) + n\,{}_mP_{n-1}(z)\right] =$$

$$\frac{(m+1)!n!}{(n+m+1)!} \sum_{k=0}^{\infty} \binom{n+m}{k+m} \binom{z-1}{k} (-1)^k S_k +$$

$$+ \quad \frac{(m+1)!n!}{(n+m+1)!} \sum_{k=0}^{\infty} \binom{n+m}{k+m+1} \binom{z-1}{k} (-1)^k S_k.$$

The recurrence for ${}_mP_n(z)$ now follows from

$$\binom{a}{b} + \binom{a}{b+1} = \binom{a+1}{b+1}.$$

Corollary 1 *For $m = -1, 0, 1, 2, \ldots$ and $n \in \mathbb{N}$ we have*

$${}_1M_m(1; -n, z) = \frac{n!\,z(z+1)\ldots(z+m)}{(n+m+1)!} \sum_{k=0}^{\infty} \binom{n+m+1}{k+m+1} \binom{z-1}{k} (-1)^k S_k.$$

Corollary 2 *For $n \in \mathbb{N}$ the result is as follows*

$$\begin{aligned} {}_1M_{-1}(1;-n,z) &= 1+n!\sum_{k=1}^{n}\frac{(-1)^k S_k}{(n-k)!\,(k!)^2}\prod_{i=1}^{k}(z-i), \\ {}_1M_m(1;0,z) &= {}_1M_m(1;-1,z)=\frac{\Gamma(m+z+1)}{\Gamma(z)\Gamma(m+2)}, \\ {}_1M_m(1;-n,z) &= \frac{1}{n+m+1}\cdot[\,(m+z)\cdot {}_1M_{m-1}(1;-n,z)+ \\ &+ n\cdot {}_1M_m(1;-n+1,z)], \quad m>-1. \end{aligned}$$

The numbers ${}_1M_m(1;-n,r)_{r=0}^{\infty}$ can now be evaluated recursively.

Table 3: The numbers ${}_1M_m(1;-n,r)$ for $m=0,1,2,3,4$ and $n=1,2$

${}_1M_m(1,-n,r)$	sequence in [17]	${}_1M_m(1,-n,r)$	sequence in [17]

3.2 The numbers $\{{}_1M_m(1/n;m+2,r)\}_{r=0}^{+\infty}{}_{n=1}^{+\infty}{}_{m=-1}^{+\infty}$

In Table 4 twelve well-known sequences from [17] are given. These sequences are special cases of the function ${}_vM_m(s;a,r)$ for $v=1$, $s=1/n$, and $a=m+2$. The sequences have the following common characteristic.

Lemma 3 *For $m=-1,0,1,2,...,$ we have*

$${}_1M_m(1/n;m+2,z)=\frac{n^z\Gamma(z+m+1)}{(m+1)!}.$$

Proof. Since

$${}_2F_1(m+2,1-z,m+2,1-t)=t^{z-1}$$

we have

$$\mathcal{L}[1/n;\,{}_2F_1(m+2,1-z,m+2,1-t)]=n^z\Gamma(z).$$

Table 4: The numbers ${}_1M_m(1/n; m+2, r)$ for $m = -1, 0, 1, 2, 3, 4$ and $n = 1, 2, 3, 4$

3.3 Some equivalents of Kurepa's hypothesis

The special values $M_{-1}(z) = \Gamma(z)$ and $M_0(z) = K(z)$ given in (2) yield

$$ {}_1M_{-1}(1, 1, n+1) = n! \quad \text{and} \quad {}_1M_0(1; 1, n) = !n \tag{6}$$

where $n!$ and $!n$ are the right factorial numbers and the left factorial numbers given in (4). The function $n!$ and $!n$ are linked by Kurepa's hypothesis:

KH hypothesis. *For $n \in \mathbb{N}\backslash\{1\}$ we have*

$$\gcd(\, !n,\, n!\,) = 2$$

where $\gcd(a, b)$ denotes the greatest common divisor of integers a and b.

This is listed as Problem B44 of Guy's classic book [6]. In [8], it was proved that the KH is equivalent to the following assertion

$$!p \not\equiv 0 \pmod{p}, \quad \text{for all primes } p > 2.$$

The sequences a_n, b_n, c_n, d_n and e_n (sequences A052169, A051398, A051403, A002467 and A002720 in [17]) are defined as follows:

$$\begin{array}{lllll} a_2=1 & a_3=2 & a_n & = & (n-2)a_{n-1}+(n-3)a_{n-2}, \\ & b_3=2 & b_n & = & -(n-3)b_{n-1}+2(n-2)^2, \\ c_1=3 & c_2=8 & c_n & = & (n+2)(c_{n-1}-c_{n-2}), \\ d_0=0 & d_1=1 & d_n & = & (n-1)(d_{n-1}+d_{n-2}), \\ e_0=1 & e_1=2 & e_n & = & 2ne_{n-1}-(n-1)^2e_{n-2}. \end{array}$$

They are related to the left factorial function. For instance, let $p>3$ be a prime number. Then

$$!p \equiv -3a_{p-2} \equiv -b_p \equiv -2c_{p-3} \equiv d_{p-2} \equiv e_{p-1} \pmod{p}.$$

We give the details for the last congruence.

Proof. Let

$$L_n^{\nu}(x)=\sum_{k=0}^{n}\frac{\Gamma(\nu+n+1)}{\Gamma(\nu+k+1)}\frac{(-x)^k}{k!(n-k)!}$$

be the Laguerre polynomials, and set $L_n^0(x)=L_n(x)$. Using the relation $\binom{p-1}{k} \equiv (-1)^k \pmod{p}$, we have

$$L_{p-1}(x) \equiv -(p-1)!\sum_{k=0}^{p-1}\frac{x^k}{k!} \pmod{p}.$$

Wilson's theorem yields

$$!p \equiv -L_{p-1}(-1) \pmod{p}.$$

The recurrence for Laguerre polynomials

$$(n+1)L_{n+1}^{\nu}(x)=(\nu+2n+1-x)L_n^{\nu}(x)-(\nu+n)L_{n-1}^{\nu}(x),$$

for $\nu=0,\ x=-1$ produces

$$h_{p-1}(p-1)! \equiv p \pmod{p},$$

where

$$h_1=2 \quad h_2=\frac{7}{2} \quad h_n=2h_{n-1}-\frac{n-1}{n}h_{n-2}.$$

The identity $e_n=h_n n!$ finally yields

$$!p \equiv e_{p-1} \pmod{p}.$$

4 The numbers ${}_nM_{-1}(1;1,n+1)$

The special values

$$ {}_nM_{-1}(1;1,n+1) = A_n, $$

are the alternating factorial numbers given in (4). This sequence satisfies the recurrence relation

$$ A_0 = 0,\ A_1 = (-1)^{n-1},\ A_n = -(n-1)A_{n-1} + nA_{n-2}. $$

These numbers can be expressed in terms of the gamma function as follows

$$ \begin{aligned} A_n &= \sum_{k=1}^{n}(-1)^{n-k}\Gamma(k+1) = \int_0^\infty e^{-x}\left(\sum_{k=1}^{n}(-1)^{n-k}x^k\right)dx \\ &= \int_0^\infty e^{-x}\frac{x^{n+1}-(-1)^n x}{x+1}dx. \end{aligned} $$

The same relation is now used in order to define the function A_z:

Definition 3 *For every complex number z, $Re\ z > 0$, the function A_z is defined by*

$$ A_z \stackrel{\text{def}}{=} \int_0^\infty e^{-x}\frac{x^{z+1}-(-1)^z x}{x+1}dx. $$

The identity $\frac{x^{z+1}-(-1)^z x}{x+1} = x^z - \frac{x^z-(-1)^{z-1}x}{x+1}$ gives

$$ \int_0^\infty e^{-x}\frac{x^{z+1}-(-1)^z x}{x+1}dx = \int_0^\infty e^{-x}x^z dx - \int_0^\infty e^{-x}\frac{x^z-(-1)^{z-1}x}{x+1}dx, $$

i.e.,

$$ A_z = \Gamma(z+1) - A_{z-1}. \tag{7} $$

This gives $A_0 = \Gamma(2) - A_1 = 0$ and $A_{-1} = \Gamma(1) - A_0 = 1$. An inductive argument shows that A_{-n}, the residue of A_z at the pole $z = -n$, is given by

$$ res\ A_{-n} = (-1)^n \sum_{k=0}^{n-2}\frac{1}{k!}, \qquad n = 2,3,4,... $$

The derivation employs the fact that $\Gamma(z)$ is meromorphic with simple poles at $z = -n$ and residue $(-1)^n/n!$ there.

The function A_z can be expressed in terms of the exponential integral $\mathrm{Ei}\,(x)$ and the incomplete gamma function $\Gamma(z,x)$ by

$$ A_z = \mathcal{L}[1;\ \frac{t^{z+1}-(-1)^z}{t+1}] = e\Gamma(z+2)\Gamma(-z-1,1) - (-1)^z e\mathrm{Ei}\,(-1) - (-1)^z. $$

4.1 The generating function for A_{n-1}

The *total number of arrangements of a set with n elements* (sequence A000522 in [17]) is defined (see [3], [5], [15] and [16]) by:

$$a_0 = 1, \quad a_n = na_{n-1} + 1, \quad \text{or} \quad a_n = n! \sum_{k=0}^{n} \frac{1}{k!}. \tag{8}$$

The sequence $\{a_n\}$ satisfies:

$$a_0 = 1, \quad a_1 = 2, \quad a_n = (n+1)a_{n-1} - (n-1)a_{n-2}, \tag{9}$$

and

$$a_0 = 1, \quad a_n = \sum_{k=0}^{n-1} \binom{n}{k} (-1)^{n+1-k}(n+1-k)a_k. \tag{10}$$

Relation (9) comes from the theory of continued fractions and (10) follows directly from (8).

We now establish a connection between the sequence $\{a_n\}$ and the alternating factorial numbers A_n.

Lemma 4 *Let* $a_{-1} = 1$ *and* $n \in \mathbb{N}\backslash\{1\}$. *Then*

$$A_{n-1} = \sum_{k=0}^{n} \binom{n}{k} (-1)^{n-k} a_{k-1}.$$

Proof. Using (10) and induction on n we have

$$n! = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} a_k.$$

Inversion yields

$$a_n = n! - \sum_{k=1}^{n} \binom{n}{k-1} (-1)^{n+1-k} a_{k-1}.$$

The relation $\binom{n+1}{k} - \binom{n}{k} = \binom{n}{k-1}$, $k \geq 1$ produces

$$\sum_{k=0}^{n+1} \binom{n+1}{k} (-1)^{n+1-k} a_{k-1} + \sum_{k=0}^{n} \binom{n}{k} (-1)^{n-k} a_{k-1} = n!.$$

The result now follows from (7).

Theorem 3 *The exponential generating function for* $\{A_{n-1}\}$ *is given by*

$$g(x) = e^{1-x}[E_i(-1) - E_i(x-1) + e^{-1}] - 1 = \sum_{n=2}^{\infty} A_{n-1} \frac{x^n}{n!},$$

where $E_i(x)$ *is the exponential integral (3).*

Proof. The expansion of the exponential integral

$$E_i(x) = \gamma + \ln(x) + \sum_{k=1}^{\infty} \frac{x^k}{k \cdot k!},$$

where γ is Euler's constant, appears in [1, p. 57, 5.1.10.]. The statement of the theorem can be written as

$$e[E_i(-1) - E_i(x-1) + e^{-1}] = e\left[-\ln(x-1) + \sum_{k=1}^{\infty} \frac{(-1)^k - (x-1)^k)}{k \cdot k!}\right] =$$

$$= \sum_{k=0}^{\infty} a_{k-1} \frac{x^k}{k!}. \tag{11}$$

Expand e^{-x} as a Taylor series to obtain

$$e^{-x} = \sum_{k=0}^{\infty} (-1)^k \frac{x^k}{k!}.$$

Then

$$\begin{aligned} e^{1-x}[E_i(-1) - E_i(x-1) + e^{-1}] - 1 &= \sum_{k=0}^{\infty} a_{k-1} \frac{x^k}{k!} \sum_{k=0}^{\infty} (-1)^k \frac{x^k}{k!} - 1 \\ &= \sum_{n=0}^{\infty} \sum_{k=0}^{n} a_{k-1} \frac{x^k}{k!} (-1)^{n-k} \frac{x^{n-k}}{(n-k)!} - 1 \\ &= \sum_{n=0}^{\infty} \sum_{k=0}^{n} \binom{n}{k} a_{k-1} (-1)^{n-k} \frac{x^n}{n!} - 1 \\ &= \sum_{n=0}^{\infty} A_{n-1} \frac{x^n}{n!} - 1. \end{aligned}$$

By induction on n we get

Lemma 5 *Let $n \in N$. The function $g(x)$ in Theorem 4.1 satisfies*

$$g^{(n)}(x) = \frac{d}{dx} g^{(n-1)}(x) = (-1)^n \left[g(x) + 1 + \sum_{k=0}^{n-1} \frac{k!}{(x-1)^{k+1}}\right].$$

This identity gives the algorithm for computing the n-th derivation of the function $g(x)$.

4.2 The AL hypothesis

In [6, p. 100] the following problem is given:

Problem B43. Are there infinitely many numbers n such that A_{n-1} is a prime?

Here

$$A_n = \sum_{k=1}^{n} (-1)^{n-k} k!.$$

If there is a value of $n-1$ such that n divides A_{n-1}, then n will divide A_{m-1} for all $m > n$, and there would be only a finite number of prime values. The required condition for the existence of infinitely many numbers n such that A_{n-1} is a prime may be expressed as follows:

AL hypothesis. *For every prime number p*

$$A_{p-1} \not\equiv 0 \pmod{p},$$

holds.

Let p be a prime number and $n, m \in \mathbb{N}\backslash\{1\}$. It is not difficult to prove the following results:

$$A_{n-1} \equiv -1 - \sum_{k=2}^{n} [k - 1 - (-1)^{n-k}]\Gamma(k) \pmod{n},$$

$$\begin{aligned} A_{n-1} &= \frac{\Gamma(n+1) - 1 + \sum_{k=2}^{n-1}[(-1)^{n-k}n - k + 1 - (-1)^{n-k}]\Gamma(k)}{n-1}, \\ &= 1-!n + 2\sum_{k=1}^{n-1} A_k \\ &= 3-!n-!(n-1)\cdot 2n + 4\sum_{i=2}^{n}\sum_{k=1}^{i-1} A_k. \end{aligned}$$

$$\sum_{k=1}^{n}\sum_{i=0}^{m-1}(-1)^i(\Gamma(k+1))^{m-i}A_{k-1}^i = \begin{cases} A_n^m, & m \text{ even} \\ A_n^m + 2\sum_{j=1}^{n-1} A_j^m, & m \text{ odd} \end{cases},$$

$$A_{p-1} = -\sum_{i=1}^{p}\frac{1}{\Gamma(i)} + p\sum_{i=1}^{p}\frac{n_i(-1)^{i-1}}{\Gamma(i)}, \quad n_i \in \mathbb{N} \quad (i = 1, 2, ...p)$$

The first step in solving problem B43 is proving the AL hypothesis. Using the previous identities, equivalents for the AL hypothesis can be given.

5 Conclusions

The main contribution is to define the function ${}_vM_m(s;a,z)$ by which problems B43 and B44 are connected. The Kurepa hypothesis is an unsolved problem since 1971 and there seems to be no significant progress in solving it, apart from numerous equivalents, such as these in Section 3.3. Further details can be found in [7].

However, apart from $n!$, $!n$, and A_n, twenty-five more well-known sequences in [17] are special cases of the function ${}_vM_m(s;a,z)$. The first study of the function gave the author the idea to find an algorithm for computing some special cases (Corollary 2 and Lemma 3) before solving the above mentioned problems.

The definition of the function ${}_vM_m(s;a,z)$ suggest another method of studying the function by using the characteristics of the inverse Laplace transform.

Carmichael Numbers of the form $(6m+1)(12m+1)(18m+1)$

Harvey Dubner

449 Beverly Road
Ridgewood, New Jersey 07450
USA

hdubner1@compuserve.com

Abstract

Numbers of the form $(6m+1)(12m+1)(18m+1)$ *where all three factors are simultaneously prime are the best known examples of Carmichael numbers. In this paper we tabulate the counts of such numbers up to* 10^n *for each* $n \leq 42$*. We also derive a function for estimating these counts that is remarkably accurate.*

1 Introduction

Fermat's "Little Theorem" says that if a is any integer prime to N, and if N is prime, then

$$a^{N-1} \equiv 1 \pmod{N}.$$

However, this is not a sufficient condition for a number to be prime since there are composite numbers known as Carmichael numbers which satisfy this congruence. Carmichael numbers meet the following criterion,

Korselt's criterion (1899). *A composite odd number* N *is a Carmichael number if and only if* N *is squarefree and* $p-1$ *divides* $N-1$ *for every prime* p *dividing* N*.*

Considerable progress has been made investigating Carmichael numbers in the past several years. Alford, Granville and Pomerance showed that there are infinitely many Carmichael numbers [1]. Löw and Niebuhr constructed Carmichael numbers with millions of components [6]. Balasubramanian and Nagaraj established an upper bound for the number of 3-component Carmichael numbers up to x that is a little more than $x^{1/3}$ [2]. Granville and Pomerance have developed several conjectures which seem to resolve some serious inconsistencies concerning the total number of Carmichael numbers [4]. These various conjectures are supported by counts of Carmichael numbers mostly done by Richard Pinch [8, 9]. However, in many cases the data is too limited to fully support some of the conjectures.

The main purpose of this paper is to supply accurate extended counts of an important family of 3-component Carmichael numbers. Chernick in 1939 [3] derived one-parameter expressions for Carmichael numbers which he called "Universal Forms," the most prominent of these being

$$U_3(m) = (6m + 1)(12m + 1)(18m + 1). \tag{1}$$

$U_3(m)$ is a Carmichael number when the quantities in parentheses are simultaneously prime. There are indications that this family represents about 2.2% of the 3-component Carmichael numbers, more than any such family.

2 Search Method

The method used to search for and count numbers of the form (1) depends almost entirely on sieving. An array of 32,000,000 bits represents values of $q = 6m + 1$ from $m = m_0$ to $m = m_0 + 31,999,999$. For each "small" prime from 5 to an appropriate maximum, each q is marked as composite when divisible by a small prime (i.e., the bit is turned on). With a slight program addition it can be determined if $r = 12m+1$ or $s = 18m+1$ has a factor, and if it does then q is also marked as composite even though q itself might actually be prime.

Typically, in the vicinity of $U_3 = 10^{41}$, about 18,000 numbers survive this sieving process which takes about 27 seconds on an Athlon/1.2 GHz computer. No additional tests are required since all three components of (1) must be prime and therefore the survivors are Carmichael numbers of the required form. The only additional processing needed is to determine the sizes of all the survivors and to do appropriate bookkeeping which takes about 1 second.

This process is repeated for the next block of 32,000,000 m's. It is easy to use multiple computers to get complete counts since the results for each block is independent of all other blocks. To extend the count from 10^{41} to 10^{42} took about 30 computer-days (Athlon/1.2 GHz). Compute time for each decade takes about 2.2 times as long as the previous decade. Thus, extending the count an additional decade takes about the same time as it took for all

the previous counts.

3 Theoretical Count

It is interesting and important to try to estimate the the number of Carmichael numbers of the form $U_3(m)$ that are less than a given X. The famous Hardy-Littlewood conjectures [5] will be used as a model. We follow the theory as described in detail in Riesel's book [10, p. 60].

Consider a number of the form (1),

$$u = q \cdot r \cdot s, \quad \text{where} \quad q = 6m + 1, \quad r = 12m + 1, \quad s = 18m + 1. \tag{2}$$

If q were chosen at random, by the Prime Number Theorem the probability of q being prime would be $1/\log q$ asymptotically. However in our case q can never be divisible by 2 or 3. When a number cannot be divided by a prime, p, the probability of the number being prime increases by the factor $p/(p-1)$. Thus the probability of q being prime is increased by the factor $(2/1)(3/2) = 3$ and becomes

$$P_q = \frac{3}{\log(6m+1)}. \tag{3}$$

As with q, r cannot have 2 or 3 as a factor, but its primality is also affected if q is prime. Normally the chance that a prime p will not divide r is $(p-1)/p$ because $(q \bmod p)$ has $(p-1)$ values which are not zero. However, since $r = q + 6m$ it is easy to show that if q is prime then $(r \bmod p)$ has only $(p-2)$ values which are not zero—thus dropping the probability that r is prime by the factor $(p-2)/(p-1)$. The correction factor, $C_r(p)$, for p is,

$$C_r(p) = \frac{p}{(p-1)} \cdot \frac{(p-2)}{(p-1)} = \frac{p(p-2)}{(p-1)(p-1)}$$

The full correction factor is the product of these for $p = 5, 7, 11, 13, \cdots \infty$,

$$C_r = \prod_{5}^{\infty} \frac{p(p-2)}{(p-1)(p-1)} \doteq .880216$$

and the probability of r being prime becomes,

$$P_r = 3 \cdot C_r \cdot \frac{1}{\log(12m+1)} = \frac{2.640648}{\log(12m+1)}\ . \tag{4}$$

Similarly, the full correction factor for s is

$$C_s = \prod_{5}^{\infty} \frac{p(p-3)}{(p-1)(p-2)} = .721604$$

and the probability of s being prime becomes,

$$P_s = 3 \cdot C_s \cdot \frac{1}{\log(18m+1)} = \frac{2.164812}{\log(18m+1)} \ . \tag{5}$$

For a given m the probability of q, r and s being prime simultaneously is,

$$P_{qrs} = P_q \cdot P_r \cdot P_s = \frac{17.14952}{\log(6m+1)\log(12m+1)\log(18m+1)} \ . \tag{6}$$

Summing this probability over all appropriate m gives an estimate for the number of such Carmichael numbers less than a given X. To facilitate the computation we replace the summation by integration, and replace the Carmichael number components with,

$$\log(6m+1)\log(12m+1)\log(18m+1) = \log^3(a_x m),$$

where a_x is determined by evaluating the above expression at $m = M = (X/1296)^{1/3}$, the maximum value of m corresponding to a given X.

The estimate now becomes,

$$E(X) = 17.14952 \sum_{m=1}^{M} \frac{1}{\log^3(a_x m)} \approx 17.14952 \int_1^M \frac{dm}{\log^3(a_x m)} \ . \tag{7}$$

To numerically evaluate $E(X)$, integrate by parts twice giving,

$$E(X) \approx \frac{17.14952}{2a_x} \left[\int^{a_x M} \frac{dx}{\log(x)} - \frac{a_x M}{\log(a_x M)} - \frac{a_x M}{\log^2(a_x M)} \right] \ . \tag{8}$$

The above integral term is the well-known logarithmic integral function, $L_i(x)$, which is easy to accurately evaluate numerically. Lower limits are omitted since they have negligible effect on the totals.

4 Results

Table 1 shows the actual counts of $(6m+1)(12m+1)(18m+1)$ Carmichael numbers and the estimated counts from Eq. (8). The errors and percentage errors are also shown. The estimates are remarkably close to the actual counts.

Although we do not know the exact probability distribution of the counts, we can make the reasonable assumption that they can be approximated by a Poisson distribution since this is true for almost all distributions of rare phenomena. We can then present the error as the number of standard deviations, which effectively normalizes the error. If $N(X)$ is the actual number of Carmichael numbers found up to X, and $E(X)$ is the estimated number then

$$\text{error in standard deviations } = \frac{N(X) - E(X)}{\sqrt{E(X)}} \ .$$

This is the last column in Table 1. Almost all these normalized errors are within one standard deviation, excellent results which support the accuracy of the theoretical estimating function over a wide range of of values.

Table 1: Count of $(6m+1)(12m+1)(18m+1)$ Carmichael Numbers up to X

5 Estimating $C_3(X)$ for large X

The 3-component Carmichael numbers can be expressed in the form

$$(am+1)(bm+1)(cm+1), \quad a<b<c, \quad a,b,c \text{ relatively prime in pairs.}$$

As shown in Ore's book [7, Ch. 14], $m = m_0 + k(abc)$, $k = 1, 2, 3\ldots$, where m_0 is the solution to the linear congruence

$$m_0(ab+ac+bc) \equiv -(a+b+c) \pmod{abc}.$$

Thus, for a given a, b, c it is easy to find all allowable values of m. All that remains is to test the three components for primality for each allowable m. In this way a "family" of Carmichael numbers is found corresponding to (a, b, c). Our 6–12-18 Carmichael numbers are the $(1, 2, 3)$ family.

From another project we found that part of the process of counting 3-component Carmichael numbers, $C_3(X)$ could be greatly speeded up if we counted by families. For example, finding all such numbers less than 10^{18}, took about 1100 hours using a Pentium III/550 MHz. However, we found 64.4% of them in about 4 hours by limiting the search to all families with $a = 1$, that is $(1, b, c)$. We repeated this for a wide range of X and found that the time improvement factor of about 300 was consistant and the ratios of Carmichael numbers found to $C_3(X)$ were remarkably similar. The results are shown in Table 2.

Having accurate values for $C_3(10^n)$ for large values of n is quite desirable to support various conjectures in [4]. Exhaustive searching is now used to obtain exact counts, but even with the continuing cost-performance improvement in computing hardware it takes much too long to extend the count for each additional decade. It seems we should consider sacrificing some accuracy in determining $C_3(10^n)$ if the upper limit of n can be extended in a practical manner.

Note the percentage columns of Table 2. The counts of $(1, a, b)$ are about 64.4% of the corresponding $C_3(10^n)$ for a wide range of n. Similarly the counts of $(1, 2, 3)$ are about 2.2% of $C_3(10^n)$, and appear to be closely correlated to counts of $(1, a, b)$. If we assume these correlations continue for larger values of n then the actual counts of the $(1, 2, 3)$ family possibly could be used to estimate $C_3(10^n)$ up to $n = 42$ with about 1% accuracy. Optimistically, this might even be extended for $n > 42$ by using the estimates from Eq. (8).

However, it must be remembered that all these results are heuristic, and although interesting they require more rigorous theory and study. One area for future research is to relate the above results to the conjectures and conclusions of the Granville and Pomerance paper [4].

Abstract

We study the minimal density of letters in infinite square-free words. First, we give some definitions of minimal density in infinite words and prove their equivalence. Further, we propose a method that allows to strongly reduce an exhaustive search for obtaining lower bounds for minimal density. Next, we develop a technique for constructing square-free morphisms with extremely small density for one letter that gives upper bounds on the minimal density. As an application of our technique we prove that the minimal density of any letter in infinite ternary square-free words is $0.2746\cdots$.

A word is called *square-free* if it cannot be written in the form $axxb$ for two words a, b and a nonempty word x. It is easy to see that the maximal length of a binary square-free word is 3. A. Thue proved [8] that there exist ternary square-free words. The number of ternary square-free words of length n is given by the sequence **A006156** in The Encyclopedia of Integer Sequences [7]. Ekhad and Zeilberger [2] proved that the number of ternary square-free words of length n is at least $2^{n/17}$. Grimm [3] gave a better bound; he proved that this number is at least $65^{n/40}$. Note that not every finite square-free word can be extended to an infinite square-free word. In this paper we prove that the minimal density of any letter in an infinite ternary square-free word is $0.2746\cdots$.

1 Preliminary concepts and notions

Let M be a finite alphabet, and let M^* be the free monoid over M. Let M^ω be the set of one-sided infinite words over M (or mappings from $\mathbf{N} \to M$). A word $v \in M^*$ is called a *factor* of the word $w \in M^*$ if w can be written as $w = v_1 v v_2$ for some $v_1, v_2 \in M^*$. If v_1 is the empty word, then v is called also a *prefix* of w. Let $F \subseteq M^*$. Denote by $l(F)$ the length of the longest word in F; if the set F is infinite we define $l(F) := \infty$. The set F for $F \subseteq M^*$ is called a *factorial language* if for any word $w \in F$ the set F contains every factor of w. The length of the word w is denoted by $|w|$.

Any set G of forbidden factors in M^* generates a factorial language $F = F(G)$ where

$$F(G) = \{w \in M^* \mid \forall v \in G \quad v \text{ is not a factor of } w\}.$$

Indeed, if the word $w \in F(G)$ does not contain any word $v \in G$ then no factor u of w contains such a word, either.

We denote by $F^\omega \subseteq M^\omega$ the set of all infinite words with every finite factor belonging to F.

Proposition 1.1 *The set F^ω is not empty iff the language F is infinite.*

Proof. If the language F is finite then obviously the set F^ω is empty. If the language F is infinite then we can construct an infinite word with every finite prefix belonging to F by König's Infinity Lemma. It is easy to see that this word belongs to F^ω. ∎

Denote by $a(w)$ the number of occurrences of a letter $a \in M$ in the word $w \in F$. The proportion $\rho_a(w) = \frac{a(w)}{|w|}$ is called the *density* of the letter a in the finite word w. To define the density of a letter in the infinite word w is a more complicated problem. We can consider the sequence $(\rho_a(w_n))$, $n = 1, 2, \ldots$, where w_n is the prefix of w of length n but it is possible that this sequence does not converge to a limit. An example of such a situation is given by the infinite word

$$w = a\underbrace{b\ldots b}_{10}\ \underbrace{a\ldots a}_{10^2}\ \underbrace{b\ldots b}_{10^4}\ \underbrace{a\ldots a}_{10^8}\ \underbrace{b\ldots b}_{10^{16}}\ \cdots$$

It is not hard to see that for any positive integer N, positive real ε and real ξ, $0 \le \xi \le 1$, there exists $n > N$ such that $|\rho_a(w_n) - \xi| < \varepsilon$.

Thus, it is possible that the limit of the densities for the sequence of prefixes in an infinite word does not exist. Nevertheless, we can define the lower limit of this sequence.

Definition 1.1 *Let F be an infinite factorial language. We define*

$$F(l) := \{w \in F \mid\ |w| = l\};$$

$$\rho_a(F, l) := \min_{w \in F(l)} \rho_a(w);\ \text{and}$$

$$\rho_a(F) := \varliminf_{l \to \infty} \rho_a(F, l).$$

The next two lemmas are proved in Kolpakov, Kucherov, and Tarannikov [4].

Lemma 1.1 *For every $l \in \mathbf{N}$, the inequality $\rho_a(F,l) \leq \rho_a(F)$ holds.*

Lemma 1.2 $\rho_a(F) = \lim\limits_{l\to\infty} \rho_a(F,l) = \sup\limits_{l\geq 1} \rho_a(F,l)$.

Thus, we can write

$$\rho_a(F) = \lim_{l\to\infty} \rho_a(F,l).$$

Definition 1.2 *We denote*

$$\mathcal{A}_a^-(\xi) = \{w \in F \,|\, \forall \text{ prefixes } u \text{ of } w:\ \rho_a(u) \leq \xi\},$$

$$\mathcal{A}_a^-(\xi-) = \{w \in F \,|\, \forall \text{ prefixes } u \text{ of } w:\ \rho_a(u) < \xi\}.$$

Theorem 1.1 *If $\rho_a(F) \leq \xi$ then the set $\mathcal{A}_a^-(\xi)$ is infinite.*

Proof. Assume the converse. Then we can decompose an arbitrary infinite word w in F^ω into $w = v_1 v_2 \ldots$ where $|v_i| \leq l(\mathcal{A}_a^-(\xi)) + 1$ and $\rho_a(v_i) \geq \rho_a(F) + \varepsilon$ for some $\varepsilon > 0$. Therefore,

$$\lim_{l\to\infty} \rho_a(F,l) \geq \rho_a(F) + \varepsilon.$$

This contradiction proves the theorem. ■

Corollary 1.1

(a) *The set $\mathcal{A}_a^-(\xi)$ is infinite iff $\xi \geq \rho_a(F)$.*

(b) *The set $\mathcal{A}_a^-(\xi-)$ is infinite iff $\xi > \rho_a(F)$.*

Corollary 1.2 *There exists a word $w \in F^\omega$ such that any prefix u of w belongs to $\mathcal{A}_a^-(\rho_a(F))$.*

Proof. We can construct easily this word w by König's Lemma on an infinite tree. ■

The above facts allow us to obtain lower bounds ξ for the minimal density of a letter a in a factorial language F proving by an exhaustive search that the set $\mathcal{A}_a^-(\xi)$ ($\mathcal{A}_a^-(\xi-)$) is finite. As it will be shown below in many cases for sufficiently small ξ this exhaustive search can be produced in a very short time.

2 Minimal letter density for some special factorial languages

For some special factorial languages the problem of finding the minimal letter density is (almost) trivial.

Example 2.1 The factorial language $F = F(G)$ is generated by a finite set G of prohibited factors. Then the minimal letter density $\rho_a(F)$ is rational and equal to the minimal density of the letter a over all cycles (accessible from the starting vertex) in the transition graph of language $F(G)$. (For transition graphs of factorial languages see Rosaz [6].)

Example 2.2 Let $M = \{0, 1\}$, and let ξ be a real number with $\xi \in (0; 1)$. Let F be the set of all finite factors of a standard Sturmian word $(a_1 a_2 \cdots)$ where $a_i = \lfloor (i+1)\xi \rfloor - \lfloor i\xi \rfloor$, $i = 1, 2, \ldots$. Then any infinite word in F^ω has density ξ. So, $\rho_1(F) = \xi$.

Example 2.3 Let $M = \{a, b\}$ and let F be the set of all overlap-free binary words (i. e., words that do not contain a factor w that has the form $w = v_1 v_2 c$ where c is the first letter of the word v_1). Restivo and Salemi [5] proved that any infinite overlap-free binary word is a concatenation of factors (ab) and (ba) with a preperiod of one or two symbols. It follows that $\rho_a(F) = \rho_b(F) = 1/2$.

Example 2.4 Infinite square-free words on the alphabet M (i. e., words that do not contain a factor w that has the form $w = vv$). It is obvious that if $|M| = 2$ then there are no infinite square-free words over alphabet M. There exist infinite square-free words on the ternary alphabet. A. Thue was the first to construct an example of such a word [8]. Therefore, if $|M| \geq 4$ we can construct an infinite square-free word over the alphabet $M \setminus \{a\}$. Consequently, $\rho_a(F) = 0$. Thus, the only interesting case in this respect is $|M| = 3$.

3 Lower bounds for the minimal letter density in ternary square-free words

In what follows F denotes the set of all ternary square-free words. The technique used to obtain the results given in this section was developed in Section 1. In the following table we give calculated values of numbers $l(\mathcal{A}_a^-(\xi-))$ and $l(\mathcal{A}_a^-(\xi))$ for "critical" ξ (i. e., for ξ such that these numbers differ). In our computer search we used the standard backtracking technique. For $\xi > 39/142$ we did not calculate all "critical" values of ξ because of the increasing of the required computer time.

Theorem 3.1 $l(\mathcal{A}_a^-(1780/6481-)) = 17312$.

The last result took near 40 hours on a Pentium, 166 MHz.

Corollary 3.1 *Let F be the set of ternary square-free words. Then $\rho_a(F) \geq 1780/6481 = 0.274648\cdots$ for all letters a.*

4 Upper bound

The most natural way to prove an upper bound for the minimal letter density is to construct a concrete word. As a result the letter density in this word will be a desired upper bound.

One of the main ways for constructing concrete infinite words is to use expansive morphisms. We consider morphisms of the form $h : M^* \to M^*$. In our case $M = \{a, b, c\}$. For $d \in M$ the infinite word $h^*(d)$ is generated by the infinite sequence of its prefixes

$$d, h(d), h(h(d)), h(h(h(d))), \dots \ .$$

A morphism h is called *square-free* if $h(w)$ is square-free whenever w is square-free. If h is a square-free morphism then, obviously, for any letter $d \in M$ the word $h^*(d)$ will be square-free. If for any letter $m \in M$ we have $\rho_a(h(m)) = \xi$ then, obviously, $\rho_a(h^*(d)) = \xi$ too. The words $h(m)$ are finite, therefore here $\xi = \frac{p}{q}$ is rational. Thus, the simplest way is to try to construct a morphism where images of all letters consist of fragments of lengths q that contain the letter a exactly p times for some positive integers p and q. The problem is how to choose p and q? Here we give an empirical method of selecting good parameters p and q.

Let $\xi = \frac{p}{q}$ be a rational number. Define

$$\mathcal{A}_a^-(\xi*) = \{w \in F \,|\, \forall \text{ prefixes } u \text{ of } w : \ \rho_a(u) < \xi \text{ and if } |u| = nq, n \in \mathbf{N}, \text{ then } \rho_a(u) = \xi\}.$$

For a given rational ξ we search an (infinite) word in the set $\mathcal{A}_a^-(\xi*)$ by the usual backtracking technique. In many cases we obtain in a short time that the set $\mathcal{A}_a^-(\xi*)$ is finite. Thus, we cannot apply the proposed method for the construction of a morphism. If the length of the maximal found prefix increases with stable high speed then we do an empirical conclusion that a morphism with proportion p to q can exist. If the length of the maximal found prefix increases very slowly we conclude that probably such a morphism does not exist.

This empirical method can be applied to the problem of minimal letter density in any factorial language. At first, we tried it for ternary square-free words. We obtained very strong empirical confirmation for the ratio 64/233. The set $\mathcal{A}_a^-(64/233*)$ contains only 10 words of length 233 (5 up to replacing $b \leftrightarrow c$). Combining these words we tried to construct a square-free morphism. We used the following test of Bean, Ehrenfeucht, and McNulty [1] that guarantees that a morphism is square-free:

> **<u>If</u>**
>
> (0) $h(w)$ is square-free whenever w is a word on M which is square-free and of length not greater than three,
>
> and
>
> (1) $a = b$ whenever $a, b \in M$ with $h(a)$ a subword of $h(b)$
>
> **<u>then</u>**
>
> $h(u)$ is square-free whenever u is a square-free word on M.

In our case it is sufficient to check that
(1) $h(a)$, $h(b)$ and $h(c)$ are not factors of one another,
(0) the words

$$\begin{array}{lll} h(a)h(b)h(a) & h(b)h(a)h(b) & h(c)h(a)h(b) \\ h(a)h(b)h(c) & h(b)h(a)h(c) & h(c)h(a)h(c) \\ h(a)h(c)h(a) & h(b)h(c)h(a) & h(c)h(b)h(a) \\ h(a)h(c)h(b) & h(b)h(c)h(b) & h(c)h(b)h(c) \end{array}$$

are square-free.

The desired morphism was constructed. We give it here. Denote

$A = bcbacbcabcbabcacbcabcbacbcacbabcbacbcabcbabcacbabcbacbcacbabcacbcabcbacbcacb$

$bacbcabcbabcacbabcbacbcacbabcacbcabcbacbcacbabcbacbcabcbabcacbcabcbacbcabacba$

(the words B' and D' can be derived from B and D respectively by replacing $b \leftrightarrow c$).

The constructed morphism h is

$$h(a) = BA$$
$$h(b) = BDB'D'$$
$$h(c) = BCB'D'$$

As a result of this construction we conclude that

Theorem 4.1 *Let F be the set of ternary square-free words. Then $\rho_a(F) \leq 64/233 = 0.274678\cdots$ for all letters a.*

In combination with the lower bound given in Corollary 4.1 we have

Theorem 4.2 *Let F be the set of ternary square-free words. Then $0.274648\cdots = 1780/6481 \leq \rho_a(F) \leq 64/233 = 0.274678\cdots$ for all letters a.*

Thus, $\rho_a(F) = 0.2746\cdots$.

Abstract. Arithmetic properties of integer sequences counting periodic points are studied, and applied to the case of linear recurrence sequences, Bernoulli numerators, and Bernoulli denominators.

1. Introduction

An existing dialogue between number theory and dynamical systems is advanced. A combinatorial device gives necessary and sufficient conditions for a sequence of non-negative integers to count the periodic points in a dynamical system. This is applied to study linear recurrence sequences which count periodic points. Instances where the p-parts of an integer sequence themselves count periodic points are studied. The Mersenne sequence provides one example, and the denominators of the Bernoulli numbers provide another. The methods give a dynamical interpretation of many classical congruences such as Euler-Fermat for matrices, and suggest the same for the classical Kummer congruences satisfied by the Bernoulli numbers.

Let X denote a set, and $T : X \to X$ a map. An element $x \in X$ is a periodic point of period $n \in \mathbb{N}$ if it is fixed under T^n, that is $T^n(x) = x$. Let $\mathrm{Per}_n(T)$ denote the set of points of period n under T. Following [13], call a sequence $u = (u_n)_{n\geq 1}$ of non-negative integers realizable if there is a set X and a map $T : X \to X$ such that $u_n = |\mathrm{Per}_n(T)|$.

This subject is example-driven so we begin our account with several of these. Throughout, examples will be referenced as they appear in the Encyclopedia of Integer Sequences.

Example 1.1. (1) Let $M_n = 2^n - 1, n \geq 1$ denote the n-th term of the Mersenne sequence A000225. This sequence is of interest in number theory because it is conjectured to contain infinitely many prime terms, and in dynamics because it counts the periodic points in the simplest expanding dynamical system. Let

$$\mathbb{S}^1 = \{z \in \mathbb{C} \mid |z| = 1\}$$

denote the complex unit circle. Then the map $T : \mathbb{S}^1 \to \mathbb{S}^1$, $T(z) = z^2$, has $|\mathrm{Per}_n(T)| = M_n$.

(2) Let L_n denote the n-th term of the Lucas sequence A000204. Let X denote the set of all doubly-infinite strings of 0's and 1's in which every 0 is followed by a 1, and let $T : X \to X$ be the left shift defined by $(Tx)_n = x_{n+1}$. Then $|\operatorname{Per}_n(T)| = L_n$.

(3) The Lehmer-Pierce sequences (generalizing the Mersenne sequence; see [4]) also arise in counting periodic points. Let $f(x)$ denote a monic, integral polynomial with degree $d \geq 1$ and roots $\alpha_1, \ldots, \alpha_d$. Define

$$\Delta_n(f) = \prod_i |\alpha_i^n - 1|,$$

which is non-zero for $n \geq 1$ under the assumption that no α_i is a root of unity. When $f(x) = x - 2$, we obtain $\Delta_n(f) = M_n$. Sequences of the form $(\Delta_n(f))$ were studied by Pierce and Lehmer with a view to understanding the special form of their factors, in the hope of using them to produce large primes. One such, is sequence A001945 corresponding to $f(x) = x^3 - x - 1$. In dynamics they arise as sequences of periodic points for toral endomorphisms: Let $X = \mathbb{T}^d$ denote the d-dimensional additive torus. The companion matrix A_f of f acts on X by multiplication mod 1, $T(x) = A_f x \bmod 1$. It requires a little thought to check that $|\operatorname{Per}_n(T)| = \Delta_n(f)$ under the same *ergodicity* condition that no α_i is a root of unity (see [4]). Notice that the Lehmer-Pierce sequences are the absolute values of integer sequences which could have mixed signs.

The next two examples illuminate the same issue of signed sequences whose absolute value counts periodic points.

(4) The Jacobsthal-Lucas sequence A014551 $R_n = |(-2)^n - 1|$ counts points of period n for the map $z \mapsto z^{-2}$ on $\mathbb{S}^1$.

(5) The sequence $S_n = |2^n + (-3)^n|$ counts periodic points in a certain continuous automorphism of a 1-dimensional solenoid, see [3] or [10].

(6) For $a \geq 1$, the shift map T on $\{0, 1, \ldots, a-1\}^{\mathbb{Z}}$ has $|\operatorname{Per}_n(T)| = a^n$.

(7) If B denotes a square matrix with non-negative integral entries then $(\operatorname{trace}(B^n))$ is a realizable sequence. To see this, let G_B be the labelled graph with adjacency matrix B and T_B the edge-shift on the set of labels of infinite paths on G_B. Then the number of points of period n for this system is $\operatorname{trace}(B^n)$ (see [11] for the details).

The sequences above are realizable by continuous maps of compact spaces; it turns out that any realizable sequence is in fact realizable by such a map.

It is natural to ask what is required of a sequence in order that it be realizable. For example, could the Fibonacci sequence A000045, the more illustrious cousin of the Lucas sequence, be realized in this way? The answer is no, and a simple proof will follow in Section 3. In fact a sequence of non-negative integers satisfying the Fibonacci recurrence is realizable if and only if it is a non-negative integer multiple of the Lucas sequence (see [13], [14], [15] and Theorem 2.1 below). However, we will see in Theorem 2.6 that in a precise sense, the Fibonacci sequence is semi-realizable.

2. Statements of Results

If $u = (u_n)$ is any sequence of integers, then it is reasonable to ask if the sequence $|u| = (|u_n|)$ of absolute values is realizable. For example, the sequence $(1, -3, 4, -7, \ldots)$ is a signed

linear recurrence sequence whose absolute values are realizable. A signed sequence u will also be called realizable if $|u|$ is realizable.

Theorem 2.1 recasts [14, Theorem 2.5], concerning realizable binary linear recurrence sequences, in a form that generalizes. The definitions are standard but they will be recalled later. Recall that the $\mathbb{C}$-space of all solutions of a binary recurrence relation has dimension 2. The *realizable subspace* is the subspace spanned by the realizable solutions. Thus, for the Fibonacci recurrence, the realizable subspace has dimension 1 and is spanned by the Lucas sequence.

Theorem 2.1. *Let Δ denote the discriminant of the characteristic polynomial associated to a non-degenerate binary recurrence relation. Then the realizable subspace has*

1. *dimension 0 if $\Delta < 0$,*
2. *dimension 1 if $\Delta = 0$ or $\Delta > 0$ and non-square,*
3. *dimension 2 if $\Delta > 0$ is a square.*

Example 2.2. (cf. [14, Example 2.6(2)]) As an example of the third condition, consider the recurrence relation

$$u_{n+2} = 3u_{n+1} - 2u_n, \tag{1}$$

which is satisfied by the Mersenne sequence. The recurrence sequences $a2^n + b$ with $a, b \in \mathbb{N}$ all satisfy (1) and are realizable — see Corollary 3.2.

Theorem 2.1 is proved in [14] using essentially quadratic methods — but it surely has a generalization to higher degree, characterizing the realizable subspace in terms of the factorization of the characteristic polynomial of the recurrence. The second theorem is a partial result in that direction, giving a restriction on the dimension of the realizable subspace under the assumption that the characteristic polynomial has a dominant root.

Theorem 2.3. *Let f denote the characteristic polynomial of a non-degenerate linear recurrence sequence with integer coefficients. If f is separable, with ℓ irreducible factors and a dominant root then the dimension of the realizable subspace cannot exceed ℓ. If $f(0) \neq 0$ then equality holds if either the dominant root is not less than the sum of the absolute values of the other roots or the dominant root is strictly greater than the sum of the absolute values of its conjugates.*

It is not clear if there is an exact result but the deep result of Kim, Ormes and Roush [8] on the Spectral Conjecture of Boyle and Handelman [1] gives a checkable criterion for a given linear recurrence sequence to be realized *by an irreducible subshift of finite type*.

Example 2.4. Consider the sequences which satisfy the Tribonacci relation

$$u_{n+3} = u_{n+2} + u_{n+1} + u_n. \tag{2}$$

The sequence A001644 satisfies (2) and is realizable, since it is the sequence $\left(\mathrm{trace}(A_f^n)\right)$, where A_f is the companion matrix to $f(x) = x^3 - x^2 - x - 1$. Theorem 2.3 says that any realizable sequence which satisfies (2) is a multiple of this one.

Example 2.5. Suppose g denotes a polynomial with $\ell - 1$ distinct irreducible factors (possibly repeated). For an integer K, consider the linear recurrence relation with characteristic polynomial

$$f(x) = (x - K)g(x).$$

For all sufficiently large K, f has ℓ distinct irreducible factors and the realizable subspace has dimension ℓ.

The third theorem consists of a triple of examples. Given a sequence u and a prime p, write $[u_n]_p$ for the p-part of u_n. Notice that $[u]_p$ is always non-negative. A sequence u is *locally realizable at* p if $[u]_p$ is itself realizable, and is *everywhere locally realizable* if it is locally realizable at p for all primes p. If a sequence is everywhere locally realizable and non-negative then it is realizable by Corollary 3.2 below. Moss has shown [12] that the converse is true for any endomorphism of a locally nilpotent group.

Consider the Bernoulli numbers B, defined by the relation

$$\frac{t}{e^t - 1} = \sum_{n=0}^{\infty} B_n \frac{t^n}{n!};$$

$B_n \in \mathbb{Q}$ for all n, and $B_n = 0$ for all odd $n > 1$.

Theorem 2.6. *Any Lehmer–Pierce sequence is everywhere locally realizable, and hence realizable. The Fibonacci sequence is locally realizable at primes $\equiv \pm 1$ modulo 5. Let b_n denote the denominator of B_{2n} for $n \geq 1$. Then $b = (b_n)$ is everywhere locally realizable, and hence realizable.*

The sequence b is A002445, a much-studied sequence. The maps in Theorem 2.6 are endomorphisms of groups. Theorem 2.6 and Lemma 3.1 suggest a dynamical interpretation of composite versions of the classical Kummer congruences; see Section 4 below.

3. Combinatorics of periodic points

As pointed out in [14, Example 2.2(1)], the Fibonacci sequence is not realizable. No map can have 1 fixed point and 2 points of period 3 — the image under the map of the non-fixed point of period 3 would have to be a distinct non-fixed point of period 3, and there are no others. More generally, for any prime p, the number of non-fixed points of period p must be divisible by p because their orbits occur in cycles of length p. From this kind of reasoning, the following characterization emerges (see [14, Lemma 2.1]).

Lemma 3.1. *Let u be a sequence of non-negative integers, and let $u * \mu$ denote the Dirichlet convolution of u with the Möbius function μ. Then u is realizable if and only if $(u * \mu)_n \equiv 0$ mod n and $(u * \mu)_n \geq 0$ for all $n \geq 1$.*

Corollary 3.2. *The sum and product of two realizable sequences are both realizable.*

Proof. This may be seen either using elementary properties of the Dirichlet convolution or using the realizing maps: if u and v are realizable, then the Cartesian product of the realizing maps realizes $(u_n v_n)$, while the disjoint union realizes $(u_n + v_n)$. □

Notice that if $n = p^r$, for a prime p and $r > 0$ an integer, Lemma 3.1 requires that

$$u_{p^r} \equiv u_{p^{r-1}} \mod p^r \tag{3}$$

for any realizable sequence u.

Corollary 3.3. *Let a denote a positive integer and let p and r be as above. Then*

$$a^{p^r} \equiv a^{p^{r-1}} \mod p^r.$$

Proof. This is the statement of the Euler-Fermat Theorem; a dynamical proof applies (3) to Example 1.1(6). □

This kind of observation — that periodic points in full shifts give simple proofs of many elementary congruences — is folklore; indeed the paper [2] gives a rather complicated proof of Euler–Fermat using a dynamical system.

Lemma 3.1 does more with no additional effort. The following is a generalization of the Euler-Fermat Theorem for integral matrices which will be used in the proof of Theorem 2.1.

Corollary 3.4. *Let A denote a square matrix with integer entries and let p and r be as above. Then*

$$\operatorname{trace}(A^{p^r}) \equiv \operatorname{trace}(A^{p^{r-1}}) \mod p^r.$$

Proof. It is sufficient to assume A has non-negative entries, since any matrix has such a representative mod p^r. The result follows at once from Example 1.1(7). □

We now state the consequences of Lemma 3.1 in their most general form for matrix traces.

Corollary 3.5. *Let A denote a square matrix with integer entries and let A_n denote the sequence* $\operatorname{trace}(A^n)$. *Then for all $n \geq 1$*

$$\sum_{d|n} A_d \mu(n/d) \equiv 0 \mod n.$$

4. Proofs

Before the proof of Theorem 2.1, we begin with some notation (for a lively account of the general properties of linear recurrence sequences, see [16]). Let u be a binary recurrence sequence. This means that u_1 and u_2 are given as initial values, with all subsequent terms defined by a recurrence relation

$$u_{n+2} = Bu_{n+1} - Cu_n. \tag{4}$$

The polynomial $f(x) = x^2 - Bx + C$ is the *characteristic polynomial* of the recurrence relation. Write

$$A_f = \begin{pmatrix} 0 & 1 \\ -C & B \end{pmatrix}$$

for the companion matrix of f. The zeros α_1 and α_2 of f, are the *characteristic roots* of the recurrence relation. The sequence is non-degenerate if α_1/α_2 is not a root of unity. The *discriminant* of the recurrence relation is $\Delta = B^2 - 4C$. The general solution of the recurrence relation is $u_n = (\gamma_1 + \gamma_2 n)\alpha_1^n$ if $\Delta = 0$, and $u_n = \gamma_1\alpha_1^n + \gamma_2\alpha_2^n$ if $\Delta \neq 0$.

Proof of Theorem 2.1. Assume first that $\Delta = 0$, and let p denote any prime which does not divide α_1 or γ_2. Then the congruence (3) is violated at $n = p$ unless $\gamma_2 = 0$. In that case, $|\gamma_1\alpha_1^n|$ is realizable and the space this generates is 1-dimensional.

If $\Delta > 0$ is a square, then the roots are rationals and, plainly, must be integers. We claim that for any integers γ_1 and γ_2, the sequence $|\gamma_1\alpha_1^n + \gamma_2\alpha_2^n|$ is realizable. In fact (up to multiplying and adding full shifts) this sequence counts the periodic points for an automorphism on a one-dimensional solenoid, see [4] or [10].

The two cases where $\Delta \neq 0$ is not a square are similar. Write $\alpha = s + t\sqrt{\Delta}$, with $s, t \in \mathbb{Q}$, for one of the roots of f and let $K = \mathbb{Q}(\alpha)$ denote the quadratic number field generated

by α. Write $\mathrm{T}_{K|\mathbb{Q}} : K \to \mathbb{Q}$ for the usual field trace. The general integral solution to the recurrence is $u_n = \mathrm{T}_{K|\mathbb{Q}}((a + b\sqrt{\Delta})\alpha^n)$, where a and b are both integers or both half-odd integers. Write $v_n = \mathrm{T}_{K|\mathbb{Q}}(a\alpha^n)$ and $w_n = \mathrm{T}_{K|\mathbb{Q}}(b\sqrt{\Delta}\alpha^n)$. Now $v_n = a\,\mathrm{trace}(A_f^n)$, where A_f denotes the companion matrix of f. Hence it satisfies $v_p \equiv v_1 \bmod p$ for all primes p by Corollary 3.4.

Let p denote any inert prime for K. The residue field is isomorphic to the field $\mathbb{F}_{p^2}$. Moreover, the non-trivial field isomorphism restricts to the Frobenius at the finite field level. Reducing mod p gives the congruence

$$\sqrt{\Delta}\alpha^p - \sqrt{\Delta}\alpha \equiv \sqrt{\Delta}\alpha - \sqrt{\Delta}\alpha^p \mod p.$$

Thus $w_p \equiv -w_1 \bmod p$ for all inert primes p. On the other hand, $v_p \equiv v_1 \bmod p$ for all inert primes p.

If $|u_n|$ is realizable then $|u_p| \equiv |u_1| \bmod p$ by (3). If $u_p \equiv -u_1 \bmod p$ for infinitely many primes p then $v_p + w_p \equiv v_1 - w_1 \equiv -v_1 - w_1 \bmod p$. We deduce that $p|v_1$ for infinitely primes and hence $v_1 = 2as = 0$. We cannot have $s = 0$ by the non-degeneracy, so $a = 0$. If $u_p \equiv u_1 \bmod p$ then, by a similar argument, we deduce that $bt = 0$. We cannot have $t = 0$ again, by the non-degeneracy so $b = 0$. This proves that when $\Delta \neq 0$ is not a square, the realizable subspace must have rank less than 2.

Suppose firstly that $\Delta > 0$. We will prove that the rank is precisely 1. In this case, there is a dominant root. If this root is positive then all the terms of u_n are positive. If the dominant term is negative then the sequence of absolute values agrees with the sequence obtained by replacing α by $-\alpha$ and the dominant root is now positive. In the recurrence relation (4) $C = \mathrm{N}_{K|\mathbb{Q}}(\alpha)$, the field norm, and $B = \mathrm{T}_{K|\mathbb{Q}}(\alpha)$. We are assuming $B > 0$. If $C < 0$ then the sequence $u_n = \mathrm{trace}(A_f^n)$ is realizable using Example 1.1(7), because the matrix A_f has non-negative entries. If $C > 0$ the matrix A_f may be conjugated to a matrix with non-negative entries (this leaves the sequence of traces invariant). To see this, let E denote the matrix

$$E = \begin{pmatrix} 1 & 0 \\ k & 1 \end{pmatrix}.$$

Then

$$E^{-1}A_fE = \begin{pmatrix} k & 1 \\ Bk - k^2 - C & B - k \end{pmatrix}.$$

If B is even, take $k = B/2$. Then the lower entries in $E^{-1}A_fE$ are $(B^2 - 4C)/4 = \Delta/4 > 0$ and $B/2 > 0$. If B is odd, take $k = (B+1)/2$. Then the lower entries are $(B^2 - 1 - 4C)/4 = (\Delta - 1)/4 \geq 0$ and $(B - 1)/2 \geq 0$. In both cases we have conjugated A_f to a matrix with non-negative entries.

Finally, we must show that when $\Delta < 0$, both sequences v_n and w_n are not realizable in absolute value. Assume $a \neq 0$, and then note that $v_1 = 2as \neq 0$ by the non-degeneracy assumption. For all primes p we have $v_p \equiv v_1$ by the remark above. Since the roots α_1 and α_2 are complex conjugates, $|\alpha_1| = |\alpha_2|$. Let $\beta = \frac{1}{2\pi}\arg(\alpha_1/\alpha_2)$; β is irrational by the non-degeneracy assumption. The sequence of fractional parts of $p\beta$, with p running through the primes, is dense in $(0, 1)$ (this was proved by Vinogradov [19]; see [18] for a modern treatment). It follows that there are infinitely many primes p for which $v_pv_1 < 0$. Therefore, if $|v_n|$ is realizable then it satisfies $v_p \equiv v_1 \bmod p$ and $-v_p \equiv v_1 \bmod p$ for infinitely many primes. We deduce that $v_1 = 0$ which is a contradiction. With w_n we may argue in a

similar way to obtain a contradiction to $w_1 \neq 0$. If $|w_n|$ is realizable then Lemma 3.1 says $|w_{p^2}| \equiv |w_p| \equiv |w_1|$ for all primes p. Arguing as before, $w_{p^2} \equiv w_1$ for both split and inert primes. However, the sequence $\{p^2\beta\}$, p running over the primes, is dense in $(0,1)$. (Again, this is due to Vinogradov in [19] or see [5] for a modern treatment. The general case of $\{F(p)\}$, where F is a polynomial can be found in [7].) We deduce that $w_{p^2}w_1 < 0$ for infinitely many primes. This means $w_{p^2} \equiv w_1 \bmod p$ and $w_{p^2} \equiv -w_1 \bmod p$ infinitely often. This forces $w_1 = 0$ — a contradiction.

Proof of Theorem 2.3. Let d denote the degree of f. In the first place we assume $\ell = 1$, thus f is irreducible. The irreducibility of f implies that the rational solutions of the recurrence are given by $u_n = \mathrm{T}_{K|\mathbb{Q}}(\gamma\alpha^n)$, where $K = \mathbb{Q}(\alpha)$, and $\gamma \in K$. We write $\gamma_i, \alpha_i, i = 1, \ldots, d$ for the algebraic conjugates of γ and α. The dominant root hypothesis says, after re-labelling, $|\alpha_1| > |\alpha_i|$ for $i = 2, \ldots, d$. We will show that if u is realizable then $\gamma \in \mathbb{Q}$.

Let p denote any inert prime. If p is sufficiently large, the dominant root hypothesis guarantees that $u_p, \ldots, u_{p^d}$ will all have the same sign. Using Lemma 3.1 several times, we deduce that

$$u_p \equiv u_{p^2} \equiv \cdots \equiv u_{p^d} \equiv \pm u_1 \mod p.$$

Therefore $u_p + \cdots + u_{p^d} \equiv \pm d u_1 \bmod p$, the sign depending upon the sign of u_1. However,

$$u_p + \cdots + u_{p^d} \equiv \mathrm{T}_{K|\mathbb{Q}}(\gamma)\,\mathrm{T}_{K|\mathbb{Q}}(\alpha) \mod p.$$

We deduce a fundamental congruence

$$\mathrm{T}_{K|\mathbb{Q}}(\gamma)\,\mathrm{T}_{K|\mathbb{Q}}(\alpha) \equiv \pm d\,\mathrm{T}_{K|\mathbb{Q}}(\gamma\alpha) \mod p.$$

Since this holds for infinitely many primes p, the congruence is actually an equality,

$$\mathrm{T}_{K|\mathbb{Q}}(\gamma)\,\mathrm{T}_{K|\mathbb{Q}}(\alpha) = \pm d\,\mathrm{T}_{K|\mathbb{Q}}(\gamma\alpha). \tag{5}$$

The next step comes with the observation that if u_n is realizable then u_{rn} is realizable for every $r \geq 1$. Thus equation (5) now reads

$$\mathrm{T}_{K|\mathbb{Q}}(\gamma)\,\mathrm{T}_{K|\mathbb{Q}}(\alpha^r) = \pm d\,\mathrm{T}_{K|\mathbb{Q}}(\gamma\alpha^r). \tag{6}$$

Dividing equation (6) by α_1^r and letting $r \to \infty$ we obtain the equation

$$\mathrm{T}_{K|\mathbb{Q}}(\gamma) = \pm d\gamma_1.$$

This means that one conjugate of γ is rational and hence γ is rational.

The end of the proof in the case $\ell = 1$ can be re-worked in a way that makes it more amenable to generalization. The trace is a $\mathbb{Q}$-linear map on K so its kernel has rank $d-1$. Thus every element γ of K can be written $q + \gamma_0$ where $q \in \mathbb{Q}$ and $\mathrm{T}_{K|\mathbb{Q}}(\gamma_0) = 0$. Noting that $\mathrm{T}_{K|\mathbb{Q}}(q) = dq$ and cancelling d, this simply means equation (6) can be written

$$u_r = \pm q\,\mathrm{T}_{K|\mathbb{Q}}(\alpha^r),$$

for all $r \geq 1$ confirming that the realizable subspace has rank ≤ 1.

The general case is similar. Each of the irreducible factors of f generates a number field $K_j, j = 1, \ldots, \ell$ of degree $d_j = [K_j : \mathbb{Q}]$. The solutions of the recurrence look like

$$u_n = \sum_{j=1}^{\ell} \mathrm{T}_{K_j|\mathbb{Q}}(\gamma_j\alpha_j^n),$$

where each $\gamma_j \in K_j$. Let L denote the compositum of the K_j. Using the inert primes of L and noting that each is inert in each K_j, we deduce an equation

$$\sum_{j=1}^{\ell} \frac{d}{d_j} \operatorname{T}_{K_j|\mathbb{Q}}(\gamma_j) \operatorname{T}_{K_j|\mathbb{Q}}(\alpha_j) = \pm d \sum_{j=1}^{\ell} \operatorname{T}_{K_j|\mathbb{Q}}(\gamma_j \alpha_j). \tag{7}$$

As before, replace α_j by α_j^r, and cancel d so that

$$u_r = \pm \sum_{j=1}^{\ell} \frac{1}{d_j} \operatorname{T}_{K_j|\mathbb{Q}}(\gamma_j) \operatorname{T}_{K_j|\mathbb{Q}}(\alpha_j^r)$$

Each γ_j can be written $\gamma_j = q_j + \gamma_{0j}$, where $\operatorname{T}_{K_j|\mathbb{Q}}(\gamma_{0j}) = 0$. Noting that $\operatorname{T}_{K_j|\mathbb{Q}}(q_j) = d_j q_j$ we deduce that

$$u_r = \pm \sum_{j=1}^{\ell} q_j \operatorname{T}_{K_j|\mathbb{Q}}(\alpha_j^r)$$

which proves that the realizable subspace has rank $\leq \ell$.

Finally, show that equality holds in the two cases stated. Write $u_n^{(j)} = \operatorname{T}_{K_j|\mathbb{Q}}(\alpha_j^n)$, which is not identically zero because no $\alpha_j = 0$. Each sequence $u_n^{(j)}$ satisfies the congruence part of Lemma 3.1 and hence any $\mathbb{Z}$-linear combination also satisfies the congruence. This is because $u_n^{(j)}$ is identical to $\operatorname{trace}(A_{f_j}^n)$, where A_{f_j} denotes the companion matrix for f_j - hence we can invoke Corollary 3.5. To obtain l linearly independent realizable sequences, suppose α_1 is the dominant root and take $u_n^{(1)}$ together with $u_n^{(1)} + u_n^{(j)}$ for $j = 2, \ldots, l$. The non-negativity part of Lemma 3.1 follows from the condition on the dominant root. For the second case, a similar argument shows that for sufficiently large $M > 0$, the independent sequences $u_n^{(1)}$ and $M u_n^{(1)} + u_n^{(j)}$ are realizable.

Proof of Theorem 2.6. It is sufficient to construct local maps $T_p : X_p \to X_p$ for each prime p. Then Corollary 3.2 guarantees a global realization by defining

$$T = \prod_p T_p \text{ on } X = \prod_p X_p.$$

If the maps T_p are group endomorphisms then the map T is a group endomorphism.

As motivation, consider the Mersenne sequence. For each prime p, let $\mathbb{U}_p \subset \mathbb{S}^1$ denote the group of all pth power roots of unity. Define the local endomorphism $S_p : x \mapsto x^2$ on $\mathbb{U}_p$. Then $|\operatorname{Per}_n(S_p)| = [2^n - 1]_p$ so S_p gives a local realization of the Mersenne sequence. Using the same method of proof, we can easily verify the claim about the Fibonacci sequence. Let F_n denote the n-th term and let X denote the group of all p-th power roots of 1. This is naturally a $\mathbb{Z}_p$-module. Let u denote the golden-mean, thought of as lying in $\mathbb{Z}_p$ by the congruence property on p. Then the map $x \mapsto x^{-u^2}$ has precisely $[F_n]_p$ points of period p.

An alternative proof in the Mersenne case uses the S-integer dynamical systems from [3]: for each prime p, define T_p to be the automorphism dual to $x \mapsto 2x$ on $\mathbb{Z}_{(p)}$ (the localization at p). Then by [3],

$$|\operatorname{Per}_n(T_p)| = \prod_{q \leq \infty; q \neq p} |2^n - 1|_q = [2^n - 1]_p$$

by the product formula. This approach gives a convenient proof for Lehmer-Pierce sequences in general. We may assume that the polynomial f is irreducible; let $K = \mathbb{Q}(\xi)$ for some zero of f. Then for each prime p, let S comprise all places of K expect those lying above p, and let T_p be the S-integer map dual to $x \mapsto \xi x$ on the ring of S-integers in K. Then by the product formula

$$|\operatorname{Per}_n(T_p)| = \Big(\prod_{v|p} |\xi^n - 1|_v\Big)^{-1} = [\Delta_n(f)]_p$$

as required.

For the Bernoulli denominators, define $X_p = \mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$. For $p = 2$ define T_p to be the identity. For $p > 2$, let g_p denote an element of (multiplicative) order $(p-1)/2$. Define $T_p : X_p \to X_p$ to be the endomorphism $T_p(x) = g_p x \bmod p$. Plainly $|\operatorname{Per}_n(T_p)| = p$ if and only if $p - 1|2n$; for all other n, $|\operatorname{Per}_n(T_p)| = 1$. The Clausen von Staudt Theorem ([6], [9]) states that

$$B_{2n} + \sum \frac{1}{p} \in \mathbb{Z},$$

where the sum ranges over primes p for which $p - 1|2n$. Thus $|\operatorname{Per}_n(T_p)| = \max\{1, |B_{2n}|_p\}$ and this shows the local realizability of the Bernoulli denominators.

5. Epilogue

A result similar to the one in Theorem 2.6 for the Fibonacci sequence can be proved for any binary linear recurrence sequence, using the primes which split in the corresponding quadratic field.

Using the same ideas as in the proof of Theorem 2.6 one can prove that the sequence A006953, the denominators of $B_{2n}/2n$, is everywhere locally realizable. A much more subtle result, due to Moss [12], is that the sequence A001067, the numerators of $B_{2n}/2n$, is a realizable sequence that is not locally realizable exactly at the irregular primes A000928. Taking these remarks together with $n = p^r$ in Lemma 3.1, suggests a dynamical interpretation of the Kummer congruences. These are stated now, for a proof see [9].

Theorem 5.1. *If p denotes a prime and $p - 1$ does not divide n then $n \equiv n'$ mod $(p-1)p^r$ implies*

$$(1 - p^{n-1})\frac{B_n}{n} \equiv (1 - p^{n'-1})\frac{B_{n'}}{n'} \mod p^{r+1}.$$

Finally, experimental evidence suggests the sequence A006863, the denominators of $B_{2n}/4n$ forms a realizable sequence that is not locally realizable at the primes $2, 3, 5, 7, 11, 13$ but seems to be locally realizable for all large primes.

Abstract

In this paper it is shown that for $n \equiv 0$ or $3 \pmod 4$, the middle term $S(n)$ in the expansion of the polynomial $(1+x)(1+x^2)\cdots(1+x^n)$ occurs naturally when one analyzes when a discontinuous product of trigonometric functions is a derivative of a function. This number also represents the number of partitions of $T_n/2 = n(n+1)/4$, (where T_n is the nth triangular number) into distinct parts less than or equal to n. It is proved in a constructive way that $S(n) \geq 6S(n-4)$ for every $n \geq 8$, and an

asymptotic evaluation of $S(n)^{1/n}$ is obtained as a consequence of the unimodality of the coefficients of this polynomial. Also an integral expression of $S(n)$ is deduced.

1 Notation and preliminary results

In a paper of Andrica [3] the following necessary and sufficient condition that some product of derivatives is also a derivative is deduced:

Theorem 1.1 *Let $n_1, \ldots, n_k \geq 0$ be integers with $n_1 + \ldots + n_k \geq 1$ and let $\alpha_1, \ldots, \alpha_k$ be real numbers different from zero. The function $f_{n_1,\ldots,n_k}^{\alpha_1,\ldots,\alpha_k} : \mathbb{R} \to \mathbb{R}$, defined by*

$$f_{n_1,\ldots,n_k}^{\alpha_1,\ldots,\alpha_k}(x) = \begin{cases} \cos^{n_1}(\alpha_1/x) \cdots \cos^{n_k}(\alpha_k/x), & \text{if } x \neq 0; \\ \alpha, & \text{if } x = 0; \end{cases}$$

is a derivative if and only if

$$\alpha = \frac{1}{2^{n_1+\ldots+n_k}} S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k),$$

where $S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k)$ is the number of all choices of signs $+$ and $-$ such that

$$\underbrace{\pm\alpha_1 \pm \ldots \pm \alpha_1}_{n_1 \text{ times}} \underbrace{\pm\alpha_2 \pm \ldots \pm \alpha_2}_{n_2 \text{ times}} \pm \ldots \underbrace{\pm\alpha_k \pm \ldots \pm \alpha_k}_{n_k \text{ times}} = 0. \tag{1}$$

Note that this theorem extends one previously published in [2].

We shall present another combinatorial interpretations of the numbers

$$S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k)$$

and an integral representation, while the last section is devoted to the sequence $S(n) = S(\underbrace{1, \ldots, 1}_{n \text{ times}}; 1, 2, 3, \ldots, n)$ for $n \geq 1$.

Let M be a multiset of type $\alpha_1^{n_1}\alpha_2^{n_2}\ldots\alpha_k^{n_k}$, i.e., a multiset containing α_i with multiplicity n_i for every $1 \leq i \leq k$. It is clear that $S(n_1, \ldots, n_k; \alpha_1, \ldots \alpha_k)$ is the number of ordered partitions having equal sums of M, i.e., of ordered pairs (C_1, C_2) such that $C_1 \cup C_2 = M$, $C_1 \cap C_2 = \emptyset$ and $\sum_{x \in C_1} x = \sum_{y \in C_2} y = \frac{1}{2}\sum_{i=1}^{k} n_i\alpha_i$. Indeed, there exists a bijection between the set of all choices of $+$ or $-$ signs in (1) and the set of all ordered partitions with equal sums of M defined as follows: We put α_i from (1) in C_1 if its sign is $+$ and in C_2 otherwise.

It is also clear that $S(n_1, \ldots, n_k; \alpha_1 \ldots, \alpha_k)$ is the term not depending on z in the expansion

$$F(z) = \left(z^{\alpha_1} + \frac{1}{z^{\alpha_1}}\right)^{n_1} \left(z^{\alpha_2} + \frac{1}{z^{\alpha_2}}\right)^{n_2} \ldots \left(z^{\alpha_k} + \frac{1}{z^{\alpha_k}}\right)^{n_k}. \tag{2}$$

Wilf [10] outlines a proof that for $n_1 = n_2 = \ldots = n_k = 1$, the coefficient of z^n in $F(z)$ represents the number of ways of choosing $+$ or $-$ signs such that $\pm\alpha_1 \pm \alpha_2 \pm \ldots \pm \alpha_k = n$. If $\alpha_1, \ldots, \alpha_k$ are positive integers, from (2) one gets

$$F(z) = S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k) + \sum_{\alpha \neq 0} a_\alpha z^\alpha, \tag{3}$$

where the sum has only a finite number of terms and α and a_α are integers. By substituting $z = \cos t + i \sin t$, $t \in \mathbb{R}$ in (3) one deduces

$$2^{n_1+\ldots+n_k} \prod_{j=1}^{k} (\cos \alpha_j t)^{n_j} = S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k) + \sum_{\alpha \neq 0} a_\alpha (\cos \alpha t + i \sin \alpha t)$$

By integration on $[0, 2\pi]$ we find the following integral expression of $S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k)$:

$$S(n_1, \ldots, n_k; \alpha_1, \ldots, \alpha_k) = \frac{2^{n_1+\ldots+n_k}}{2\pi} \int_0^{2\pi} (\cos \alpha_1 t)^{n_1} \cdots (\cos \alpha_k t)^{n_k} dt.$$

2 A particular case and its connection with polynomial unimodality

An interesting particular case is obtained for $n_1 = n_2 = \ldots = n_k = 1$ and $\alpha_i = i$ for every $1 \leq i \leq k$. In this case $S(n)$ is the number of ways of choosing $+$ and $-$ signs such that $\pm 1 \pm 2 \pm \ldots \pm n = 0$. Since now $M = \{1, 2, \ldots, n\}$ has sum $T_n = n(n+1)/2$ and every class of an ordered bipartition of M must have sum $T_n/2$, it follows that $S(n) = 0$ for $n \equiv 1$ or $2 \pmod 4$ and $S(n) \neq 0$ for $n \equiv 0$ or $3 \pmod 4$. The following theorem proposes several equivalent definitions of the sequence $S(n)$ for $n \geq 1$.

Theorem 2.1 *For every $n \geq 1$ the following properties are equivalent:*

(i) $S(n)$ is the number of choices of $+$ and $-$ signs such that $\pm 1 \pm 2 \pm \ldots \pm n = 0$;

(ii) $S(n)$ is the number of ordered bipartitions into classes having equal sums of $\{1, 2, \ldots, n\}$;

(iii) $S(n)$ is the term not depending on x in the expansion of

$$\left(x + \frac{1}{x}\right)\left(x^2 + \frac{1}{x^2}\right) \ldots \left(x^n + \frac{1}{x^n}\right);$$

(iv) $S(n)$ is the number of partitions of $T_n/2$ into distinct parts, less than or equal to n, if $n \equiv 0$ or $3 \pmod 4$, and $S(n) = 0$ otherwise;

(v) $S(n)$ is the number of distinct subsets of $\{1, \ldots, n\}$ whose elements sum to $T_n/2$ if $n \equiv 0$ or $3 \pmod 4$, and $S(n) = 0$ if $n \equiv 1$ or $2 \pmod 4$;

(vi) $S(n)$ is the coefficient of $x^{T_n/2}$ in the polynomial $G_n(x) = (1+x)(1+x^2)\ldots(1+x^n)$ when $n \equiv 0$ or $3 \pmod 4$, and $S(n) = 0$ otherwise;

(vii)

$$S(n) = \frac{2^{n-1}}{\pi} \int_0^{2\pi} \cos t \cos 2t \cdots \cos nt \, dt;$$

(viii) $S(n)/2^n$ *is the unique real number* α *having the property that the function* $f : \mathbb{R} \to \mathbb{R}$, *defined by*

$$f(x) = \begin{cases} \cos(1/x)\cos(2/x)\cdots\cos(n/x), & \text{if } x \neq 0; \\ \alpha, & \text{if } x = 0; \end{cases}$$

is a derivative.

Proof: Some equivalences are obvious or were shown in the general case. For example, the equivalence between (ii) and (v) is given by the bijection φ defined for every bipartition $M = C_1 \cup C_2$ such that $\sum_{x\in C_1} x = \sum_{y\in C_2} y$ by $\varphi(C_1 \cup C_2) = C_1 \subset M$. □

Let us denote

$$G_n(x) = (1+x)(1+x^2)\dots(1+x^n) = \sum_{i=0}^{T_n} G(n,i)x^i. \tag{4}$$

Note that the property that the coefficient of x^i in $G_n(x)$ is the number of distinct subsets of $\{1,\dots,n\}$ whose elements sum to i was used by Friedman and Keith [5] to deduce a necessary and sufficient condition for the existence of a basic (n,k) magic carpet. Stanley [9], using the "hard Lefschetz theorem" from algebraic geometry, proved that the posets $M(n)$ of all partitions of integers into distinct parts less than or equal to n are rank unimodal, by showing the existence of a chain decomposition for $M(n)$. This fact is equivalent to the unimodality of the polynomial $G_n(x)$, which implies that $S(n)$ is the maximum coefficient in the expansion of $G_n(x)$ for $n \equiv 0$ or $3 \pmod 4$. Stanley's proof was subsequently simplified by Proctor [6].

The property of symmetry of the coefficients in (4), namely $G(n,i) = G(n,T_n - i)$ for every $0 \le i \le T_n$ was pointed out by Friedman and Keith[5]; they also found the recurrence $G(n,i) = G(n-1,i) + G(n-1,i-n)$. This latter recurrence, which is a consequence of the identity $G_n(x) = G_{n-1}(x)(1+x^n)$, allows us to compute any finite submatrix of the numbers $G(n,i)$ and thus the numbers $S(n) = G(n,T_n/2)$.

Some values of $S(n)$, starting with $n = 3$, are given in the following table:

n	$S(n)$	n	$S(n)$	n	$S(n)$	n	$S(n)$
3	2	13	0	23	99,820	33	0
4	2	14	0	24	187,692	34	0
5	0	15	722	25	0	35	221,653,776
6	0	16	1,314	26	0	36	425,363,952
7	8	17	0	27	1,265,204	37	0
8	14	18	0	28	2,399,784	38	0
9	0	19	8,220	29	0	39	3,025,553,180
10	0	20	15,272	30	0	40	5,830,034,720
11	70	21	0	31	16,547,220	41	0
12	124	22	0	32	31,592,878	42	0

and thus the terms different from zero form a subsequence of the sequence A025591 in Sloane [7].

Another recurrence satisfied by the numbers $G(n,i)$ is the following:

Lemma 2.2 *We have* $G(n,i) = \sum_{j\geq 0} G(n-1-j, i-n+j)$.

Proof: Let $\mathcal{P}(k,i)$ denote the set of partitions of i into distinct parts such that the maximum part is equal to k. It is clear that

$$G(n,i) = \left|\bigcup_{j\geq 0} \mathcal{P}(n-j,i)\right| = \sum_{j\geq 0} |\mathcal{P}(n-j,i)| = \sum_{j\geq 0} G(n-1-j, i-n+j).$$

Indeed, there is a bijection between the set of partitions of i into distinct parts such that the maximum part equals $n-j$ and the set of partitions of $i-n+j$ into distinct parts less than or equal to $n-1-j$, defined by deleting the maximum part, equal to $n-j$, in any partition in $\mathcal{P}(n-j,i)$. Hence $|\mathcal{P}(n-j,i)| = G(n-1-j, i-n+j)$. □

Theorem 2.3 *For any* $n \geq 8$ *we have* $S(n) \geq 6S(n-4)$.

Proof: For $n \leq 11$ this inequality is verified by inspection.

For $n \geq 12$ we shall propose a constructive proof yielding for any ordered partition of $\{1,\ldots,n-4\}$ in two classes C_1 and C_2 with equal sums six ordered partitions of $\{1,\ldots,n\}$ in two classes $\mathtt{C}'_1$ and $\mathtt{C}'_2$ having equal sums and all partitions generated will be distinct. Indeed, for any ordered bipartition with equal sums $\{1,\ldots,n-4\} = C_1 \cup C_2$ we can generate six ordered bipartitions with equal sums $\{1,\ldots,n\} = \mathtt{C}'_1 \cup \mathtt{C}'_2$ as follows:

(a) $\mathtt{C}'_1 = C_1 \cup \{n-3, n\}$ and $\mathtt{C}'_2 = C_2 \cup \{n-2, n-1\}$;

(b) $\mathtt{C}'_1 = C_1 \cup \{n-2, n-1\}$ and $\mathtt{C}'_2 = C_2 \cup \{n-3, n\}$;

(c) Without loss of generality suppose $1 \in C_1$. We define $\mathtt{C}''_1 = C_1 \backslash \{1\}$, $\mathtt{C}''_2 = C_2 \cup \{1\}$, $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n-2, n\}$ and $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n-3, n-1\}$;

(d) Without loss of generality suppose $2 \in C_1$. Now $\mathtt{C}''_1 = C_1 \backslash \{2\}$, $\mathtt{C}''_2 = C_2 \cup \{2\}$, $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n-1, n\}$, $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n-3, n-2\}$.

Case (e) is a little more complicated, but we will be able to do it by combining two simple transformations.

(e) Suppose $1 \in C_1$. If $n-4$ belongs to the same class, we define $\mathtt{C}''_1 = C_1 \backslash \{1, n-4\}$, $\mathtt{C}''_2 = C_2 \cup \{1, n-4\}$, $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n-3, n-2, n-1\}$ and $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n\}$. This transformation resolves the imbalance of $2n-6$ between $\mathtt{C}''_1$ and $\mathtt{C}''_2$ and will be called of type A.

Otherwise $1 \in C_1$ and $n-4 \in C_2$. If $2 \in C_2$ one defines $\mathtt{C}''_2 = C_2 \backslash \{2, n-4\}$, $\mathtt{C}''_1 = C_1 \cup \{2, n-4\}$, $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n-1\}$ and $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n, n-2, n-3\}$. This transformation balances classes $\mathtt{C}''_1$ and $\mathtt{C}''_2$ by $2n-4$ and will be called of type B.

Otherwise $2 \in C_1$, hence $C_1 = \{1, 2, \ldots\}$ and $C_2 = \{n-4, \ldots\}$. If $n-5 \in C_1$ then $\mathtt{C}''_1 = C_1 \backslash \{2, n-5\}$, $\mathtt{C}''_2 = C_2 \cup \{2, n-5\}$, $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n-3, n-2, n-1\}$ and $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n\}$.

Otherwise $n-5 \in C_2$, hence $C_1 = \{1, 2, \ldots\}$, $C_2 = \{n-4, n-5, \ldots\}$. Now if $3 \in C_2$ we move 3 and $n-5$ into C_1 and apply a type B transformation.

Otherwise $3 \in C_1$ and if $n-6 \in C_1$, we add $n-6$ and 3 to C_2 and apply a type A transformation; otherwise $C_1 = \{1, 2, 3, \ldots\}$ and $C_2 = \{n-4, n-5, n-6, \ldots\}$ and so on.

Note that a transformation of type A or B can be applied to every partition $\pi = C_1 \cup C_2$ of $\{1, \ldots, n-4\}$ since otherwise π must have classes $C_1 = \{1, 2, 3, \ldots\}$ and $C_2 = \{n-4, n-5, n-6, \ldots\}$ such that for every $k \in C_1$ verifying $1 \leq k \leq (n-4)/2$, the number $n-k-3$ belongs to C_2. But this contradicts the property that C_1 and C_2 have the same sum for every $n \geq 8$.

If $1 \in C_2$ this algorithm runs similarly and all partitions generated in this way are pairwise distinct.

(f) Suppose $3 \in C_1$. If $n-4 \in C_1$, we move 3 and $n-4$ into C_2 and annihilate the imbalance equal to $2n-2$ by defining $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n, n-1, n-3\}$ and $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n-2\}$ (a type C transformation).

Otherwise $C_1 = \{3, \ldots\}$, $C_2 = \{n-4, \ldots\}$. If $4 \in C_2$ we move 4 and $n-4$ into C_1 which produces an imbalance equal to $2n$; then define $\mathtt{C}'_1 = \mathtt{C}''_1 \cup \{n-3\}$ and $\mathtt{C}'_2 = \mathtt{C}''_2 \cup \{n, n-1, n-2\}$ (a type D transformation).

Otherwise $C_1 = \{3, 4, \ldots\}$ and $C_2 = \{n-4, \ldots\}$. If $n-5 \in C_1$ we move 4 and $n-5$ into C_2 and apply a type C transformation; otherwise $C_1 = \{3, 4, \ldots\}$ and $C_2 = \{n-4, n-5, \ldots\}$. In this way we can apply a transformation of type C or D to every partition π of $\{1, \ldots, n-4\}$ since otherwise $C_1 = \{3, 4, 5, \ldots\}$, $C_2 = \{n-4, n-5, n-6, \ldots\}$ such that for every $k \in C_1$, $3 \leq k \leq (n-2)/2$, we have $n-k-1 \in C_2$. This is a contradiction, since in this case C_1 and C_2 cannot have the same sum for every $n \geq 12$. As in the previous cases all partitions produced in this way are distinct. □

This theorem has the following consequence:

Corollary 2.4 *We have*

$$S(n) > 6^{n/4} \approx 1.56508^n \tag{5}$$

for every $n \equiv 0$ *or* $3 \ (mod\, 4)$ *and* $n \geq 16$.

Proof: If $n = 4k$ one gets $S(4k) \geq 6^{n/4-4} S(16) > 6^{n/4}$ since $S(16) = 1,314$. Similarly, $S(4k+3) \geq 6^{k-3} S(15) = 6^{(n-15)/4} S(15) > 6^{n/4}$ because $S(15) = 722$. □

Note that in [5] the maximum coefficient in the polynomial $G_n(x)$, which coincides with $S(n)$ for $n \equiv 0$ or 3 (mod 4), is bounded below by $2(n+1)$ for every $n \geq 10$.

Although the lower bound (5) is exponential, its order of magnitude is far from being exact, as can be seen below.

Lemma 2.5

$$\lim_{n\to\infty} S(4n)^{1/(4n)} = \lim_{n\to\infty} S(4n+3)^{1/(4n+3)} = 2. \tag{6}$$

Proof: Since the sequence of coefficients $(G(n,i))_{i=0,\ldots,T_n}$ in $G_n(x)$ is unimodal ([6, 7]) and symmetric, and the first and last coefficient are equal to 1, it follows that for every $n \geq 5$, $n \equiv 0$ or 3 (mod 4),

$$S(n) > \frac{2^n - 2}{T_n - 1} > \frac{2^n}{T_n} = \frac{2^{n+1}}{n^2 + n}.$$

Indeed, $\sum_{i=0}^{T_n} G(n,i) = G_n(1) = 2^n$ and $T_n < 2^{n-1}$ for every $n \geq 5$. On the other hand, $S(n) < 2^n - 2$, the number of ordered partitions having two classes of $\{1, \ldots, n\}$, and these two inequalities imply (6). □

A better upper bound for $S(n)$ is $\binom{n}{\lfloor n/2 \rfloor} \leq C_1 \frac{2^n}{\sqrt{n}}$ for some constant $C_1 > 0$. This follows from the following particular case of a result of Erdős (see [1] or [4]): Fix an interval of length 2 and consider the set of combinations $\sum_{i=1}^{n} \varepsilon_i i$, that lie within the interval, where $\varepsilon_i \in \{1, -1\}$ for every $1 \leq i \leq n$. The sets $\{i : \varepsilon_i = 1\}$ that correspond to these combinations form an antichain in the poset of subsets of $\{1, \ldots, n\}$ ordered by inclusion. By Sperner's theorem [8] the maximum number of elements in such an antichain is $\binom{n}{\lfloor n/2 \rfloor}$, which is an upper bound for the number of combinations $\sum_{i=1}^{n} \varepsilon_i i$ that sum to 0.

Conjecture 2.6 *For $n \equiv 0$ or 3 (mod 4) we have*

$$S(n) \sim \sqrt{6/\pi} \cdot \frac{2^n}{n\sqrt{n}},$$

where $f(n) \sim g(n)$ means that $\lim_{n\to\infty} f(n)/g(n) = 1$.

This behavior was verified by computer experiments up to $n = 100$.

3 Acknowledgements

The authors are grateful to J. Radcliffe from University of Nebraska (Lincoln) for useful discussions related to the upper bound for $S(n)$. Also, the authors are indebted to the referee of the paper for his/her very useful remarks, including the present form of Conjecture 2.6.

A Note on the Total Number of Double Eulerian Circuits in Multigraphs

Valery Liskovets[1]

Abstract

We formulate explicitly and discuss a simple new enumerative formula for double (directed) eulerian circuits in n-edged labeled multigraphs. The formula follows easily from a recent 2-parametric formula of B. Lass.

Multigraphs may have loops and are considered as symmetric multidigraphs. So, in an eulerian circuit, every edge is traversed exactly once in each direction (backtracks are allowed). With respect to undirected multigraphs such circuits are called here *double eulerian circuits*. A multigraph possesses a double eulerian circuit if and only if it is connected. We deal with *labeled* multigraphs, that is, multigraphs with numbered vertices. Moreover, any vertex may be distinguished as a *root*. If a multigraph is unrooted, then vertex 1 implicitly plays the role of the root.

[1]Supported in part by the INTAS (Grant INTAS-BELARUS 97-0093)

All double eulerian circuits are considered as starting and finishing at the root. Two circuits are *equivalent* if they differ only in the order in which parallel edges (including loops) or loops in both directions are traversed.

We define $(2n-1)!! = (2n-1)(2n-3)\cdots 5\cdot 3\cdot 1$. Our main result is the following.

Proposition 1 *Up to equivalence, the total number ε_n of double eulerian circuits in multigraphs with n edges is equal to* $(2n-1)!!\,\dfrac{3^{n+1}-1}{2(n+1)}$.

Indeed, by a theorem of Lass [1], the number of such circuits[2] in all *rooted* multigraphs with n edges and m vertices is $(2n-1)!!\,2^{m-1}\binom{n}{m-1}$. Since the vertices are labeled, the number of rootings is equal to m. Dividing the above formula by m and summing over all m we arrive at the desired expression. □

The corresponding numerical values of ε_n for $n = 0, 1, \ldots, 8$ are as follows: 1, 2, 13, 150, 2541, 57330, 1623105, 55405350, 2216439225. This is the sequence A069736 in Sloane [2]. The exponential generating function is $(\sqrt{1-2z} - \sqrt{1-6z})/2z$.

Example. $n = 2$. There are 4 unlabeled connected multigraphs with 2 edges. A graph on 3 vertices (path) with vertex 1 at an end (there are two such graphs) has only one double eulerian circuit. The same graph rooted at the middle vertex has two circuits. The graph consisting of two vertices and two parallel edges ("lune") also has two different circuits: $(1a2\bar{a}1b2\bar{b})$ and $(1a2\bar{b}1b2\bar{a})$ where a and b are the two (interchangeable) edges considered as directed from 1 to 2, and $\bar{a}$ and $\bar{b}$ are the same edges in the opposite direction. Likewise, the graph with two vertices and one loop has three double eulerian circuits if the vertex with the loop is labeled 1; otherwise the circuit is unique up to equivalence. Finally, the 1-vertex graph with two loops contains three different circuits: $(1a1\bar{a}1b1\bar{b})$, $(1a1b1\bar{a}1\bar{b})$ and $(1a1b1\bar{b}1\bar{a})$. So, there are $4+2+4+3 = 13$ double eulerian circuits in all.

Remarks.

1. Asymptotically ε_n grows as $Cn^{-3/2}\,6^n\cdot n!$, where $C = 3/(2\sqrt{\pi}\,)$.

2. By the same theorem of Lass, the total number ε'_n of double eulerian circuits in *rooted* labeled multigraphs with n edges is equal to $(2n-1)!!\,3^n$; numerically this is the sequence A011781 [2]: $1, 3, 27, 405, 8505, 229635, 7577955, 295540245, \cdots$

3. In contrast with topological maps, few closed formulae are known for the counting of abstract graphs (without isolated vertices) by the number of *edges*.

[2]Some of the above definition details are implicit in [1].

4. Are there any similar results for other classes of graphs and different types of equivalence of eulerian circuits?

5. At first glance, it seems as if we could use the same method to count double eulerian circuits *regardless of rooting* since every double eulerian circuit has one and the same number n of possible starting pairs (root, incident edge). Accordingly, the contribution to the total sum from any vertex taken as the root seems to be proportional to its valency. This idea, however, can be seen to fail because of multiple edges, loops and the definition of equivalence between circuits; cf. the example above. Nevertheless $n|\varepsilon_n$ for odd n (at the same time ε_n is odd for even n, so that n does not divide ε_n when n is even.)

Abstract

It is shown that a combinatorial method based on the principle of inclusion and exclusion (Sieve formula) yields generating functions for the enumeration of integer sequences chosen from 12 musical tones for the ragas (scales) of the Indian music system. Mathematical and computational schemes are presented for the enumeration and construction of integer [*] sequences pertinent to Indian music.

[*] Dedicated to Prof V. Krishnamurthy, my mentor and role model of Birla Intstitute of Tech & Sci, India

I. Introduction

Ragas or scales of musical notes with a characteristic pattern of ascent and descent constitute the basic melody of Indian music system [1]. There are two schools of Indian music system, the north Indian Hindustani music system and the south Indian or Carnatic music system. The sequence of notes in all music systems, also known as a chord, can be mapped into integral sequences, and the sequence on the ascent in the Indian music system is called an arohan (or arohanam), while the corresponding sequence on the descent is called the avarohan (or avarohanam). Each raga in the Indian music system is comprised of a unique sequence of notes in the ascent and descent that determines the characteristic of the raga and the musical forms and compositions that originate from the raga. In general, Carnatic music compositions and other forms of musical improvisations must contain the notes defined in the scale of the raga with the exception that for ornamentation and grace, other notes and microtones (notes with frequencies that lie between the frequencies of the 12-tone music system) may be added as in "gamakas"(distantly analogous to vibrato of western music) of the south Indian music system. The intimate connection between music and combinatorics has been a subject of several studies, for example, Babbitt's partition problems in the 12-tone western music compositions [2-4].

There are certain grammatical rules that govern the construction of ragas with the definition of Sa (C in western) and Pa (G in western) that form the basic reference point or "sruthi". The arohan or the avarohan of a raga should generally contain at least 4 notes. Although tertachord ragas are not very common, they do exist, as exemplified by the raga "Mahathi" [1]. The common forms of raga scales are pentatonic, known as the "audava" scales, that is, those containing five notes including the "Sa" (or C in western music), hexatonic, called the "shadava" and heptatonic or the complete (octave completed with static Ŝ included) scale called the "sampurna". A raga's ascent and descent can have a number of combinations of scales chosen from the eleven notes (12 with the upper-octave Ŝ) from the 12-tone system enumerated in Table 1 forming an integer sequence. If the scale is uniform in both ascent and descent without any repetition of a note then the raga is considered "non-kinky" or referred to as a "non-vakra"(vakra is a Sanskrit word meaning kinky) raga [1]. For example, a raga can be pentatonic in ascent and hexatonic in descent. It is then referred to as an

audava-shadava raga. We consider here enumeration of only non-vakra (non-kinky) ragas.

Scales of non-vakra ragas in south Indian music system are constructed by choosing the eleven notes (not counting the upper C or Sa, denoted as $\hat{S}$) in Table I so to form the various combinations of scales with uniformly rising frequency in the ascent and decreasing frequency in the descent. If the 11 notes are mapped into integers then in combinatorial terms this corresponds to the enumeration of integer sequences under constraints and equivalences as stipulated by the theory of south Indian music. The objective of this article is to construct the mathematical foundation for such an exhaustive and yet non-repetitive enumeration and generating functions for the ragas of different kinds of scales. This rigorous and exhaustive enumeration scheme provides a basis for the formulation of new ragas that are not known up to now in the south Indian music system or Carnatic music [1]. A computer code is also developed for the construction of such ragas.

2. Combinatorics of integer Sequences of ragas

In mathematical notation the notes in Table I are denoted as S, R_1, R_2, R_3,…..N_3, the last being $\hat{S}$, and has an octavial relation to S. These notes have characteristic rational number relations to the base frequency of S. The arohan or avarohan should contain a combination of notes in Table I according to whether the scale is “pentatonic”, “hexatonic” and so on. There are a few restrictions and equivalences. The notes should appear as a sequence of increasing frequencies (in the order shown in table I) with the restriction that only one kind of R or G or M or D or N may appear in a scale, and certain notes are considered equivalent. The notes G_1 and R_2 are equivalent. Likewise the notes G_2 and R_3 are equivalent. The notes N_1 and D_2 are equivalent, while the notes N_2 and D_3 are equivalent. Thus the enumeration of all possible “non-kinky” ragas of Carnatic music system becomes enumerating integral sequences of a prescribed length under equivalence constraints. The Carnatic music system thus uses two different names for the same note. The main advantage is that certain combination becomes allowed when different names are used for the same note, for example, the combination R_1-G_1 or suddha Ri and suddha Ga becomes allowed under this convention [1] in the Carnatic music, but the same combination which becomes komal Ri-Sudh Ri in the north Indian Hindustani music system is forbidden. The use of multiple names for the same note is not unique to Carnatic music, as it is also the case with western

music, as can be seen from Table I. For example, E double flat is the same note as D natural, E flat is same as D sharp and so on (Table I).

The enumeration of patterns under equivalences or "equivalence classes" can be formulated by the well-known Polya's theorem and there are many chemical and spectroscopic applications of Polya's theorem [5-7]. However, for the present purpose, since the enumeration often involves integer sequences with certain combinations forbidden due to equivalence restrictions, we find the principle of inclusion and exclusion or the sieve formula [8-10] to be a more convenient choice for the enumeration. This corresponds to enumerating integer sequences with increasing order on the ascent (or decreasing order on the descent) such that certain sequences are forbidden. There are many such applications of enumerative combinatorics [8-12] such as derangements or the problem of Ménage or the Euler function, which generates the number of primes to any integer n and less than n, and also the Reimann-Zeta function [12] related to the prime number distributions rediscovered by Srinivasa Ramanujan [13]. It should also be noted that there is considerable interest in combinatorial problems in western music theory [2-4] known as "Babbitt's partition problems" in 12-tone musical compositions. One of the Babbitt's partition problem asks for an algorithm for determining all mxm matrices with entries drawn from the set {1, 2, ... ,n} for which all rows and columns have the sum n [4].

Let $P_1, P_2, P_3,\ldots P_n$ be a set of n constraints stipulated by the south Indian music theory. Then the generating function F for the enumeration such that none of the constraints $P_1, P_2, P_3, \ldots P_n$ is satisfied is given by the Sieve formula

$$F = f(0) - f(1) + f(2) - f(3) + \ldots\ldots + (-1)^i f(i) + \ldots (-1)^n f(n) ,$$

where f (i) denotes the generating function for the enumeration that satisfies exactly i of the properties $P_1, P_2, \ldots\ldots P_n$.

The constraints $P_1, P_2 \ldots P_n$ can be constructed for the enumeration of ragas as P_1 being that the sequence of notes R_2 and G_1 occurs (forbidden due to equivalence), P_2: notes R_3 and G_2 are in a sequence (forbidden sequence), P_3: notes R_3 and G_1(forbidden), P_4: D_2 and N_1, P_5: D_3 and N_2, P_6: D_3 and N_1. P_3 and P_6 are forbidden by symmetry in that the R_2-G_2 combination is equivalent to the R_3-G_1 combination. The D_2-N_2 combination is equivalent to D_3-N_1. Thus we are enumerating "patterns" of integer sequences or "equivalence classes".

To illustrate, the number of symmetrical "heptatonic-heptatonic" also known as "sampurna-sampurna" ragas in the Carnatic music system (or the "melakarta (creator) ragas") [1], the numbers *f (0), f (1), f (2)…. f (6)* are obtained as

$$f(0) = \binom{3}{1}\binom{3}{1}\binom{2}{1}\binom{3}{1}\binom{3}{1} = 162$$

$$f(1) = \binom{2}{1}\binom{3}{1}\binom{3}{1} \times 6 = 108$$

$$f(2) = 9 \times \binom{2}{1} = 18$$

$$f(3) = f(4) = f(5) = f(6) = 0$$

Thus F is given by

$$F = f(0) - f(1) + f(2) - f(3) + f(4) - f(5) + f(6)$$

$$= 162 - 108 + 18 = 72$$

The above enumeration is a straight forward application since all notes occur in a heptatonic sequence, that is, S, R, G, M, P, D, and N, occur and the constraint that only one note form a given type such as R or G may be chosen makes it easier to enumerate these sequences.

3. Generating Functions for ragas

The enumerations of different types of scales such as audava (ascent)-audava (descent), audava (ascent)-shadava (descent) etc., can be accomplished utilizing powerful enumerative combinatorial functions. We shall construct a "pattern inventory" in Polya's term [5-7] of all such "non-vakra" or non-kinky ragas of Carnatic music system. We construct a generating function for the ascent and multiply the corresponding generating function for the descent to get the complete pattern inventory of ragas. The ascent GF is constructed by enumerative combinatorics. The maximal chord length allowed is 7 in a sampurna non-vakra (non-kinky heptatonic) type, and that has already been enumerated. The hexatonic (shadava) arohans are enumerated as follows. First the patterns are enumerated for the hexatonic scales as shown in Table II and then the numbers for each pattern. A hexatonic pattern such as S G M P D N Ŝ can be mathematically characterized as $\overline{R}$, since it is missing R (known as

rishaba vajra[1]) from a complete heptatonic scale. Thus there are six patterns characterized by $\overline{R}$, $\overline{G}$, $\overline{M}$, $\overline{P}$, $\overline{D}$, and $\overline{N}$. Note that S cannot be missing from a raga as it forms the base (C). The equivalence classes of ragas in each such pattern are enumerated using the Sieve formula [8-10] and thus we have the hexatonic ascent (arohan) generating function as

$$H^a = (12\overline{R} + 36\overline{G} + 36\overline{M} + 72\overline{P} + 12\overline{D} + 36\overline{N}),$$

where, for example, there are 12 hexatonic scales missing R, 36 missing G and so on. In this enumeration scheme the equivalence of notes has been considered, and thus all combinations are allowed in $\overline{G}$, while only non-equivalent ones are considered in $\overline{R}$. The total number of hexatonic arohans is obtained by substituting

$$\overline{R} = 1, \overline{G} = 1, ... \overline{N} = 1$$

in the above expression which yields 204 hexatonic arohans. This also corresponds to the number of symmetric hexatonic-hexatonic or the "shadava-shadava" ragas.

The pentatonic scales are those that have two missing notes relative to the heptatonic scales and are thus denoted in mathematical terms by binomials such as $\overline{R}\,\overline{G}$, $\overline{R}\,\overline{M}$, etc., as enumerated in Table III. The patterns are shown in Table III, and the generating function for the pentatonic ascent is given by

$$P^a = (12\overline{R}\,\overline{G} + 6\overline{R}\,\overline{M} + 12\overline{R}\,\overline{P} + 2\overline{R}\,\overline{D} + 6\overline{R}\,\overline{N} + 18\overline{G}\,\overline{M} + 36\overline{G}\,\overline{P} + 6\overline{G}\,\overline{D} + 18\overline{G}\,\overline{N} + 36\overline{M}\,\overline{P} + 6\overline{M}\,\overline{D} + 18\overline{M}\,\overline{N} + 12\overline{P}\,\overline{D} + 36\overline{P}\,\overline{N} + 12\overline{D}\,\overline{N})$$

In the above enumeration scheme the equivalence of notes has been considered and thus the combinations with $\overline{R}\,\overline{M}$ have fewer numbers than $\overline{G}\,\overline{M}$, since they have been already enumerated in the binomial $\overline{G}\,\overline{M}$ they are not duplicated in $\overline{R}\,\overline{M}$, due to symmetry equivalence. Replacing all binomial terms by 1 or equivalently summing the coefficients gives the total number of symmetric pentatonic ragas or pentatonic ascents as 236.

Although ragas with tetratonic (tertachord) scales are rare, they do occur as illustrated before, and thus they are enumerated here for completeness. Such enumerations can also be useful in computer synthesis of musical tertachord compositions, wherein a sequence of four notes is required. The tetratonic GF is given by

$$T^a = (6\overline{RGM} + 12\overline{RGP} + 2\overline{RGD} + 6\overline{RGN} + 6\overline{RMP} + \overline{RMD}$$
$$+ 3\overline{RMN} + 2\overline{RPD} + 6\overline{RPN} + 2\overline{RDN} + 18\overline{GMP} +$$
$$+ 3\overline{GMD} + 9\overline{GMN} + 6\overline{GPD} + 18\overline{GPN} + 6\overline{GDN} + 6\overline{MPD}$$
$$+ 18\overline{MPN} + 6\overline{MDN} + 6\overline{PDN})$$

Again in the above enumeration all possibilities are allowed for R and D, but the ones with G and N, only non-equivalent types are enumerated by way of inclusion-exclusion to eliminate equivalent combinations. Thus the total number of tetratonic scales, also referred to in music theory as tetrachords (sequence of 4 notes), is obtained by substituting all trinomials in T^a by 1 or summing the coefficients in T^a. Thus the number of tertachords or tetratonic ascents is 142.

The trichords (triplets) or sequences of three notes, one of which is S, are enumerated by the expression for Tr^a.

$$Tr^a = (6RG + 6RM + 3RP + 9RD + 3RN + 2GM + GP + 3GD + GN$$
$$+ 2MP + 6MD + 2MN + 3PD + PN + 6DN),$$

where in the above expression instead of complementary notation, the notes themselves are used for the binomials, for example, RG to denote the sequence SRG in the trichord. Thus the total number of trichords is obtained by adding the coefficients in TR^a, which equals 54. The number of dichords or a sequence of 2 notes, one of which has to be S, is simply 11 since that is the number of distinct notes in Table I (note $\hat{S}$ is related to S by an octave).

All of the above expressions can be combined into a pattern inventory of arohans of ragas that we refer to as a raga ascent inventory, RI^a, given as a polynomial in x, where x^n denotes the term for n-tonic ascent.

$$RI^a = 1 + x + 11x^2 + 54x^3 + 142x^4 + 236x^5 + 204x^6 + 72x^7 \ ,$$

where the first term is a trivial null set, the second term corresponds to a single note or just S, the x^2 term representing the number of dichords, x^3: the number of trichords, x^4: number of tetrachords etc. For a raga to be stable its scale must have at least a tetrachord, and thus terms with powers more than or equal to 4 are relevant for the scales of ragas.

The Raga inventory for the descent (avarohan) is likewise enumerated by the generating function RI^d given by

$$RI^d = 1 + y + 11y^2 + 54y^3 + 142y^4 + 236y^5 + 204y^6 + 72y^7 \ ,$$

where the symbol y is used to distinguish the descent from the ascent to allow for the possibility of unsymmetrical and bhashanka ragas [1]. The total generating function for all of the ragas is given by the product of the ascent and descent inventories or

$$RI = RI^a \times RI^d = (1 + x + 11x^2 + 54x^3 + 142x^4 + 236x^5 + 204x^6 + 72x^7) \times$$
$$(1 + y + 11y^2 + 54y^3 + 142y^4 + 236y^5 + 204y^6 + 72y^7),$$

The coefficient of $x^m y^n$ in the above generating function enumerates the number of ragas with m-tonic (m-chord) notes in ascent omitting higher octave Ŝ and n-tonic notes (n-chord) in the descent. For example, the number of shadava-sampurna ragas is given by the coefficient of $x^6 y^7$ in the above expression, which is 14688. The number of symmetrical tetrachords is the coefficient of x^4 which is 142 and the total number of all tetratonic ragas is the coefficient of $x^4 y^4$, which is 20164. All of the symmetrical ragas are enumerated by the terms x^5, x^6 and x^7 for the pentatonic (audava), hexatonic (shadava) and heptatonic (sampurna) scales, respectively. The number of ragas with at least pentatonic scales in the ascent or descent is enumerated in Table IV. It should be mentioned that Pattamal [14] has proposed a scientific naming scheme for some of the ragas, and the numbers obtained before are not rigorously correct [15] as these empirical methods either missed some of the combinations or those methods do not fully consider equivalence

restrictions. As mentioned in ref [15] also, earlier counting schemes also suffered from duplication. In the present scheme, we have carefully provided a mathematical framework within combinatorial principles that stipulates equivalence, symmetry and other restrictions and it is yet exhaustive as the polynomial inventory rigorously considers all of the combinations.

More detailed combinatorial generating functions can be constructed by considering the generating functions, H^a, P^a, T^a and Tr^a. For example detailed enumeration for the hexatonic (shadava)-pentatonic (audava) ragas is given by

$$H^a P^d = H^a P^d = [12\overline{R} + 36\overline{G} + 36\overline{M} + 72\overline{P} + 12\overline{D} + 36\overline{N}]$$
$$\times [12\overline{R}'\overline{G}' + 6\overline{R}'\overline{M}' + 12\overline{R}'\overline{P}' + 2\overline{R}'\overline{D}' + 6\overline{R}'\overline{N}' + 18\overline{G}'\overline{M}' + 36\overline{G}'\overline{P}' +$$
$$6\overline{G}'\overline{D}' + 18\overline{G}'\overline{N}' + 36\overline{M}'\overline{P}' + 6\overline{M}'\overline{D}' + 18\overline{M}'\overline{N}' + 12\overline{P}'\overline{D}'$$
$$+ 36\overline{P}'\overline{N}' + 12\overline{D}'\overline{N}']$$

The above expression enumerates all combinations of hexatonic-pentatonic ragas. For example, the number of ragas missing R in the ascent and missing G and P in the descent is given by the coefficient of $\overline{R}\,\overline{G}'\overline{P}'$, which is 432. Consequently, combining different ascent generating functions with different descent generating functions, all ragas, both symmetrical and unsymmetrical are enumerated. The generating function contains all symmetrical and unsymmetrical tetrachords, trichords, bichords, etc.

Tables II and III contain the detailed enumerations for the most common ragas of different types. Since the number of heptatchords is 72, the number of heptatonics with any combination is obtained by multiplying the corresponding GF by 72.

We have also developed a computer code to construct all ragas (scales) of a given type. Table V illustrates the computer construction of 1296 hexatonic (shadava)-hexatonic (shadava) symmetrical and unsymmetrical ragas. This table was constructed from a computer generation scheme. We show only the first 212 and the last 220 ragas. Full pdf file of all 1296 ragas or any desired combination could be obtained from the author.

[a]Note that full enumeration is included for ragas that have R and D, and thus equivalences of $G_1=R_2$, $G_2=R_3$, $N_1=D_2$, $N_2=D_3$ are invoked so that combinations that have G or N will include only unique ragas, that is, those that contain only G_3 and N_3(kakali Nishadha). For example, in ragas with S R G M P N Ŝ, for $N=N_2$ (kaisiki Nishada) are already enumerated in S R G M P D Ŝ with $D=D_3$.

Table III 55696 Pentatonic ragas (scales) of Carnatic Music system. Only Arohans(Ascents) are shown. The complete set is obtained by the combinatorial generating function (equation) in the text.

Abstract. We give a more practical variant of Shanks' 1954 algorithm for computing the continued fraction of $\log_b a$, for integers $a > b > 1$, using the floor and ceiling functions and an integer parameter $c > 1$. The variant, when repeated for a few values of $c = 10^r$, enables one to guess if $\log_b a$ is rational and to find approximately r partial quotients.

1. Shanks' algorithm

In his article [1], Shanks gave an algorithm for computing the partial quotients of $\log_b a$, where $a > b$ are positive integers greater than 1. Construct two sequences $a_0 = a, a_1 = b, a_2, \ldots$ and $n_0, n_1, n_2, \ldots$, where the a_i are positive rationals and the n_i are positive integers, by the following rule: If $i \geq 1$ and $a_{i-1} > a_i > 1$, then

$$a_i^{n_{i-1}} \leq a_{i-1} < a_i^{n_{i-1}+1} \tag{1.1}$$

$$a_{i+1} = a_{i-1}/a_i^{n_{i-1}}. \tag{1.2}$$

Clearly (1.1) and (1.2) imply $a_i > a_{i+1} \geq 1$. Also (1.1) implies $a_i \leq a_{i-1}^{1/n_{i-1}}$ for $i \geq 1$ and hence by induction on $i \geq 0$,

$$a_{i+1} \leq a_0^{1/n_0 \cdots n_i}. \tag{1.3}$$

Also by induction on $j \geq 0$, we get

$$a_{2j} = a_0^r/a_1^s, \quad a_{2j+1} = a_1^u/a_0^v, \tag{1.4}$$

where r and u are positive integers and s and v are non–negative integers.

Two possibilities arise:

(i) $a_{r+1} = 1$ for some $r \geq 1$. Then equations (1.4) imply a relation $a_0^q = a_1^p$ for positive integers p and q and so $\log_{a_1} a_0 = p/q$.

(ii) $a_{i+1} > 1$ for all i. In this case the decreasing sequence $\{a_i\}$ tends to $a \geq 1$. Also (1.3) implies $a = 1$, unless perhaps $n_i = 1$ for all sufficiently large i; but then (1.2) becomes $a_{i+1} = a_{i-1}/a_i$ and hence $a = a/a = 1$.

If $a_{i-1} > a_i > 1$, then from (1.1) we have

$$n_{i-1} = \left\lfloor \frac{\log a_{i-1}}{\log a_i} \right\rfloor. \tag{1.5}$$

Let $x_i = \log_{a_{i+1}} a_i$ if $a_{i+1} > 1$. Then we have

Lemma 1. *If $a_{i+2} > 1$, then*

$$x_i = n_i + 1/x_{i+1}. \tag{1.6}$$

Proof. From (1.2), we have

$$\log a_{i+2} = \log a_i - n_i \log a_{i+1} \tag{1.7}$$

$$1 = \frac{\log a_i}{\log a_{i+1}} \cdot \frac{\log a_{i+1}}{\log a_{i+2}} - n_i \cdot \frac{\log a_{i+1}}{\log a_{i+2}} \tag{1.8}$$

$$= x_i x_{i+1} - n_i x_{i+1}, \tag{1.9}$$

from which (1.6) follows. □

From Lemma 1.1 and (1.5), we deduce

Lemma 2. (a) *If $\log_{a_1} a_0$ is irrational, then*

$$x_i = n_i + 1/x_{i+1} \text{ for all } i \geq 0.$$

(b) *If $\log_{a_1} a_0$ is rational, with $a_{r+1} = 1$, then*

$$x_i = \begin{cases} n_i + 1/x_{i+1}, & \text{if } 0 \leq i < r-1; \\ n_{r-1}, & \text{if } i = r-1. \end{cases}$$

In view of the equation $\log_{a_1} a_0 = x_0$, Lemma 2 leads immediately to

Corollary 1.

$$\log_{a_1} a_0 = \begin{cases} [n_0, n_1, \ldots], & \text{if } \log_{a_1} a_0 \text{ is irrational;} \\ [n_0, n_1, \ldots, n_{r-1}], & \text{if } \log_{a_1} a_0 \text{ is rational and } a_{r+1} = 1. \end{cases} \tag{1.10}$$

Remark. It is an easy exercise to show that for $j \geq 0$,

$$a_{2j} = a_0^{q_{2j-2}}/a_1^{p_{2j-2}}, \quad a_{2j+1} = a_1^{p_{2j-1}} a_0^{q_{2j-1}} \tag{1.11}$$

where p_k/q_k is the k–th convergent to $\log_{a_1} a_0$.

Example 1. $\log_2 10$: Here $a_0 = 10,\ a_1 = 2$. Then $2^3 < 10 < 2^4$, so $n_0 = 3$ and $a_2 = 10/2^3 = 1.25$.

Further, $1.25^3 < 2 < 1.25^4$, so $n_1 = 3$ and $a_3 = 2/1.25^3 = 1.024$.

Also, $1.024^9 < 1.25 < 1.024^{10}$, so $n_2 = 9$ and

$$\begin{aligned} a_4 &= 1.25/1.024^9 \\ &= 125000000000000000000000000/123794003928538027489912422 4 \\ &= 1.0097419586\cdots \end{aligned}$$

Continuing in this fashion, we obtain Table 1 and $\log_2 10 = [3, 3, 9, 2, 2, 4, 6, 2, 1, 1, \ldots]$.

i	n_i	a_i	p_i/q_i
0	3	10	3/1

TABLE 1.

2. Some Pseudocode

In Table 2 we present pseudocode for the Shanks algorithm.

It soon becomes impractical to perform the calculations in multiprecision arithmetic, as the numerators and denominators a_i grow rapidly. If we truncate the decimal expansions of the `a[i]` to r places and represent a positive rational a as $g(a)/10^r$, where $g(a) = \lfloor 10^r a \rfloor$, the ratio `aa/bb` will be calculated as $\lfloor 10^r g(aa)/g(bb) \rfloor$. Working explicitly in integers, using the $g(a)$, then results in algorithm 1, also depicted in Table 2, with $c = 10^r$, where `int(x,y)` equals $\lfloor x/y \rfloor$, when x and y are integers.

As shown in the next section, the `A[i]` decrease strictly until they reach `c`. Also `m[0]=n[0]` and we can expect a number of the initial `m[i]` will be partial quotients. Naturally, the larger we take c, the more partial quotients will be produced.

Shanks' algorithm	algorithm 1
`input: integers a>b>1`	`input: integers a>b>1, c> 1`
`output: n[0],n[1],...`	`output: m[0],m[1],...`

`}`	`}`

TABLE 2.

3. Formal description of algorithm 1

We show in Theorem 2.1 below, that algorithm 1 will give the correct partial quotients when $\log_{a_1} a_0$ is rational and otherwise gives a parameterised sequence of integers which tend to the correct partial quotients when $\log_{a_1} a_0$ is irrational.

Algorithm 1 is now explicitly described. We define two integer sequences $\{A_{i,c}\}$, $i = 0, \ldots, l(c)$ and $\{m_{j,c}\}$, $j = 0, \ldots, l(c)-2$, as follows.

Let $A_{0,c} = c \cdot a_0, A_{1,c} = c \cdot a_1$. Then if $i \geq 1$ and $A_{i-1,c} > A_{i,c} > c$, we define $m_{i-1,c}$ and $A_{i+1,c}$ by means of an intermediate sequence $\{B_{i,r,c}\}$, defined for $r \geq 0$, by $B_{i,0,c} = A_{i-1,c}$ and

$$B_{i,r+1,c} = \left\lfloor \frac{cB_{i,r,c}}{A_{i,c}} \right\rfloor, r \geq 0. \tag{3.1}$$

Then $c \leq B_{i,r+1,c} < B_{i,r,c}$, if $B_{i,r,c} \geq A_{i,c} > c$ and hence there is a unique integer $m = m_{i-1,c} \geq 1$ such that

$$B_{i,m,c} < A_{i,c} \leq B_{i,m-1,c}.$$

Then we define $A_{i+1,c} = B_{i,m,c}$. Hence $A_{i+1,c} \geq c$ and the sequence $\{A_{i,c}\}$ decreases strictly until $A_{l(c),c} = c$.

There are two possible outcomes, depending on whether or not $\log_b(a)$ is rational:

Theorem 2. (1) *If* $\log_{a_1} a_0$ *is a rational number* p/q *with* $p > q \geq 1$ *and* $\gcd(p,q) = 1$, *then*

(a) $a_0 = d^p$, $a_1 = d^q$ *for some positive integer* d;

(b) *if* $p/q = [n_0, \ldots, n_{r-1}]$, *where* $n_{r-1} > 1$ *if* $r > 1$, *then*
  (i) $A_{r+1,c} = c, a_{r+1} = 1$;
  (ii) $A_{i,c} = c \cdot a_i$ *for* $0 \le i \le r+1$;
  (iii) $m_{i,c} = n_i$ *for* $0 \le i \le r-1$.

(2) *If* $\log_{a_1} a_0$ *is irrational, then*
  (a) $m_{0,c} = n_0$;
  (b) $l(c) \to \infty$ *and for fixed* i, $A_{i,c}/c \to a_i$ *as* $c \to \infty$ *and* $m_{i,c} = n_i$ *for all large* c.

Proof. 1(a) follows from the equation $a_1^p = a_0^q$.

1(b) is also straightforward on noticing that a_i is a power of d and that we are implicitly performing Euclid's algorithm on the pair (p, q).

For 2(a), we have

$$a_1^{n_0} < a_0 < a_1^{n_0+1} \tag{3.2}$$

and $A_{0,c} = c \cdot a_0$, $A_{1,c} = c \cdot a_1$. Also by induction on $0 \le r \le n_0$,

$$B_{1,r,c} \ge ca_1^{n_0-r}, \tag{3.3}$$

$$B_{1,r,c} \le \frac{ca_0}{a_1^r}. \tag{3.4}$$

Inequality (3.3) with $r \le n_0 - 1$ gives $B_{1,r,c} \ge A_{1,c}$, while inequality (3.4) with $r = n_0$ gives

$$B_{1,n_0,c} \le \frac{ca_0}{a_1^{n_0}} < ca_1 = A_{1,c},$$

by inequality (3.2). Hence $m_{0,c} = n_0$.

For 2(b), we use induction on $i \ge 1$ and assume $l(c) \ge i$ holds for all large c and that $A_{i-1,c}/c \to a_{i-1}$ and $A_{i,c}/c \to a_i$ as $c \to \infty$. This is clearly true when $i = 1$.

By properties of the integer part symbol, equation (3.1) gives

$$\frac{c^r A_{i-1,c}}{A_{i,c}^r} - \frac{(1 - \frac{c^r}{A_{i,c}^r})}{1 - \frac{c}{A_{i,c}}} < B_{i,r,c} \le \frac{c^r A_{i-1,c}}{A_{i,c}^r}. \tag{3.5}$$

for $r \ge 0$.

Hence for $r < n_{i-1}$, inequalities (3.5) give

$$B_{i,r,c}/c \to a_{i-1}/a_i^r \ge a_{i-1}/a_i^{n_{i-1}-1} > a_i.$$

Then, because $A_{i,c}/c \to a_i$, it follows that $B_{i,r,c} > A_{i,c}$ for all large c.

Also $B_{i,n_{i-1},c}/c \to a_{i-1}/a_i^{n_{i-1}} < a_i$, so $B_{i,n_{i-1},c} < A_{i,c}$ for all large c. Hence $m_{i-1,c} = n_{i-1}$ for all large c. Also $A_{i+1,c} = B_{i,n_{i-1},c} > c$, so $l(c) > i + 1$ for all large c. Moreover $A_{i+1,c}/c \to a_{i-1}/a_i^{n_{i-1}} = a_{i+1}$ and the induction goes through. □

Example 3. Table 3 lists the sequences $m_{0,c}, \ldots, m_{l(c)-2,c}$ for $c = 2^u, u = 1, \ldots, 30$, when $a_0 = 3, a_1 = 2$.

TABLE 3.

In fact $\log_2 3 = [1, 1, 1, 2, 2, 3, 1, 5, 2, 23, 2, \ldots]$.

4. A heuristic algorithm

We can replace the $\lfloor x \rfloor$ function in equation (3.1) by $\lceil x \rceil$, the least integer exceeding x.

This produces an algorithm with similar properties to algorithm 1, with integer sequences $\{A'_{i,c}\}$, $i = 0, \ldots, l'(c)$ and $\{m'_{j,c}\}$, $j = 0, \ldots, l'(c)-2$. Here $A_{0,c} = A'_{0,c} = a_0 \cdot c$, $A_{1,c} = A'_{1,c} = a_1 \cdot c$ and $m_{0,c} = m'_{0,c} = n_0$. Then if $i \geq 1$ and $A'_{i-1,c} > A'_{i,c} > c$, we define $m'_{i-1,c}$ and $A'_{i+1,c}$ by means of an intermediate sequence $\{B'_{i,r,c}\}$, defined for $r \geq 0$, by $B'_{i,0,c} = A'_{i-1,c}$ and

$$B'_{i,r+1,c} = \left\lceil \frac{cB'_{i,r,c}}{A'_{i,c}} \right\rceil, r \geq 0. \tag{4.1}$$

Then $c \leq B'_{i,r+1,c} < B'_{i,r,c}$, if $B'_{i,r,c} \geq A'_{i,c} > c$.

For

$$B'_{i,r+1,c} \leq \frac{cB'_{i,r,c}}{A'_{i,c}} + 1$$

and

$$\frac{cB'_{i,r,c}}{A'_{i,c}} + 1 \leq B'_{i,r,c} \quad \Leftrightarrow \quad cB'_{i,r,c} + A'_{i,c} \leq A'_{i,c}B'_{i,r,c}$$

$$\Leftrightarrow \quad \frac{A'_{i,c}}{A'_{i,c} - c} \leq B'_{i,r,c}.$$

The last inequality is certainly true if $B'_{i,r,c} \geq A'_{i,c} > c$.

Hence there is a unique integer $m' = m'_{i-1,c} \geq 1$ such that

$$B'_{i,m',c} < A'_{i,c} \leq B'_{i,m'-1,c}.$$

Then we define $A'_{i+1,c} = B'_{i,m',c}$. Hence $A'_{i+1,c} \geq c$ and the sequence $\{A'_{i,c}\}$ decreases strictly until $A'_{l'(c),c} = c$.

If we perform the two computations simultaneously, the common initial elements of the sequences $\{m_{j,c}\}$ and $\{m'_{k,c}\}$ are likely to be partial quotients of $\log_b(a)$. With $c = 10^r$ we expect roughly r partial quotients to be produced.

If $l(c) = l'(c)$ and $A_{j,c} = A'_{j,c}$ and $m_{j,c} = m'_{j,c}$ for $j = 0, \ldots, l(c) - 2$, then $\log_b a$ is likely to be rational.

In practice, to get a feeling of certainty regarding the output when $c = 10^r$, we also run the algorithm for $c = 10^t, r - 5 \leq t \leq r + 5$.

Example 4. Table 4 lists the common values of $m_{i,c}$ and $m'_{i,c}$, when $a = 3, b = 2$ and $c = 2^r, 1 \leq r \leq 31$. It seems likely that only partial quotients are produced for all $r \geq 1$.

Tau Numbers: A Partial Proof of a Conjecture and Other Results

Joshua Zelinsky

USA

Email: Lord_Bern@hotmail.com

Abstract. A positive n is called a *tau number* if $\tau(n) \mid n$, where τ is the number-of-divisors function. Colton conjectured that the number of tau numbers $\leq n$ is at least $\frac{1}{2}\pi(n)$. In this paper I show that Colton's conjecture is true for all sufficiently large n. I also prove various other results about tau numbers and their generalizations .

1 Introduction

Kennedy and Cooper [3] defined a positive integer to be a *tau number* if $\tau(n) \mid n$, where τ is the number-of-divisors function. The first few tau numbers are

$$1, 2, 8, 9, 12, 18, 24, 36, 40, 56, 60, 72, 80, \ldots;$$

it is Sloane's sequence A033950. Among other things, Kennedy and Cooper showed the tau numbers have density zero.

The concept of tau number was rediscovered by Colton, who called these numbers *refactorable* [1]. This paper is primarily concerned with two conjectures made by Colton. Colton conjectured that the number of tau numbers less than or equal to a given n was at least half the number of primes less than or equal to n. In this paper I show that Colton's conjecture is true for all sufficiently large n by proving a generalized version of the conjecture. I calculate an upper bound for counterexamples of $7.42 \cdot 10^{13}$.

Colton also conjectured that there are no three consecutive tau numbers and I show this to be the case. Other results are also given, including the properties of the tau numbers as compared to the primes. Various generalizations of the tau numbers are also discussed.

2 Basic results

Definitions. Let $\pi(n)$ be the number of primes less than or equal to n. Let $T(n)$ be the number of tau numbers less than or equal to n.

Using this notation, Colton's conjecture becomes: $T(n) \geq \pi(n)/2$ for all n.

Before we prove a slightly weaker form of this conjecture, we mention some following minor properties of the tau numbers.

Throughout this paper, the following basic result [2, Theorem 273] is used extensively:

Proposition 1. *If* $n = p_1^{a_1} p_2^{a_2} \cdots p_k^{a_k}$ *then* $\tau(n) = (a_1+1)(a_2+1)(a_3+1)\cdots(a_k+1)$.

The next five theorems are all due to Colton.

Theorem 2. *Any odd tau number is a perfect square.*

Proof. Assume that n is an odd tau number. Let $n = p_1^{a_1} p_2^{a_2} \cdots p_k^{a_k}$. By Proposition 1 and the definition of tau number $(a_1+1)(a_2+1)(a_3+1)\ldots(a_k+1) \mid n$. Therefore for any $0 < i < k+1$, $a_i + 1$ is odd, and hence a_i is even. Since every prime in the factorization of n is raised to an even power, n is a perfect square. □

Theorem 3. *An odd integer* n *is a tau number iff* $2n$ *is a tau number.*

Proof. If $n = p_1^{a_1} p_2^{a_2} \cdots p_k^{a_k}$, then $\tau(2n) = 2(a_1+1)(a_2+1)(a_3+1)\cdots(a_k+1) = 2\tau(n)$. Since $\tau(n) \mid n$ iff $2\tau(n) \mid 2n$, the result follows. □

Theorem 4. *If* $\gcd(m,n) = 1$ *and* m, n *are both tau numbers, then* mn *is a tau number.*

Proof. This result follows immediately from $\tau(mn) = \tau(m)\tau(n)$ when $\gcd(m,n) = 1$. □

Theorem 5. *There are infinitely many tau numbers.*

There are many possible ways to prove this result. However, using an elegant mapping Colton proved the following more general theorem from which the above follows.

Theorem 6. *For any given finite nonempty set of primes, there are infinitely many tau numbers with exactly those primes as their distinct prime divisors.*

Proof. This result follows from considering the mapping:

$$f(n) = f(p_1^{a_1} p_2^{a_2} \cdots p_k^{a_k}) = p_1^{p_1^{a_1}-1} p_2^{p_2^{a_2}-1} \cdots p_k^{p_k^{a_k}-1}.$$

It is easy to see that the mapping produces only tau numbers. □

Theorem 7. *Every tau number is congruent to 0,1,2 or 4 mod 8.*

Proof. This follows immediately from Theorems 2 and 3. □

3 New Results

We now turn to the new results of this paper.

First, we have a minor, elementary result which is similar to Colton's above results.

Theorem 8. *Let n be a tau number and let p be the smallest prime factor of n. If q is prime and $q \mid n$ then $q^{p-1} \mid n$.*

Proof. Let n be a tau number and let p be the smallest prime factor of n. Let q be a prime which divides n and let q^k be the largest power of q which divides n. Since n is a tau number, $k+1 \mid n$. But p is the smallest non-trivial divisor of n so $k+1 \geq p$. Hence $k \geq p-1$ and thus $q^{p-1} \mid n$. □

To prove that Colton's first conjecture is true for all sufficiently large n we construct a subset of the tau numbers which is much denser than the primes.

Lemma 9. *For any distinct primes $p, q > 3$, the number $36pq$ is a tau number.*

Proof. By the multiplicative property of the tau function, $\tau(36pq) = \tau(4)\tau(9)\tau(p)\tau(q) = 3 \cdot 3 \cdot 2 \cdot 2 = 36$. □

Lemma 10. *Let k be an integer ≥ 1. Then the number of integers $\leq n$ of the form kp, where p is prime, is asymptotic to $n/(k \log n)$. Similary, for any fixed integer $a \geq 1$ the numbers of integers $\leq n$ of the form kp^a is asymptotic to $((n/k)^{1/a})/\log(n)$.*

Proof. Both these formulas follow easily from the prime number theorem. □

Lemma 11. *Let k be a positive integer. Then the number of numbers $\leq n$ of the form kpq, where p, q are distinct primes, is asymptotic to $(n \log\log n)/(k \log n)$.*

Proof. We use a Theorem of Hardy and Wright [2, Thm. 437], which states that the number of squarefree numbers less than n with k prime factors, $k \geq 2$ is asymptotic to $\frac{n(\log\log n)^{k-1}}{(k-1)! \log n}$. Setting $k = 2$ and using the same techniques as in the proof for Lemma 10 yields the desired result. □

Lemma 12. *The numbers of tau numbers $\leq n$ of the form $36pq$ with p, q distinct primes > 3 is asymptotic to $(n \log\log n)/(36 \log n)$.*

Proof. By Lemma 11 the number of positive integers $\leq n$ of the form $36pq$ is asymptotic to

$$\frac{n \log\log n}{36 \log n} \tag{1}$$

The number of tau numbers of the form $36pq$ with p, q prime numbers > 3 is the number of numbers of the form $36pq$ minus the number of numbers of the form $36 \cdot 2 \cdot p$ or $36 \cdot 3 \cdot p$. Thus, using 1, together with Lemma 11 the number of such numbers is asymptotically

$$\frac{n \log\log n}{36 \log n} - \frac{n}{72 \log n} - \frac{n}{108 \log n} - \tag{2}$$

which is asymptotic to the first term. □

Lemma 13. *For any fixed real number $r < 1$ we have $T(n) > \frac{rn \log\log n}{36 \log n}$ for all n sufficiently large.*

Proof. This inequality follows from Lemmas 12 and 9. □

Theorem 14. *For any real number k we have $T(n) > k\pi(n)$ for all n sufficiently large.*

Proof. Clearly for any positive $r < 1$, and any k, for all sufficiently large n,

$$\frac{rn \log\log n}{36 \log n} > kn/\log n. \tag{3}$$

Since $\pi(n) \sim n/\log n$, for all sufficiently large n, $\frac{rn \log\log n}{36 \log n} > k\pi(n)$. By applying Lemma 13, we conclude that for all sufficiently large n, $T(n) > k\pi(n)$. □

Corollary 15.

For any $b > 0$ there are at most a finite number of integers n such that $T(n) > b\pi(n)$.

Proof. This result follows immediately from Theorem 14. □

Corollary 16. *There are at most a finite number of integers n such that $T(n) < .5\pi(n)$.*

Proof. Let $b = .5$ in the above corollary. □

Theorem 14 also implies that $T(n) > \pi(n)$ for all sufficiently large n. Colton gave a table of $T(n)$ showing that $T(10^7)$ is about $.59\pi(n)$. So $T(n)$ must not drastically exceed $\pi(n)$ until n becomes very large. This is a good example of the law of small numbers. In fact, we can construct an even better example of the law of small numbers.

Definition. An integer n is *rare* if $\tau(n) \mid n$, $\tau(n) \mid \phi(n)$ and $\tau(n) \mid \sigma(n)$, where $\phi(n)$ is the number of integers less than or equal to n and relatively prime to n, and $\sigma(n)$ is the sum of the divisors of n.

Let $R(n)$ be the number of rare numbers $\leq n$. We can use a construction similar to the one above to show that if p, q are distinct primes, not equal to 2,3 or 7, then $672pq$ is rare. Using similar logic to that above, we can conclude for any k, for all sufficiently large n, $R(n) > k\pi(n)$. Thus, although there are only two rare numbers less than 100 (namely, 1 and 56) and there are 25 primes less than 100, for all sufficiently large n, $R(n) > \pi(n)$.

It would be interesting to establish a good upper bound beyond which this inequality always holds. In the above construction, we have "cheated" slightly since n such that $\tau(n) \mid \sigma(n)$ have density 1. Note that we could have proven tau-prime density result result proving that all numbers of the form kpq for any k exceeds the density of the primes just like those of the form $36pq$ and then looking at the subset of tau numbers of the form $36pq$. There are other sequences of tau number that could have been used to the same effect, such

as those of the form $80pqr$ where p, q and r and are distinct odd primes not equal to 5. It is not difficult to generalize the above theorem to show that for any k,

$$((n \log\log n)^k)/\log n = o(T(n)). \tag{4}$$

Finding an actual asymptotic formula for $T(n)$ is more difficult. We can address this issue with certain heuristics. We know that $\tau(n)$ is of average order $\log n$. Since n is a tau number when $n \bmod \tau(n) = 0$ and $n \bmod \tau(n)$ can have $\tau(n)$ values, we would expect the probability of a random integer to be a tau number to be $1/\log(n)$. However, integrating this yields $n/\log n$ as the asymptotic value, which is too low even if we multiply it by a constant. However, almost all integers have about $\log n^{\log 2}$ divisors [2, p. 265], and a few integers with large tau values bring up the average. If we use the same logic as above and note that almost all tau numbers are divisible by 4, it makes sense to take 1/4th of the integral of $(\log n)^{-\log 2}$. Thus we arrive at the following conjectured relation:

Conjecture 17.

$$T(x) \sim (1/4) \int_3^x \log u^{-\log 2} du. \tag{5}$$

This conjecture gives an approximate values of 42854 for $T(10^6)$ and 381659 for $T(10^7)$. Colton's table gives $T(10^6) = 44705$ and $T(10^7) = 394240$. Our heuristic approximation seems to slightly underestimate the actual values, being 95.8% and 96.8% of the actual values, respectively. This underestimate is expected since the integral approximation ignores the tau numbers congruent to 1 or 2 mod 4. In fact, we conjecture that for all sufficiently large n the integral underestimates $T(n)$. Since the relationship between $\tau(n)$ and $(\log n)^{\log 2}$ is weak, it seems much safer to conjecture the weaker:

$$\log T(x) \sim \log \left(\frac{1}{4} \int_3^x (\log u)^{-\log 2} du \right). \tag{6}$$

It is possible, using the known bounds for the various asymptotic formulas here to obtain an actual upper bound above which Colton's conjecture must be true. It is not difficult, although computationally intensive, to use a few different generators along with 36 to obtain a bound of 10^{37}. However, using a more general method it is possible to lower the bound to slightly over $7 \cdot 10^{13}$.

Lemma 18. $2 \mid n/\tau(n)$ *iff for any prime p such that p does not divide n, np is a tau number.*

Example: $2 \mid 8/\tau(8) = 8/4 = 2$ and $8p$ is a tau number for all odd primes p. The proof is left to the reader.

Definition. A tau number n such that for any prime p, if p does not divide n then np is a tau number, is called a *p-generator*. Any tau number of the form np is said to be *p-generated* by n.

Thus, in the example above, 8 is a p-generator. Thus Lemma 18 can be restated as follows: n is a p-generator iff $2 \mid n/\tau(n)$. In what follows, both forms of this lemma are used interchangeably.

Notation. Let $\omega(n)$ denote the number of distinct prime factors of n. Let $g(n)$ denote the largest prime factor of n. Let $G(n) = n(n+1)/2$. Let P_n denote the nth prime, with $P_1 = 2$.

Lemma 19. *Let k be a p-generator. The number of tau numbers $\leq n$ of the form kp is at least $\pi(n/k) - \omega(n)$.*

Proof. Left to the reader. □

Lemma 20. *If $a_1, a_2, \ldots a_s$ are p-generators, then for any n the number of tau numbers $\leq n$ p-generated by any a_i is at least*

$$\sum_{i=1}^{s} \pi(n/a_i) - \pi(g(a_i)). \tag{7}$$

Proof. The proof follows from Lemma 18 when we observe that for any a_i, a_j where $k = \pi(g(a_i))+1$ and $m = \pi(g(a_j))+1$, the sets $\{a_iP_k, a_iP_{k+1}, a_iP_{k+2}, \ldots\}$ and $\{a_jP_m, a_jP_{m+1}, a_jP_{m+2}, \ldots\}$ have no common elements. □

Lemma 21. *If $a_1, a_2, a_3, \ldots$ are p-generators then for any n the number of tau numbers $\leq n$ p-generated by any a_i is at least $A\pi(n) - B$ where $A = \sum_{i=1}^{k} 1/a_i$ and $B = \sum_{i=1}^{k}(\pi(g(a_i))+1)$.*

Proof. This proof follows immediately from Lemma 19 since each summand in A introduces an error of at most 1. □

Theorem 22. *For all $n > 7.42 \cdot 10^{13}$ we have $T(n) > \pi(n)/2$.*

Proof. It has been shown by Dusart [6] that for all $n > 598$, the inequality

$$(n/\log n))(1 + .992/\log n) < \pi(n) < (n/\log n)(1 + 1.2762/\log n)$$

holds. We use all the p-generators less than or equal to 28653696 together with Lemma 21 to obtain a lower bound for the number of tau numbers, and then demonstrate that for all n greater than $7.42 \cdot 10^{13}$, this exceeds $.5(n/\log n)(1 + 1.2762/\log n)$ and thus exceeds $.5\pi(n)$. Using a simple computer program, it is not difficult to calculate that there are exactly 413980 p-generators less than 28653696. Their A value as in Lemma 21 is over .508. It is not difficult to see that

$$\begin{aligned} B &< G(\pi(413980/36)) + G(\pi(413980/80)) + G(\pi(413980/96)) + (413980 - \pi(413980/36) \\ &- \pi(413980/80) - \pi(413980/96)) - \pi(413980/128). \end{aligned}$$

Calculating the relevant values and evaluating the above expression yields $B < 8694520815$. Thus, for all $n > 598 \cdot 28653696$, we have $T(n) > .508(n/\log n)(1+.992/\log n) - 8694520815$. For all $n > 10^{13.87}$, $508(n/\log n)(1+.992/\log n) - 8694520815 > .5(n/\log n)(1+1.2762/\log n)$. Since $10^{13.87} < 7.42 \cdot 10^{13}$ we conclude that for all $n > 7.42 \cdot 10^{13}$, we have $T(n) > .5\pi(n)$. □

The high density of the tau numbers and their relationship to the primes motivates the comparison of the two types of integers.

Theorem 23. *The sum of the reciprocals of the tau numbers diverges.*

Proof. The result follows immediately by observing that 8 is a p-generator and that the sum of the reciprocals of the primes diverges. □

There is a famous still unsolved conjecture, by Polignac, that for any positive even integer k, there exist primes p, q such that $k = p - q$ [4]. It seems reasonable to make an identical conjecture about the tau numbers. Indeed, the existence of infinitely many odd tau numbers makes one wonder whether every positive integer is the difference of two tau numbers. However, there are some odd integers which are not the difference of two tau numbers despite the fact that the density of the tau numbers is much higher than that of the primes.

Theorem 24. *There do not exists tau numbers a, b such that $a - b = 5$.*

Proof. Suppose, contrary to what we want to prove, that there exist tau numbers a, b such that $a - b = 5$. By Theorem 7 we know that every tau number is congruent to $0, 1, 2$ or $4 \pmod 8$. Thus, we have $b \equiv 4 \pmod 8$ and $a \equiv 1 \pmod 8$. Hence 4 is the highest power of two which divides b. Thus $\tau(4) = 3 \mid \tau(b)$, and since $\tau(b) \mid b$ we get $b \equiv 0 \pmod 3$. Then $a \equiv 2 \pmod 3$, which is impossible since a is an odd tau number and hence a square. □

Goldbach made two famous conjectures about the additive properties of the primes. Goldbach's strong conjecture is that any even integer greater than 4 is the sum of two primes. Goldbach's weak conjecture is that every odd integer greater than 7 is the sum of the three odd primes. It is easy to see that the weak conjecture follows from the strong conjecture [4].

However, Colton's congruence results of Theorem 7 imply that any $n \equiv 7 \pmod 8$ cannot be the sum of two tau numbers.

The following theorems and the next conjecture are the tau equivalents of Goldbach's conjecture.

Theorem 25. *(a) If Goldbach's weak conjecture is true than any positive integer can be expressed as the sum of* 6 *or fewer tau numbers.*

(b) If Goldbach's strong conjecture is true than every positive integer is the sum of 5 *or fewer tau numbers.*

Proof. (a) Assume Goldbach's weak conjecture. Let A be the set of integers n such that $8n$ is a tau number or $n = 0$. Consider $x = 8k$ for some odd $k > 7$. Since every odd prime is an element of A, $k = a_1 + a_2 + a_3$ for some a_1, a_2, a_3 element A. So $8k = 8a_1 + 8a_2 + 8a_3$. Since $8k = 8 \bmod 16$, we conclude that for any $x \equiv 8 \bmod 16$, x is the sum of at most three tau numbers. It is easy to see from this result and the fact that $1, 2, 8, 9, 12$ are all tau, that any

integer greater than 56 can be expressed as the sum of 6 or fewer tau numbers. It is easy to verify that every integer under 56 can be expressed as the sum of 6 or fewer tau numbers. Thus, if Goldbach's weak conjecture is true than every integer is the sum of 6 or fewer tau numbers.

Case (b) follows by similar reasoning. □

Theorem 26. *For all sufficiently large n, n can be expressed as the sum of 6 or fewer tau numbers.*

Proof. This result follows from applying Vinogradov's famous result that every sufficiently large odd integer is expressible as the sum of three or fewer primes and using the same techniques as in the previous theorem. □

The techniques in the previous theorems can also be used to prove the following corollary.

Corollary 27. *If Goldbach's weak conjecture is true than any positive integer not congruent to 7 mod 8 can be expressed as the sum of 5 or fewer tau numbers. If Goldbach's strong conjecture is true than every positive integer not congruent to 7 mod 8 is the sum of 4 or fewer tau numbers.*

Note that since the set A introduced in the proof of Theorem 25 contains many elements other than the primes, even if either the weak or the strong Goldbach conjectures fail to hold, it is still very likely that all integers can be expressed as the sum of six or fewer tau numbers.

We make the following

Conjecture 28. *Every positive integer is expressible as the sum of 4 or fewer tau numbers.*

It seems that the above conjecture cannot be proven by methods similar to those used in Theorem 25.

For any n, Bertrand's postulate states that there is a prime between n and $2n$. The equivalent for tau numbers is the next theorem:

Theorem 29. *For any integer $n > 5$ there is always a tau number between n and $2n$.*

Proof. This result follows immediately from the fact that 8 is a p-generator. □

Another unsolved problem about primes is whether there is always a prime between n^2 and $(n+1)^2$. The fact that the tau numbers have a much higher density than the primes motivates the following conjectures:

Conjecture 30. *For any sufficiently large integer n, there exists a tau number t such that $n^2 < t < (n+1)^2$.*

Conjecture 31. *For any integer n, there exist a tau number t such that $n^2 \leq t \leq (n+1)^2$.*

Dirichlet's Theorem states that when $\gcd(a, b) = 1$ then the set $\{n \ : \ an + b \text{ is prime}\}$ is infinite. This theorem is equivalent to there being an infinite number of primes in any arithmetic progression aside from certain trivial cases. For tau numbers the equivalent problem becomes:

Conjecture 32. *Any arithmetic progression of positive integers which contains a tau number contains infinitely many tau numbers.*

For many arithmetic progressions that have no terms divisible by 4, it is often easy to see that they do not contain any tau numbers, since the sequences contain all odd non-quadratic residues mod some k, or twice such residues. Examples include the progressions $3, 7, 11, 15 \ldots$ and $6, 14, 22, 30 \ldots$ There are many other arithmetic progressions which fail to contain tau numbers and the proofs require a little arithmetic. The arithmetic progression $4, 28, 52, 76 \ldots$ is one example.

Theorem 33. *If $n \equiv 4 \pmod{24}$, then n is not a tau number.*

Proof. Let n be a tau number and $n \equiv 4 \pmod{24}$. Then 4 is the highest power of 2 dividing n, so $3 \mid n$ which is impossible. □

The concept of p-generators can be be generalized.

Definition. For a list of positive integers $a_1, a_2, a_3 \ldots a_k$, n is an $(a_1, a_2, \ldots a_k)$-*generator* if for all k-tuples of distinct primes $(p_1, p_2, \ldots, p_k)$ which do not divide n, $np_1^{a_1}p_2^{a_2} \cdots p_k^{a_k}$ is a tau number. Such tau numbers are said to be *generated by* n.

Note: Whenever convenient, we assume the a_i in the above definition are in increasing order. The earlier idea of the p-generator now becomes a (1)-generator. Under this notation Lemma 9 can be reexpressed as follows: 36 is a $(1, 1)$-generator.

Definition. A tau number n is said to be a *primitive tau number* if n is not generated by any k.

Definition. m is said to be an *ancestor* of n if m generates n or m generates an ancestor of n. It is not difficult to see that this recursive definition is well-defined.

Example: 9 is an ancestor of 180 since 180 is generated by 36 and 36 is generated by 9.

Definition. Let $h(n)$ be the number distinct sets of positive integers greater than one such that the product of all the elements of the set is n.

The following theorem summarizes the basic properties of generators. No part is difficult to prove and the proofs are left to the reader.

Theorem 34. *(a) There exist infinitely many primitive tau numbers.*

(b) For any $a_1, a_2, a_3 \ldots a_k > 0$ there exist infinitely many n such that n is a $(a_1, a_2 \ldots a_k)$-generator.

(c) *For any tau number $n > 2$ there exist $a_1, a_2, a_3 \dots a_k$ such that n is an $(a_1, a_2, a_3 \dots a_k)$-generator. In particular, n is a $(n/\tau(n) - 1)$-generator.*

(d) *Apart from the order of the exponents any given tau number has $\sum_{d|n/\tau(n)} h(d)$ generators.*

(e) *If for some $a_1, a_2, \dots a_k$ n is an $(a_1, a_2, \dots, a_k)$-generator then for any $0 < j < k$, n is a $(a_1, a_2, \dots, a_j)$-generator.*

(f) *If m, n are relatively prime tau numbers where n is a $(a_1, a_2, \dots, a_k)$-generator then mn is also a $(a_1, a_2, \dots, a_k)$-generator.*

(g) *If m, n are relatively prime tau numbers and n is an $(a_1, a_2, \dots, a_k)$-generator and m is a $(b_1, b_2, \dots, b_j)$-generator then mn is an $(a_1, a_2, \dots, a_k, b_1, b_2, \dots, b_j)$-generator.*

(h) *Every tau number n is either a primitive tau number or has exactly one ancestor m which is a primitive tau number, which is defined to be the primitive ancestor of n.*

The consideration of the low density of tau numbers with a given ancestor and the low density of primitive tau numbers motivates the following definitions and accompanying conjectures.

Definitions. Let $T_k(n)$ denote the number of tau numbers less than or equal to n with k as an ancestor. Let $PT(n)$ denote the number of primitive tau numbers less than or equal to n.

Conjecture 35. *For any k, $\lim_{n\to\infty} T_k(n)/T(n) = 0$.*

A proof of the above conjecture for even n is not dificult and is left to the reader.

Conjecture 36. $\lim_{n\to\infty} PT(n)/T(n) = 0$.

Theorem 34 (c) and (d) motivate an investigation into the properties of the function $t(n) := n/\tau(n)$. Clearly this function is an integer iff n is a tau number. Not every positive integer is in the range of $t(n)$.

To prove that not every integer is in the range of t we need a few lemmas.

Lemma 37. $\tau(n) < 2n^{1/2}$ *for all* $n \geq 1$.

Proof. Clearly, for any divisor d of n, if $d \geq n^{1/2}$ then $n/d \mid n$ and $n/d \leq n^{1/2}$ Thus we can make pairs of all the divisors of n with each one number of each pair less than $n^{1/2}$. Since there are at most $n^{1/2}$ pairs, we get $\tau(n)) < 2n^{1/2}$. □

Lemma 38. *For all $n, t(n) > .5n^{1/2}$.*

Proof. This follows immediately from Lemma 37. □

Lemma 39. *For any real number r, if $n/\tau(n) \leq r$ then $n \leq 4r^2$.*

Proof. This follows immediately Lemma 38. □

The next lemma is easy to prove and the proof is omitted.

Lemma 40. *For any prime p, tau number n, and integer $k \geq 1$, if $p^{p^k-1} \mid n/\tau(n)$ then $p^{p^k} \mid n$.*

Theorem 41. *There does not exist n such that $t(n) = 18$.*

Proof. By Lemma 39 we merely need to verify the claim for $n \leq 1296$. Using Lemma 40 we need only to check the multiples of 108 which is easy to do. □

Kennedy and Cooper's result that the tau numbers have density 0 [3], along with Lemma 39, motivates the following conjecture:

Conjecture 42. *There exist infinitely many positive integers k such that for all n, $t(n) \neq k$.*

We can prove a much weaker result than the above conjecture. We show that there are integers which are not in the range of $t(2n+1)$. First we need two lemmas corresponding to the earlier lemmas.

Lemma 43. *For any odd integer n, $\tau(n) \leq \lceil n^{1/2} \rceil$.*

Proof. This follows from a modification of Lemma 21. □

Lemma 43 leads directly to Lemma 44:

Lemma 44. *For any odd integer n, $t(n) \geq \lfloor n^{1/2} \rfloor$.*

Proof. This follows from Lemma 43. □

Theorem 45. *There exist infinitely many odd integers k such that $t(n) \neq k$ for all odd n. Specifically, whenever k is an odd prime greater than 3, $t(n) \neq k$ for all odd n.*

Proof. Assume that for some prime $p > 3$, $t(n) = p$. So by Lemma 44, $p > \lfloor n^{1/2} \rfloor$. So $p + 1 > n^{1/2}$ and thus $p^2 + 2p + 1 \geq n$. Now since n is an odd tau, n is a perfect square. So $p^2 \mid n$. But $n \leq p^2 + 2p + 1$. Thus $n = p^2$ which is impossible. □

Using a similar method as the proof of the last theorem, we get the following slightly stronger result:

Theorem 46. *Let p be a prime > 3. Let n be a tau number such that $t(n) = p$. Then $4|n$.*

Note that since almost all tau numbers are divisible by 4, the above result is a far cry from Conjecture 42. In fact, for any odd prime p we have $t(8p) = p$.

Colton also has made the conjecture that for any $n > 2$, the number $n!/3$ is always a tau number. The following heuristic suggests a related conjecture:

Conjecture 47. *For any positive integers a, b with a odd, there exists an integer k such that $(a/b)n!$ is a tau number for all $n > k$.*

We give a heuristic reason to believe this conjecture. Let a and b be integers. Consider some n much larger than a and b. Now on average, for some prime p, it is easy to see that the mean number of times p appears in the factorization of n is about $1/(p-1)$. For large n, the change made by a and b in the number of factors is small. So for any prime p in the factorization of $(a/b)n!$, p is raised to a power approximately equal to $n/(p-1)$. and there are about $n/\log n$ primes $\leq n$. Hence the highest power of p dividing $\tau((a/b)n!))$ is about $n/((p-1)\log n)$. For all sufficiently large n, $n/(p-1)$ is much larger than $n/((p-1)\log n)$. Since every prime exponent of $\tau((a/b)n!))$ is less than the corresponding exponent for $(a/b)n!$ we conclude that $\tau((a/b)n!)) \mid (a/b)n!$.

Note: The reason a must be odd in the above conjecture is subtle. Let $n = 2^k$. It is not difficult to see that $2^{n-1} \mid n!$. Thus if a has some power of 2 dividing it than one can force the power of 2 in $an!$ to be slightly over n, such as 2^{n+2}, in which case $(2^k) + 3 | \tau(an!)$ and $2^k + 3$ may be prime infinitely often, in which case $\tau(an!)$ does not divide $an!$ for any such k. Examples other than $2^k + 3$ would also suffice. It is easy to see that this problem only arises with 2 and not any other prime factor.

We can prove a large portion of this conjecture. We first require a few definitions.

Definition. Let $\nu_p(n)$ denote the largest integer k such that $p^k \mid n$.

Lemma 48. *n is a tau number iff for any prime $p, \nu_p(\tau(n)) \leq \nu_p(n)$.*

Proof. This follows immediately from the definition of L. □

Lemma 49. *$\lfloor n/p \rfloor \leq \nu_p(n!) \leq \lceil n/(p-1) \rceil$. Furthermore, $\nu_p(n!) \sim n/(p-1)$.*

Proof. The proof is left to the reader. □

Lemma 50. *For any positive integers a and b, and prime $p, \nu_p((a/b)n!) \sim n/(p-1)$.*

Proof. Let a and b be positive integers and p prime. Without loss of generality assume $\gcd(a, b) = 1$. For all n, $\nu_p(n!) - \nu_p(b) \leq \nu_p((a/b)n!) \leq \nu_p(n!) + \nu_p(a)$. Now applying Lemma 49, and noting that $\nu_p(b)$ and $\nu_p(a)$ are constant with respect to n, we conclude that $\nu_p((a/b)n!) \sim n/(p-1)$. □

Theorem 51. *Let a and b be positive integers, and p prime. For all sufficiently large n the highest power of p that divides $\tau((a/b)n!)$ also divides $(a/b)n!$. That is, $\nu_p(\tau((a/b)n!)) \leq \nu_p((a/b)n!)$.*

Proof. Let a and b be positive integers and let p be a prime. Without loss of generality assume $\gcd(a, b) = 1$. We thus need to find, for all sufficiently large n, an upper bound $U_p(n)$ for $\nu_p(\tau((a/b)n!))$ and show that there is a constant $k < 1$ such that for all sufficiently large n, the inequality $U_p(n)/(n/p) < k$ holds. We consider two cases: $p = 2$ and $p > 2$.

Case I: $p = 2$. Thus we need to find an upper bound $U_2(n)$ for $\nu_2(\tau((a/b)n!))$ such that $U_2(n)/(n/p) < k$ for all sufficiently large n and some constant $0 < k < 1$. For all sufficiently large n, every prime less or equal to $n/2$ which does not divide a can contribute at most $(\log n)/(\log 2)$ to $\nu_2(\tau((a/b)n!))$. Every prime between $n/2$ and n contributes 1 to $\nu_2(\tau((a/b)n!))$. Thus

$$\nu_2(\tau(a/b))n! \leq \pi(n/2)(\log_2 n) + \pi(n) - \pi(n/2) + A_1, \tag{8}$$

where A_1 is some constant depending solely on a. Now applying the prime number theorem yields, for any $\epsilon > 0$ and all sufficiently large n,

$$\nu_2(\tau((a/b)n!)) < \frac{(1+\epsilon)(n\log_2 n)}{2\log n} + \frac{(1+\epsilon)n}{2\log n}, \tag{9}$$

which, when all the logarithms are made natural, becomes: For any $\epsilon > 0$ and all sufficiently large n,

$$\nu_2(\tau((a/b)n!)) \leq \frac{(1+\epsilon)n}{2\log 2} + \frac{(1+\epsilon)n}{2\log n} \tag{10}$$

Now fix ϵ as some number less than $2\log 2 - 1$and let such a resulting function be $U_2(n)$. It is easy to see that the function satisfies the desired inequality.

Case II: Let $p > 2$. Using similar logic to that used in the earlier case we conclude that for any $\epsilon > 0$ and all sufficiently large n

$$\nu_2(\tau((a/b)n!)) \leq \frac{(1+\epsilon)(n+p)(\log_p n)}{p\log((n+p)/p)} \leq \frac{(1+\epsilon)(n+p)}{p\log p} \tag{11}$$

Fixing ϵ as some number less than $p\log p - 1$ and making the rightmost part of (11) equal to $U_p(n)$ gives the desired result. □

Note that one could use the earlier cited bounds of Dusart to make the above proof constructive.

4 Generalizations

It is possible to generalize the concept of tau number. First consider that the definition of tau number is equivalent to $n \bmod \tau(n) = 0$. We now say that n is a tau number relative to k if $n \bmod \tau(n) = k$. Of course, $k = 0$ gives the ordinary tau numbers and it is easy to see that every odd prime is a tau number relative to 1. Also it is easy to see that any n is a tau number relative to k, for some k. The main result about integers which are tau numbers relative to k is the following theorem:

Theorem 52. *For any odd k there exists an infinitely many n such that n is a tau number relative to k.*

Proof. Let k be an odd integer. We claim that there exist arbitrarily large distinct primes, p, q and r such that $p^{r-1}q \bmod \tau(p^{r-1}q) = k$. This is equivalent to showing that $p^{r-1}q \equiv k \pmod{2r}$. By Fermat's Little Theorem, $p^{r-1} \equiv 1 \pmod{r}$. Thus we merely need to show that there exist arbitrarily large primes q such that $q \equiv k \pmod{2r}$, which follows immediately from Dirichlet's theorem about primes in arithmetic progressions. □

I make the following conjecture.

Conjecture 53. *For any k, there exist infinitely many n such that n is a tau number relative to k.*

It is not difficult to prove many special cases of this conjecture k where some p is assumed not to divide k, as in Theorem 51. In fact we shall prove the above conjecture by examining a larger generalization:

Let $Q(n)$ be a polynomial with integer coefficients. An integer n is said to be a tau number relative to $Q(n)$ if $\tau(n) \mid Q(n)$. In this generalization, tau numbers are the case where $Q(n) = n$.

Clearly the above conjecture follows from the next theorem:

Theorem 54. *For any $Q(n)$ with integer coefficients, there exist infinitely many n such that $\tau(n) \mid Q(n)$.*

Proof. Without loss of generality, assume the leading coefficient of $Q(n)$ is positive. If the constant term is 0 then any tau number is a tau number relative to $Q(n)$. So assume the constant term is non-zero. Chose some c such that $Q(c) \geq 1$ and $(Q(c), c) = 1$. Now by Dirichlet's theorem there exist infinitely many primes p such that $p \equiv c \pmod{Q(c)}$. For any such p, $p^{Q(c)-1}$ is a tau number for $Q(n)$ since $\tau(p^{Q(c)-1}) = Q(c)$ and $Q(c) \mid Q(p)$. □

If n is a tau number, then $\tau(n)$ has a similar as possible a factorization to n in some sense. Tau numbers maximize $\gcd(n, \tau(n))$. This motivates the following definition:

Definition. The positive integer n is said to be an *anti-tau number* if $\gcd(n, \tau(n)) = 1$.

Note an integer n is a tau number iff $\operatorname{lcm}(n, \tau(n)) = n$. Thus in some sense, an integer n is a tau number if $\operatorname{lcm}(n, \tau(n))$ is minimized. Now, if $\gcd(n, \tau(n)) = 1$ then $\operatorname{lcm}(n, \tau(n)) = n\tau(n)$. Thus the anti-tau numbers represent the numbers that maximize $\operatorname{lcm}(n, \tau(n))$.

Note that if two tau numbers are relatively prime then their product is a tau number. But as the pairs (3,4), (3,5) and (13,4) demonstrate, the product of two relatively prime anti-tau numbers can be a tau number, an anti-tau number, or neither. The following Theorem summarizes the basic properties of anti-tau numbers.

Theorem 55. *(a) The only tau number that is also an anti-tau number is* 1.

(b) If a is an even anti-tau number, then a is a perfect square.

(c) For $a, b > 1$, $\gcd(a, b) = 1$ a is a tau number and b is an anti-tau number then ab is neither a tau nor an anti-tau number.

(d) *Any odd square-free number is an anti-tau number.*

(e) *For any constant integer C, where primes $a_1, a_2 \dots a_k$ are all less than C and then for some primes distinct $p_1, p_2, \dots ...p_k$ all greater than C, then for any positive integers, $b_1, b_2 \dots b_k$ the number $(a_1^{p_1^{b_1}-1})(a_2^{p_2^{b_2}-1}) \cdots (a_k^{p_k^{b_k}-1})$ is an anti-tau number.*

Part (b) of the above theorem shows that the anti-tau numbers are unlike the tau numbers in more than one way, since a corresponding rule exists about the odd tau numbers. Part (c) can be considered a cancellation law of sorts. Parts (d) and (e) motivates the following conjecture. Let $AT(n)$ denote the number of numbers $\leq n$ that are anti-tau numbers.

Conjecture 56. *For all $n > 3$, the inequality $T(n) < AT(n)$ holds.*

The following results indicate the above conjecture is true for all sufficiently large n.

Theorem 57. *The density of the anti-tau numbers is at least $3/\pi^2$.*

Proof. This follows immediately from Theorem 55 (d) and the fact that the square free numbers have density $6/\pi^2$. □

Theorem 58. *For all sufficiently large n, $T(n) < AT(n)$. In fact $\lim_{n\to\infty} T(n)/AT(n) = 0$.*

Proof. This theorem follows immediately from the density of the anti-tau numbers together with Kennedy and Cooper's result that the tau numbers have zero density. □

Conjecture 56 is intuitive. In order for n to be not tau, all $\tau(n)$ needs is to have too high a prime power in its factorization or a prime that is not a factor of n. However, in order for n not to be anti-tau, $\tau(n)$ needs a prime factor of n, a much stronger condition.

Colton also conjectured the non-existence of three consecutive tau numbers. We shall prove the slightly stronger result that if a is an odd integer such that $a, a+1$ are both tau numbers then $a = 1$.

A few remarks: Colton started by assuming that he had three tau numbers $a-1, a, a+1$ and then showed using the basic congurence restrictions on the tau numbers that a was an odd perfect square and $a+1$ was twice an odd perfect square. However, it is easy to see that this restriction applies equally well if we substitute the assumption that $a-1$ is a tau number for assuming a is odd. Colton then examined the resulting Diophantine equation $x^2 + 1 = 2y^2$ and was able to produce other restriction on the necessary properties of the triple based on this well-known equation.

Theorem 59. *If a is an odd integer such that $a, a+1$ are tau numbers then $a = 1$.*

Proof. By the above comments, we really need to look at the Diophantine equation $x^2+1 = 2y^2$. Now it is a well known result that any odd divisor of x^2+1 must be congruent to 1 (mod 4) [5]. So every odd divisor of $2y^2$ must be congruent to 1 (mod 4). But $2y^2$ is a tau number, so every odd prime in its factorization must be raised to an exponent divisible by 4 since otherwise $2y^2$ would be divisible some number of the form 3 mod 4. Thus $2y^2 = 2w^4$

for some w. So we really need to solve $x^2 + 1 = 2w^4$. This is a Diophantine equation which has only the solutions $(x, w) = (1, 1)$ and $(x, w) = (239, 13)$ [7]. The second solution fails to yield a tau number and so $x = 1$. □

The known proofs that these are the only positive solutions of this final Diophantine equation are quite lengthy and involved. It would be interesting to find a way of proving the desired result without relying on the equation, or possibly, a simple proof that (1,1) is the only tau solution of the equation.
